ORFFYREUS'S WHEEL, in mechanics, is a machine so called from its inventor, which he asserted to be a perpetual motion. This machine, according to the account given of it by Gravesande, in his *Oeuvres Philosophiques*, published by Allemand, Amst 1774, consisted externally of a large circular wheel, or rather drum, 12 feet in diameter, and 14 inches deep; being very light, as it was formed of an assemblage of deals, having the intervals between them covered with waxed cloth, to conceal the interior parts of it. The two extremities of an iron axis, on which it turned, rested on two supports. On giving a slight impulse to the wheel, in either direction, its motion was gradually accelerated; so that, after two or three revolutions, it acquired so great a velocity as to make 25 or 26 turns in a minute. This rapid motion it actually preserved during the space of two months, in a chamber of the Landgrave of Hesse, the door of which was kept locked, and sealed with the Landgrave's own seal. At the end of that time it was stopped, to prevent the wear of the materials. The Professor, who had been an eye witness to these circumstances, examined all the external parts of it, and was convinced that there could not be any communication between it and any neighbouring room. Orffyreus, however, was so incensed, or pretended to be so, that he broke the machine in pieces, and wrote on the wall, that it was the impertinent curiosity of Professor Gravesande which made him take this step. The Prince of Hesse, who had seen the interior parts of this wheel, but sworn to secrecy, being asked by Gravesande, whether, after it had been in motion for some time, there was any change observable in it, and whether it contained any pieces that indicated fraud or deception? answered both questions in the negative, and declared, that the machine was of a very simple construction.

Hutton's Dictionary.

ORICOU, a new species of the vulture, discovered by Vaillant at Orange river in South Africa. As he thinks it unquestionably the most beautiful of its genus, and tells, as usual with him, a wonderful story about it, we have given a figure of this vulture in Plate XLI. Our traveller says, that it is more than three feet high, and eight or nine in breadth of wing. Its feathers, the general hue of which is a light brown, are of a particular kind on the breast, belly, and sides, where they are of unequal lengths, pointed, curved like the blade of a sabre, and bristle up distinct from each other. The feathers being thus separated, would disclose to view the skin on the breast, if it were not completely covered with a very thick and beautiful white down, which is easily seen between the ruffled plumage.

A celebrated naturalist has said, that "no bird has eye lashes or eye-brows, or, at least, hair round the eyes like that in quadrupeds." This assertion, advanced as a general law of Nature, is a mistake. Not only the oricou has this peculiarity, but we know of many other species in which it exists; such as, in general, all the calaos, the secretary, and several other birds of prey. Beside these eye lashes, the vulture in question has stiff black hairs on its throat. All the head and part of the neck are bare of feathers; and the naked skin, which is of a reddish colour, is dashed in certain places with blue, violet, and white. The ear, in its external circumference, is bounded by a prominent skin, which forms a sort

(A) In his work *De Mirabilibus Mundi*, at the end of his book *De Secretis Mulierum*, Amstelod. 1702, 12mo, p. 105. Experimentum mirabile quod facit hominem ire in ignem sine læsione, vel portare ignem vel ferrum ignitum sine læsione in manu. Recipe succum bismalvæ. et albumen ovi, et semen psylli et calcem, et pulveriza, et confice cum illo albumine ovi succum raphani; commisce; ex hac confectione illineas corpus tuum vel manum, et dimitte siccari, et postea iterum illineas, et post hoc poteris audacter sustinere ignem sine nocu-

fort of rounded conch, that muft neceffarily heighten the faculty of hearing in this fpecies. This kind of conch is prolonged for fome inches, and defcends down the neck; which induced our author to give it the name of *oricou*.

Its ftrength, he fays, muft be very confiderable, if we may judge from its mufcles and finews; and he is perfuaded, that there is not a ftronger among the whole order of carnivorous birds, not excepting the famous condor, which fo many travellers have feen, but of which their defcriptions are fo different as to render its exiftence extremely doubtful. But there was no occafion for this reafoning, and thofe inferences, if what he relates as facts deferve any credit. The oricou which he defcribes, he firft perceived perched on the carcafe of a hippopotamos, eagerly devouring its flefh. He fhot at it, and wounded it flightly; upon which, "though it had already gorged itfelf with a confiderable quantity of flefh (for upon opening it, he found in its ftomach no lefs a quantity than *fix pounds and a half*), yet its hunger and voracity were fuch, that it ftruck its beak into the carcafe when attempting to take wing, as if defirous of carrying the whole of it away.

"On the other hand, the weight of the flefh it had devoured rendering it the more heavy, it could not eafily rife; fo that we had time (fays he) to reach it before it was on the wing, and we endeavoured to knock it on the head with the but-ends of our mufkets. It defended itfelf a long time with great intrepidity. It bit or ftruck at our weapons with its beak, and its ftrength was ftill fo great, that every ftroke made a mark on the *barrel of the piece*."

ORIENT, the eaft, or the eaftern point of the horizon.

ORIENT *Equinoctial*, is ufed for that point of the horizon where the fun rifes when he is in the equinoctial, or when he enters the figns Aries and Libra.

ORIENT *Aeftival*, is the point where the fun rifes in the middle of fummer, when the days are longeft.

ORIENT *Hybernal*, is the point where the fun rifes in the middle of winter, when the days are fhorteft.

OROTAVA, a town in the ifland of Teneriffe, at the bottom of thofe mountains out of which the Peek rifes, neatly built of ftone, on an irregular furface. The moft remarkable object near it is a dragon's blood tree, of which the trunk meafures, at the height of ten feet from the ground, 36 feet in girth. Concerning this tree there is a tradition current in the ifland, that it exifted, of no inconfiderable dimenfions, when the Spaniards made the conqueft of Teneriffe, about three centuries ago; and that it was then, what it ftill is, a landmark, to diftinguifh the boundaries of landed poffeffions near it.

Diftant about three miles on the fea coaft is the puerto, or fea-port, of Orotava, where is carried on a confiderable degree of commerce, principally for the exportation of wine. It is chiefly, as at Madeira, in the hands of a few Britifh commercial houfes, which import, in return, the manufactures of Great Britain. Within a mile is a collection of living plants from Mexico, and other parts of the Spanifh dominions in America. From hence they are to be tranfplanted into Spain. It is an eftablifhment of fome expence; and, whatever may be its fuccefs, it fhews a laudable attention, on the part of that government, to the promotion of natural knowledge.

Orotchys.

OROTCHYS and BITCHYS, two tribes of Tartars, who were vifited by La Peroufe in 1787, and of whofe manners he gives fuch an account as renders it difficult to fay whether they have the beft claim to be called a favage or a civilized people. He fell in with a fmall village of them on the eaft coaft of Tartary, in a bay to which he gave the name of *Baie de Caftrie*, in Lat. 51° 29′ North, and Lon. 139° 39′ Eaft from Paris.

Their village, their employment, their drefs, and their apparent ignorance of all religion, befpoke them favages. Their village was compofed of four cabins, built in a folid manner, of the trunks of fir-trees, and covered with bark. A wooden bench compaffed the apartment round about; and the hearth was placed in the middle, under an opening large enough to give vent to the fmoke.

This village was built upon a tongue of low marfhy land, which appeared to be uninhabitable during the winter; but on the oppofite fide of the gulf, on a more elevated fituation, and expofed to the fouth, there was, at the entrance of a wood, another village, confifting of eight cabins, much larger and better built than the firft. Above this, and at a very fmall diftance, were three yourts, or fubterraneous houfes, perfectly fimilar to thofe of the Kamtfchadales, defcribed in the third volume of Captain Cook's laft voyage; they were extenfive enough to contain the inhabitants of the eight cabins during the rigour of the cold feafon; befides, on fome of the fkirts of this village were feen feveral tombs, which were larger and better built than the houfes; each of them enclofed three, four, or five biers, of a neat workmanfhip, ornamented with Chinefe ftuffs, fome pieces of which were brocade. Bows, arrows, lines, and, in general, the moft valuable articles of thefe people, were fufpended in the interior of thofe monuments, the wooden door of which was clofed by a bar, fupported at its extremities by two props.

Their fole employment feemed to be the killing and curing of falmon, of which they eat raw, the fnout, the gills, the fmall bones, and fometimes the entire fkin, which they ftript off with infinite dexterity. When the ftript falmon were carried to the huts, the women, in the moft difgufting manner, devoured the mucilaginous part of them, and feemed to think it the moft exquifite food. Every cabin was furrounded with a drying place for falmon, which remain upon poles, expofed to the heat of the fun, after having been during three or four days fmoked round the fire, which is in the middle of their cabin; the women, who are charged with this operation, take care, as foon as the fmoke has penetrated them, to carry them into the open air, where they acquire the hardnefs of wood.

The bones of the falmon fo cured were fcattered, and the blood fpread round the hearth; greedy dogs, though gentle and familiar enough, licked and devoured the remainder. The naftinefs and ftench of this people are difgufting. There is not perhaps anywhere a race of people more feebly conftituted, or whofe features are more different from thofe forms to which we attach the idea of beauty; their middle ftature is below four feet ten inches, their bodies are lank, their voices thin and feeble, like that of children; they have high

check

cheek bones, small blear eyes, placed diagonally; a large mouth, flat nose, short chin, almost beardless, and an olive coloured skin, varnished with oil and smoke. They suffer their hair to grow, and tie it up nearly the same as we do; that of the women falls loose about their shoulders, and the portrait which has just been drawn agrees equally well with their countenances as those of the men, from whom it would be difficult to distinguish them, were it not for a slight difference in the dress, and a bare neck; they are not, however, subjected to any labour, which might, like the American Indians, change the elegance of their features, if nature had furnished them with this advantage. Their whole cares are limited to the cutting and sewing their clothes, disposing of their fish to be dried, and taking care of their children, to whom they give the breast till they are three or four years of age.

With respect to dress, the men and little boys are clothed with a waistcoat of nankeen, or the skin of a dog or a fish, cut in the shape of a waggoner's frock. If it reach below the knee, they wear no drawers; if it do not, they wear some in the Chinese style, which fall as low as the calf of the leg. All of them have boots of seal's skin, but they keep them for the winter; and they at all times, and of every age, even at the breast, wear a leather girdle, to which are attached a knife in a sheath, a steel to strike a light with, a pipe, and a small bag to contain tobacco. The dress of the women is somewhat different; they are wrapped up in a large nankeen robe, or salmon's skin, which they have the art of perfectly tanning, and rendering extremely supple. This dress reaches as low as the ankle bone, and is sometimes bordered with a fringe of small copper ornaments, which make a noise similar to that of small bells. Those salmon, the skins of which serve for clothing, are never caught in summer, and weigh thirty or forty pounds.

Though they had neither priests nor temples, they seemed to be believers in sorcery, and took the motion of the Frenchmens hands, when writing, for signs of magic. Thus far they appeared savages.

Their sacred regard of property, their attention to their women, and the delicacy of their politeness to strangers, would, on the other hand, do honour to the most civilized nation. While Perouse and his people were in the bay, one of the families took its departure on a voyage of some length, and did not return during their stay. When he went away, the master of the family put some planks before the door of his house, to prevent the dogs from entering it, and in this state left it full of their effects. "We were soon (says our author) so perfectly convinced of the inviolable fidelity of these people, and their almost religious respect for property, that we left our sacks full of stuffs, beads, iron tools, and, in general, every thing we used as articles of barter, in the middle of their cabins, and under no other seal of security than their own probity, without a single instance of their abusing our extreme confidence; and on our departure from this bay, we firmly entertained the opinion, that they did not even suspect the existence of such a crime as theft."

Their attention to their women, so uncommon among savages, was displayed in their exempting them from hard labour; in their never concluding a bargain with the Frenchmen without previously consulting their wives; and in their reserving the pendent silver ear-rings and copper trinkets, which they purchased, for their wives and daughters. Of the delicacy of their manners to strangers, we shall give the following interesting instance in the words of Perouse's translator:

Observing with what repugnance they received presents, and how often they refused them with obstinacy, "I imagined (says Perouse) I could perceive, that they were perhaps desirous of more delicacy in the manner of offering them; and to try if this suspicion were well founded, I sat down in one of their houses, and after having drawn towards me two little children, of three or four years old, and made them some trifling caresses, I gave them a piece of rose-coloured nankeen, which I had brought in my pocket. The most lively satisfaction was visibly testified in the countenances of the whole family, and I am certain they would have refused this present, had it been directly offered to themselves. The husband went out of his cabin, and soon afterwards returning with his most beautiful dog, he entreated me to accept of it. I refused it, at the same time endeavouring to make him understand, that it was more useful to him than to me: but he insisted; and perceiving that it was without success, he caused the two children, who had received the nankeen, to approach, and placing their little hands on the back of the dog, he gave me to understand, that I ought not to refuse his children.

"The delicacy of such manners cannot exist but among a very polished people. It seems to me, that the civilization of a nation, which has neither flocks nor husbandry, cannot go beyond it. It is necessary to observe, that dogs are their most valuable property; they yoke them to small and very light sledges, extremely well made, and exactly similar to those of the Kamtschadales. These dogs, of the species of wolf dogs, and very strong, though of a middle size, are extremely docile, and very gentle, and seem to have imbibed the character of their masters."

ORTHODROMICS, in navigation, is great-circle sailing, or the art of sailing in the arch of a great circle, which is the shortest course: For the arch of a great circle is *orthodromia*, or the shortest distance between two points or places.

ORYCTEROPUS, the name given by M. Geoffroy, professor of zoology in the French museum of natural history, to the animal called by other zoologists *Myrmecophaga Capensis*. (See MYRMECOPHAGA, *Encycl.*) He considers it as a distinct genus, and seems indeed to have proved, by a comparison of the organs of the orycteropus with those of the *tatous dasypus* of Linnæus, and of the *myrmecophagi*, that this genus is intermediate, by its forms and habits, between those two families. It approaches to the *tatous* in its organs of mastication, and the form of the toes and nails, and in having a short and single cæcum, whilst that of the myrmecophagi is double, as in birds, by the reuniting of the bones of the os pubis, which are not articulated together in the myrmecophagi. The orycteropus, however, bears a relation to the last, since it has, like them, a very small mouth, whence its tongue, covered with hair, may be protruded to a considerable length. Finally, the habits of the orycteropus resemble those of the animals to which it approaches the most; it does not climb trees, but lives under the earth like the tatous;

tous; it feeds like them on roots, but alfo it hunts after anthills, like the myrmecophagi. Its fnout terminates in a blunt callous; a character which is peculiar to it. It may be diftinguifhed in the works of naturalifts by the following defcription:

Oryćteropus. Molar teeth (fix) with flat vertices; the body covered with hair.

The oryćteropus, as appears from the preceding, connects the tatous with the myrmecophagi and with the *pangolin manis* of Linnæus. The large foffile fpecies found in Paraguay, for which Citizen Cuvier has eftablifhed a new genus, under the name of *megatherium*, is intermediate between the floth and the myrmecophagus; and, laftly, the aftonifhing animal of New Holland, covered with briftles like the porcupine, fupported by very fhort legs, and of very fingular conformation, and with a head round at the occiput, terminating in a fnout, without teeth, very flender, long, and cylindrical, and defcribed by Mr George Shaw under the name of myrmecophaga aculeata, appears to have very ftriking relations to the pangolin and the oryćteropus: from hence it follows, that in confequence of thefe important acquifitions, we ought for the future to count, in the number of our natural orders, that of the *edentated*, or *edented*, confifting of the following genera: *Dafypus oryćteropus myrmecophaga*, and *aculeata, manis, myrmecophaga, megaterium* et *bradypus*.

OSCILLATION, in mechanics, vibration, or the reciprocal afcent and defcent of a pendulum.

Axis of OSCILLATION, is a line parallel to the horizon, fuppofed to pafs through the centre or fixed point about which the pendulum ofcillates, and perpendicular to the plane in which the ofcillation is made.

Centre of OSCILLATION, in a fufpended body, is a certain point in it, fuch that the ofcillations of the body will be made in the fame time as if that point alone were fufpended at that diftance from the point of fufpenfion. Or it is the point into which, if the whole weight of the body be collected, the feveral ofcillations will be performed in the fame time as before: the ofcillations being made only by the force of gravity of the ofcillating body.

OSCULATION, in geometry, denotes the contact between any curve and its ofculatory circle; that is, the circle of the fame curvature with the given curve, at the point of contact or of ofculation. See INVOLUTION in this *Suppl.*

OSCULATION alfo means the point of concourfe of two branches of a curve which touch each other. For example, if the equation of a curve be $y = \sqrt{x} + \sqrt[4]{x^5}$, it is eafy to fee that the curve has two branches touching one another at the point where $x = 0$, becaufe the roots have each the figns + and −.

OUADELIM, and LABDESSEBA, two tribes of Arabs inhabiting the *Sahara* or Great Defart of Africa, of whom almoft nothing was known to Europeans till the publication of Briffon's narrative of his fhipwreck and captivity among the latter tribe. He defcribes the Ouadelim and Labdeffeba as the moft formidable of all the interior tribes of Arabs, and as often extending their ravages to the very gates of Morocco. "Their hordes (he fays) are frequently intermingled with thofe of the Roufege, Rathidium, Chelus, Tucanois, and Ouadeli tribes, as they have no diftinct boundaries, and change their habitations as the defart affords pafturage and water. They are tall, handfome, ftout, and vigorous men. Their hair is briftled, and their nails, which they often ufe in battle, as long as claws; large hanging ears and a long beard give them a ftern ferocious air. The Ouadelim in particular are fierce, arrogant, and warlike, but foon difpirited by obftinate refiftance, efpecially when they have not a decided fuperiority in numbers. In their hordes they lodge by families, in tents which are covered with a thick cloth of camels hair, which the women fpin and weave upon a loom fo fmall, that they work fitting on the ground. The furniture of their tents confift of two large facks of leather, in which they keep old clothes and pieces of old iron, three or four goat fkins for holding milk and water, two large ftones for grinding their barley, a fmaller one for driving the pins of their tents, an ozier matting which ferves for a bed, a thick carpet for a covering, a fmall kettle, and fome wooden difhes, with pack faddles for their camels. The perfon who, befides thefe articles, poffeffes a few horfes, camels, fheep, and goats, is reckoned wealthy, as there are many Arabs who only poffefs fheep and goats. Except fore eyes and the cholic, they are fubject to few endemic difeafes. The firft diforder is caufed by the reflection of light from the burning fands of the defart, the other proceeds from the verdigreafe which contaminates all their victuals. Their kettles are not tinned, and never wafhed, fo that they are quite crufted over with verdigreafe, the virulence of which is probably diminifhed by the quantity of milk they ufe. When they refide long in one place, they fometimes plough the fpots which are moiftened by the rain, and fprinkle them with feed in a carelefs manner. Plentiful crops are often thus produced; but inftead of waiting till the grain attains maturity, they cut it down, and dry it over hot cinders. Treachery and perfidy are the innate vices of the Arabs; affaffinations are frequent; no man trufts the promife of another; no man makes a written agreement, as the poignard cancels all bonds and obligations. The men often relate their exploits to each other; the embellifhing of a ftory is fucceeded by a charge of falfehood, and the poignard folves every difficulty. The ancient rites of hofpitality, however, are practifed among thefe tribes in their utmoft extent. The Arab, who in the field is a rapacious plunderer, becomes liberal and generous as foon as he enters his tent. War is only a fpecies of rapine, and the victory is decided at the firft fhock. The Arab is devoid of fanguinary courage; he attacks only to plunder, and never thinks that booty is to be put in competition with his life. When the battle is ended, each party makes graves for the flain, and enclofe the tombs with mounds of ftones. The ages of the warriors are denoted by the fpace of ground which the grave occupies, and the funeral proceffion is clofed by the howls of the females.

"The women never affume the name of their hufbands, and never eat with them at meals. They are faithful to their hufbands, and cannot be divorced except by the decree of the feniors of the horde. The Arabs difplay their opulence by the ornaments of their women, whofe ears, arms, and legs, are generally adorned with rings of gold and filver. An Arab beauty muft have long teeth fhooting out of her mouth, a body extremely thick, and limbs of the longeft fize. At the birth of a fon, every woman, to teftify her joy, blackens

Ouadelim. er, her face for 40 days. At the birth of a daughter, she only daubs the half of her face during the space of 20 days. A mother treats her son with the same respect as her husband, almost as soon as he is able to walk; she prepares his food, serves him, and eats when he has finished his repast. In the education of their young men, the most important acquisitions are, dexterity in the use of the poignard, skill in embowelling their enemies with their long nails, and a plausible air in uttering a falsehood. More rude and ferocious than the tribes whose territories lie upon the shore of the sea, the Labdesséba and Ouadelim Arabs are also more confined and illiberal in their ideas, not only believing that they are the first nation in the world, but fancying that the sun rises only for them. Brisson relates, that some of them expressed this idea in unequivocal terms. 'Behold (said they) that luminary, which is unknown in thy country. During the night, thou art not enlightened, as we are, by that heavenly body, which regulates our days and our fasts. His children (the stars) point out to us the hours of prayer. You have neither trees nor camels, sheep, goats, nor dogs. Are your women similar to ours?' 'How long didst thou remain in the womb of thy mother (said another)?' 'As long (replied Brisson) as thou in that of thine.' 'Indeed (said a third, counting the fingers and toes of the Frenchman) he is made like us: he differs only in his colour and language.' 'Do you sow barley in your houses?' said the Arabs, alluding to the ships of the Europeans 'No (said Brisson), we sow our fields almost in the same season as you.' 'How! (cried several) do you inhabit the earth? we believed that you were born and lived upon the sea.' These Arabs, according to the Turkish proverb, believe that all the world is like their father's house: unacquainted with the manners of other nations, and unaccustomed to reflect upon the causes of national character, every variation from their own customs appears not only ridiculous, but monstrous; every difference of opinion not only absurd, but criminal. This ignorance of the Arabs, conjoined with their local and religious prejudices, enables us to account for the insulting treatment which Brisson and his companions received, without having recourse to inherent depravity of nature." That treatment was indeed shocking.

Brisson had surrendered himself, on his shipwreck, to Sidi Mahomet, a *Talbe* or priest of the tribe of Labdesseba. During the absence of the priest, the Labdesseba, who guarded the captives, were attacked and maltreated by a party of the Ouadelims, and during the battle which ensued, Brisson had almost lost his life. Instead of compassionating his forlorn situation, the women threw sand into his eyes, as they said, to dry his eye lids. The Arabs, into whose hands he had fallen, had only come down to the sea-coast to gather wild grain, three days before the shipwreck; and to preserve their booty, they immediately retreated to the interior part of the desart. A guide preceded the horde, to place at intervals small pyramids of stone, to direct their course, at a distance from every hostile tribe After passing some very high mountains, wholly covered with small greyish pebbles as sharp as flints, they descended into a sandy plain overspread with thorns and thistles. When Brisson was unable to walk, on account of the bleeding of his feet, he was mounted on a camel; the bristly hair and hard trot of which Ouadelim. soon excoriated him so much, that the blood run copiously down its flanks. By throwing heated stones into a wooden vessel, filled with barley meal, diluted with water procured on the sea-shore, preserved in a goat's skin, and mixed with pitch to prevent putrefaction, the Arabs prepared a kind of soup, which they kneaded with their hands, and ate unchewed. They roasted a goat in heated sand, ate its fat raw, and, after having devoured the flesh, gnawed the bones, and scraped them with their nails, threw them to Brisson and his companions, desiring them to eat quickly, and load the camels, that the journey might not be impeded. Proceeding eastward, they crossed a vast plain, covered with small stones white as snow, round and flat as a lentil, where not a single plant was produced. The earth beneath their feet resounded dull and hollow, and the small stones pricked them like sparks of fire. The reflection of the rays of the sun from the sand was scorching; the atmosphere was loaded with a red vapour, and the country appeared as if filled with flaming volcanoes. Neither birds nor insects could be seen in the air. The profound silence was frightful. If a gentle breeze ever arose, it produced extreme languor, chopping of the lips, burning heat of the skin, with small smarting pimples This plain was even shunned by wild beasts. After traversing this plain, they entered another, where the wind had thrown up in furrows the sand, which was of a reddish colour. On the tops of the furrows grew a few sweet-scented plants, which were devoured by the camels. On quitting this sandy plain, they entered a valley surrounded by mountains, where the soil was white and slimy, and where they found water of a noxious smell, covered with green moss, and soon after discovered a horde of the friendly tribe Roussye.

After another journey of sixteen days, they arrived at the tents of the Labdesseba horde, to which Sidi Mahomet belonged. The tents pitched among thick bushy trees, and the numerous flocks feeding along the sides of the hills, presented at a distance an aspect of happiness and pastoral simplicity. On approaching near, the trees of beautiful green foliage proved to be only old gummy stumps, almost void of branches, so encircled with thorns that their shade was inaccessible. The women approached, with loud cries and the most fawning servility, to welcome their tyrants, to throw stones at the Christians, and spit in their faces, while the children imitated the example of their mothers. Brisson, who endeavoured to ingratiate himself with his master's favourite, not only failed in this, but incurred her implacable resentment, through his irritability, which to the Arab women seemed extremely to resemble petulance. During his residence with Sidi Mahomet, the hardships he endured were almost incredible. With the excessive heat, the milk of the sheep, goats, and camels, diminished, and then the dogs fared better than the Christians, who were forced to subsist on wild herbs and raw snails. When the rains fell, and the least pressure made the water to spring up through the sandy soil, the Christians slept behind a bush, unsheltered, on the bare ground. Brisson and his master sometimes reasoned about religion; when the latter always answered the harangues of the former by declaring, that he preferred a bowl of churned milk to such

absurdities. Several of his companions perished, and were left by the Arabs to be devoured by the ravens, while in the struggles of death. One of them was supposed to be murdered by his master for milking his camels clandestinely. An application made by Brisson to the consul at Mogador, by a letter entrusted to a Jewish merchant, was frustrated through the negligence of the vice-consul; and the Labdesseba Arabs thought the journey too dangerous to be encountered for the ransom of their slaves. He was, however, at last relieved, through the humanity of his master's brother-in-law, who carried him to Morocco, where his ransom was paid by the Emperor, and whence he returned to France. For a fuller account of these two savage tribes, see *Saugnier's and Brisson's Narratives*; or a very pleasing *Historical and Philosophical Sketch of the Discoveries, &c. of the Europeans in Northern and Western Africa*, published 1790 by *Symington* Edinburgh, and *Vernor* and *Hood* London.

OXYGLYCUS CERASUS, the name given by the editor of Dalzel's History of Dahomy to a very singular fruit produced in that country, as well as in some other parts of Africa. It resembles a small olive in every respect but the colour; being of a dusky reddish hue, changing at the end next the stalk to a faint yellow. The pulp is firm, and almost insipid; the stone is hard like that of the olive. After having chewed one or more of such berries, and spit out or swallowed the pulp at pleasure, a glass of vinegar will taste, to the person trying the experiment, like sweet wine; a lime will seem to have the flavour of a very ripe China orange; and the same change is produced on other acids, the ordinary effects of which upon the palate is destroyed in a very unaccountable manner, without effervescence or any sensible motion. Indeed, the effect is very different from neutralization, arising from the mixture of acid and alkali; such combination producing a neutral saline liquor, whilst this miraculous berry seems to convert acids to sweets. Food or drink, not containing any acid, suffer no change by the previous use of this fruit; its effect upon acids continues, even after a meal, though in a much smaller degree. The natives use it to render palatable a kind of gruel called *guddoe*, which is made of bread after it becomes too stale for any other purpose. They describe it as the fruit of a large tree.

Plants six or seven inches high were raised from this fruit by Mr Dalzel, who tried to carry them from Angola to the botanic garden at St Vincent's; but they died on the passage. He preserved the berries in spirits, in syrup, and in a dry form; but they lost their singular quality in all those preparations. The plant is an evergreen, and the leaves in this infant state are like those of the olive.

OXY-MURIATIC ACID (See CHEMISTRY-*Index* in this *Suppl.*), is the principal agent in the new process of bleaching (see BLEACHING, *Suppl*); but, till very lately, at least, if not even at present, the bleachers were in the practice of adding some alkali to the acid, notwithstanding the strong objections which M. Bertholet made to that addition, and notwithstanding the proofs urged by Mr Rupp, that it increases the expence of bleaching about 40 *per cent*. The chief reason for persisting in a practice to which such objections were urged was, that the addition of the alkali deprives the liquor of its suffocating effects without destroying its bleaching powers. Mr Rupp, however, has contrived the following apparatus, in which may be safely used the pure oxy muriatic acid simply dissolved in water, which is at once its cheapest and best vehicle.

Figure 1. (Plate XLI.) is a section of the apparatus. It consists of an oblong deal cistern ABCD, made water-tight. A rib EE of ash or beech wood is firmly fixed to the middle of the bottom CD, being mortised into the ends of the cistern. This rib is provided with holes at FF, in which two perpendicular axes are to turn. The lid AB has a rim GG, which sinks and fits into the cistern. Two tubes HH are fixed into the lid, their centres being perpendicularly over the centres of the sockets FF when the lid is upon the cistern. At I, is a tube by which the liquor is introduced into the apparatus. As it is necessary that the space within the rim GG be air tight, its joints to the lid, and the joints of the tubes, must be very close; and, if necessary, secured with pitch. Two perpendicular axes KL, made of ash or beech wood, pass thro' the tubes HH, and rest in the sockets FF. A piece of strong canvas M is sewed very tight round the axis K, one end of it projecting from the axis. The other axis is provided with a similar piece of canvas. N are pieces of cloth rolled upon the axis L. Two plain pulleys OO are fixed to the axes, in order to prevent the cloth from slipping down. The shafts are turned by a moveable handle P. Q is a moveable pulley, round which passes the cord R. This cord, which is fastened on the opposite side of the lid (see fig. 2.), and passes over the small pulley S, produces friction by means of the weight T. By the spigot and fausset V, the liquor is let off when exhausted.

The dimensions of this apparatus are calculated for the purpose of bleaching twelve or fifteen pieces of $\frac{7}{8}$ calicoes, or any other stuffs of equal breadth and substance. When the goods are ready for bleaching, the axis L is placed on a frame in an horizontal position, and one of the pieces N being fastened to the canvas M by means of wooden skewers, in the manner represented in fig. 1. it is rolled upon the axis by turning it with the handle P. This operation must be performed by two persons; the one turning the axis and the other directing the piece, which must be rolled on very tight and very even. When the first piece the axis, the next piece is fastened to the end of it by skewers, and wound on in the same manner as the first. The same method is pursued till all the pieces are wound upon the axis. The end of the last piece is then fastened to the canvas of the axis K. Both axes are afterwards placed into the cistern, with their ends in the sockets FF, and the lid is put on the cistern by passing the axes through the tubes HH. The handle P is put upon the empty axis, and the pulley Q upon the axis on which the cloth is rolled, and the cord R, with the weight T, is put round it and over the pulley S. The use of the friction, produced by this weight, is to make the cloth wind tight upon the other axis. But as the effect of the weight will increase as one cylinder increases and the other lessens, Mr Rupp recommends that three or four weights be suspended on the cord, which may be taken off gradually as the person who works the machine may find it convenient. As the weights hang in open hooks, which are fastened to the

Oxy-Muriatic Acid.

the cord, it will be little or no trouble to put them on and to remove them.

Things being thus disposed, the bleaching liquor is to be transferred from the vessels in which it has been prepared into the apparatus, by a moveable tube passing through the tube I, and descending to the bottom of the cistern. This tube being connected with the vessels, by means of leaden or wooden pipes provided with cocks, hardly any vapours will escape in the transfer. When the apparatus is filled up to the line *a*, the moveable tube is to be withdrawn, and the tube I closed. As the liquor rises above the edge of the rim G, and above the tubes HH, it is evident that no evaporation can take place, except where the rim does not apply closely to the sides of the box; which will, however, form a very trifling surface if the carpenter's work be decently done. The cloth is now to be wound from the axis L upon the axis K, by turning this; and when this is accomplished, the handle P and pulley Q are to be changed, and the cloth is to be wound back upon the axis L. This operation is, of course, to be repeated as often as necessary. It is plain, that by this process of winding the cloth from one axis upon the other, every part of it is exposed, in the most complete manner, to the action of the liquor in which it is immersed. It will be necessary to turn, at first, very briskly, not only because the liquor is then the strongest, but also because it requires a number of revolutions, when the axis is bare, to move a certain length of cloth in a given time, though this may be performed by a single revolution when the axis is filled. Experience must teach how long the goods are to be worked; nor can any rule be given respecting the quantity and strength of the liquor, in order to bleach a certain number of pieces. An intelligent workman will soon attain a sufficient knowledge of these points. It is hardly necessary to observe, that, if the liquor should retain any strength after a set of pieces are bleached with it, it may again be employed for another set.

With a few alterations, this apparatus might be made applicable to the bleaching of yarn. If, for instance, the pulley O were removed from the end of the axis K, and fixed immediately under the tube H;—if it were perforated in all directions, and tapes or strings passed through the holes, skains of yarn might be tied to these tapes underneath the pulley, so as to hang down towards the bottom of the box. The apparatus being afterwards filled with bleaching liquor, and the axis turned, the motion would cause every thread to be acted upon by the liquor. Several axes might thus be turned in the same box, and being connected with each other by pulleys, they might all be worked by one person at the same time; and as all would turn the same way and with the same speed, the skains could not possibly entangle each other.

P.

Painting.

ENCAUSTIC PAINTING is an art of very high antiquity, which, after being lost for many ages, was restored, as is commonly believed, by the celebrated Count Caylus, whose method was greatly improved, first by Mr Josiah Colebrooke, and afterwards by Miss Greenland, who brought the rudiments of her knowledge from Italy (See ENCAUSTIC, *Encycl.*). In that country encaustic painting had employed the attention of various artists and men of learning, such as Requeno, Lorgna, and Astori, &c; but the best account of it that has fallen under our notice, is in that valuable miscellany called the *Philosophical Magazine*, taken from a work of Giov. Fabbroni, published at Rome in the year 1797.

According to this author, "the knowledge and use of encaustic painting is certainly older than the time of the Greeks and the Romans, to whom the learned Requeno seems to assign the exclusive possession of this art; because the Egyptians, who, with the Etruscans, were the parents of the greater part of the inventions known among mankind, and from whom the Greeks learned so much, were acquainted with and employed encaustic painting in the ancient ages of their greatness and splendour, as is proved by the valuable fragments of the bandages and coverings of some mummies which he had examined. No oil-painting (he says), of only two or three hundred years old, exhibits a white paint which has kept so well as that seen on these fragments; and this circumstance sufficiently proves the superiority of the encaustic method over the common oil-painting, which, notwithstanding the general opinion, cannot, he thinks, have been unknown to the ancients.

"It is impossible (says he) that in Egypt and Phoenicia, where so much use was made of flax, the oil procured in abundance from that plant should have been unknown. Those who have kept oil, or who have spilt any of it, whether nut or linseed oil, must have remarked that it possesses the property of soon drying by the effects of the atmosphere; and therefore it may be easily believed that mankind must soon have conceived the idea of employing it, particularly for ships, which, as Herodotus says, were painted with red ochre in the earliest periods, and adorned with figures and ornaments. The use of oil afforded painting a much simpler and easier method than that of wax; it must therefore have been first adopted, and the transition from oil to wax must be considered as a step towards bringing the art to perfection; because encaustic painting is not exposed to the irremediable inconveniences that arise in oil-painting, the value of which we extolled through ignorance, and praised as a new invention.

"Oil in general, and in particular drying oil which the painters use, has naturally a strong inclination to combine itself with the vital air or oxygen of the atmosphere, and by imbibing oxygen it becomes dry, and assumes the character of resin; but the colour then becomes darker, as is the case with transparent turpentine, which gradually becomes a black pitch.

"Accord-

Painting.

"According to the new and more accurate method of decomposing bodies, oil consists principally of hydrogen and carbon. By coming into contact with the atmosphere, and absorbing its oxygen and light, it undergoes a slow and imperceptible combustion, which is not essentially different from the speedy and violent one which it would undergo in the common mode of burning. It first passes, by imbibing oxygen, into the state of a more or less dark resin; loses gradually its essential hydrogen, which makes a new combination, and afterwards the oxygen itself which has attracted the carbon; and at length leaves behind a thin layer of actual carbon, which in the end becomes black in the course of time, and considerably obscures the oil painting. By a continuance of the before-mentioned slow combustion, the carbon itself, as it were, burns also: if it be strongly acted upon by the light, it attracts the oxygen of the atmosphere, and again brings forward the carbonic acid or fixed air, which gradually flies off. By this, which I may call the second degree of combustion, the painting must become dusty and friable, like crayon *painting*.

"Hence it appears (says our author) that one can hope only for a transient or deceitful effect from the refreshing of oil-paintings with oil; because the harmony of the tones, which the painter establishes as suited for the moment, does not proceed with equal steps, and cannot preserve itself in the like measure for the course of a few years, as each tint, as they say, ought to increase, or, to speak more properly, to burn in proportion to its antiquity. It thence follows, that mere washing may be prejudicial to an old painting; and that the method of refreshing paintings, as it is called, by daubing over the surface, from time to time, with new drying oil, is highly prejudicial and ill calculated for the intended purpose, since the oil when it becomes dry contracts in its whole surface, carries with it the paint under it, and occasions cracks in the painting. New oil of this kind gives occasion to mineral paints to be restored; but covers the picture with a new coat of resin, and then of carbon, which arises from the gradual combustion, and always causes more blackness, and the decay of the painting which one wishes to preserve.

"Wax, on the other hand, undergoes a change which is very different from that of drying oil. The wax, instead of becoming black by the contact of the atmosphere, increases in whiteness, and, according to its natural quality, is not decomposed in the air, and it does not strongly attract the oxygen of the calces or metallic ashes which are commonly used in painting. Moreover, the so called earths, which are in themselves white, and are never variable either by the presence or absence of oxygen, cannot be employed in oil-painting, because that fluid makes them almost transparent, and causes them to remain as it were without body, and not to produce the wished for effect. That beautiful white, which may be observed on the before mentioned Egyptian encaustic, is nothing else than a simple earth, and according to our author's chemical experiments, a chalk which is also unalterable."

That the ancients were once acquainted with the use of oil-painting, and neglected it on account of the great superiority of the encaustic method, our author thinks farther evident from the different accounts which we have of the ancient paintings. "Thus Petronius praises the fresh appearance which the valuable works of Zeuxis and Apelles had, even in his time; but Cicero, on the other hand, speaks of the painting, of the ancients having suffered from blackness. The former speaks of wax-painting, and the latter certainly alludes to paintings in oil. It is well known that paintings with wet chalks or water colours do not become black by age, and that this is the case also with encaustic. Of this any one may be convinced, not only by the expressions of the above quoted authors, but by one's own eyes on surveying the Egyptian fragment alluded to. Galland proves, on various grounds, that a painting was made with oil so early as the reign of Marcus Aurelius; and if no specimens of that period have reached us, this is perhaps to be ascribed to the frail and perishable nature of this species of painting."

Sign. Fabbroni, after some farther observations, calculated to prove that metallic oxyds or calces could not have been employed as pigments on such mummies as still retain their colours fresh, proceeds thus: "Those who are acquainted with the accuracy and certainty of the method not long since introduced into chemical operations, will be convinced, that in 24 grains of the encaustic painting, which I ventured to detach from the above mentioned Egyptian fragment, in order to subject it to examination, the mixture of an hundredth part of a foreign substance would have been discovered with the greatest certainty; that the resin of Requeno must undoubtedly have been perceptible to me, and that the alkali of Bachelier and Lorgna could not have escaped the counteracting medium. But in this Egyptian encaustic I found nothing except very pure wax, though I varied my analysis in every known method. I must therefore conclude, that modern learned writers, at least in respect to this Egyptian mode of painting, were as far from the truth as the accounts of ancient authors appear to me precise and satisfactory; and that the encaustum with which formerly the fore part of ships and the walls of houses and temples were painted, was something different from soap or resinous crayons.

"I am well aware that it will be asked, In what manner can wax at present be rendered sufficiently liquid for the strokes of the pencil, if it be not converted into powder or soap? This question, in my opinion, can be fully answered from the words of an ancient author, and, in the next place, by experience.

"Vitruvius in particular, book vii. chap. ix. expresses himself in the following clear manner:

'Those (says he) who wish to retain cinnabar on walls, cover it, when it has been well laid on and dried, with Punic wax diluted in a little oil (let this be well remarked); and after they have spread out the wax with a hair brush, they heat the wall by means of a brazier filled with burning coals (hence it is called encaustic painting), and then make it smooth and level by rubbing it with wax tapers and clean cloths, as is done when marble statues are covered with wax. The effect of this wax crust is, that the colour is not destroyed by the light of the sun or the moon (A).'

Ss 2 "It

(A) The reader will find the original of this passage, with a translation somewhat different, in the article ENCAUSTIC, *Encycl.*

"It here appears, that the Romans, who copied the Grecian process, which the latter borrowed from the Egyptians, mixed the wax with an oil to make it pliable under the brush; but no mastic, alkali, or honey, as has been ingeniously imagined, and which some have thought might be employed with success. The difficulty now will be confined to point out in what manner this oil was employed. It does not appear that they used those fat oils which are commonly called drying oils; because they could have employed these as we do, without the addition of wax, which, in such a case, would have been entirely superfluous. Fat oils which do not dry would not have been proper for that purpose, as they would have kept the wax continually in the state of a soft pomade or salve. Besides, my experiments (continues the author) would without doubt have shewn me the existence of any oily matter.

"With regard to essential or volatile oils, a knowledge of them is not allowed to the ancients, as the invention of distilling is not older than the eighth or ninth century, and therefore falls in with the period of Geber or Avicenna" Yet it is certain, that, in order to use wax in their encaustic painting, they must have combined it with an ethereal volatile oil, of which no traces should afterwards remain; because this was necessary for the solidity of the work, and because no oil was found in the fragment that was examined. But naphtha is such an oil, much lighter (says our author) than ether of vitriol itself. It is exceedingly volatile, and evaporates without leaving a trace of it behind. On this account it is used when signatures and manuscripts are to be copied; because the paper, which is moistened by it, and so rendered transparent, quickly becomes white and opaque as before by the complete evaporation of the naphtha. That the Assyrians, Chaldeans, and Persians, were well acquainted with the properties of naphtha is known to every scholar; and hence our author thinks it highly probable that it was used by those nations to render wax fit for painting. "It appears to me (says he) that the Greeks, as was the case with many other things, learned encaustic from the Egyptians, who probably derived it from the Assyrians or Chaldeans; and if so, we have discovered the real mixture used for ancient encaustic painting."

To put the matter, however, beyond a doubt, Sign. Fabbroni prepared, for an eminent Saxon painter, a solution of Venetian wax in highly purified naphtha, desiring him to mix up with it the colours necessary for a painting. The artist complied; and both he and our author were astonished, as well as all their friends, at the high tone which the colours assumed, and the agreeable lustre which the painting afterwards acquired when it had been rubbed over with a soft cloth. A similar solution of wax was made for another artist, in which the spirit of turpentine was used instead of naphtha with equal success. Our author therefore concludes, we think with reason, that if he has not discovered the real composition employed by the ancients in their encaustic paintings, he has at least approached much nearer to that discovery than any of his predecessors who have employed their learned labours in the same field of investigation.

PAINTINGS, or PICTURES, are often done upon objects from which, when they are valuable, it would be desirable to transfer them. Thus, a connoisseur in painting might naturally wish to transfer an old and valuable picture from the ceiling or walls of his room to stretched canvas; and such a man would consider himself as deeply indebted to the artist who should perform so arduous a task. This task has actually been performed by Mr *Robert Salmon* of Woburn, Bedfordshire, who was honoured by the *Society for the Encouragement of Arts, &c.* with the greater silver pallet, for communicating the method by which he accomplished it.

"The first thing (says Mr Salmon) to be attended to with respect to paintings, either on plastered walls or ceilings, or on boards, is, that the place in which they are be secure from wet or damp. If the paintings are on old walls in large buildings, or other places where this cannot be attained by art, then the summer season should be taken for the purpose, as the picture will rarely escape damage, if wet or damp gets at it while under the process. At the same time, care should be taken that the room, or other place, be not overheated; as that would produce equally bad effects.

"These precautions being taken, the next thing is to examine the surface of the painting. If there are any holes in the same, they must be carefully filled up with a paste or putty, made of glue and whiting: this, if the holes are large, should be twice or thrice done, so as entirely to fill them up, and leave the surface even and smooth; but if there are any bruised places, with paint still remaining on the surface of the bruised parts, then this stopping must not be applied, but the securing canvas, hereafter described, must be pressed down into these places. In the places that are stopped, there will of course appear blemishes when the picture is transferred; but the process is rendered much more certain and sure by being so done. Attention must next be paid to lay down any blisters, or places where the paint is leaving the ground: this is done by introducing, between the paint and the ground, some very strong paste of flour and water; and the surface of the blistered paint being damped with a wet sponge or brush, it may be pressed with the hand home to the ground, to which it will then adhere.

"All the unsound places being thus secured, care must be taken to clear the surface of any grease or dirt, as also of any particles of the paste that may happen to be left on it. The next thing is, to determine the size of the painting meant to be taken off: If it is on a plain surface, a board of the size of the picture must be procured, not less than an inch in thickness, and framed together with well seasoned wood, in small pannels, smooth and flush on one side. This done, a piece of fine open canvas must be provided, such as the finest sort used for hanging paper on; which canvas is to be somewhat larger than the picture, and so sewed together, and the seam so pressed, that it be perfectly smooth and even. This is what Mr Salmon calls the securing canvas; which, being so prepared, is to be stuck on the surface of the picture with a paste made of strong beer, boiled till it is half reduced, and then mixed with a sufficient quantity of flour to give it a very strong consistence. To large pictures on walls or ceilings, the canvas must for some time be pressed, and rubbed with the hand as smooth as possible, working it from the middle to the outside, so as to make it tolerably tight; observing, as it dries, to press it, with the hand or a cloth, into any hollow or bruised places, so that

Paintings. that it may adhere to every part of the painting: this done, it is left to dry; which it will generally do in a day or two. When dry, a fecond canvafs, of a ftronger and clofer fort, and of the fame fize as the other, is in like manner to be attached on the top of the firft. This laft will want very little attention, as it will readily adhere to the firft; and, being dry, attention muft be paid to take off any fmall knots or unevennefs that may be upon the furface of it; which done, the whole fhould be again covered with a thin pafte of fize and whiting; which is to be pumiced over when dry, fo as to make the whole perfectly fmooth and even.

"The painting being thus fecured, the board, already prepared to the fize of the picture, is to be put with the fmooth fide againft the furface thereof, fo as exactly to cover as much as is intended to be transferred. The edges of the canvas, which, as before directed, is to be larger than the painting, are then to be pulled tight over, and clofely nailed to the edge of the board. If the painting is large, and either on a ceiling or wall, the board muft, by proper fupports, be firmly fixed againft it, fo that it can readily be lowered down when the plafter and painting are detached.

"The canvas and board being fixed, the painting is to be freed from the wall or ceiling, together with a certain portion of the plaftering: this, with proper care and attention, may be readily done. If on a ceiling, the firft thing is to make fome holes through the plaftering, round the outfide of the board and painting; and, with a fmall faw, to faw the plaftering from one hole to another, till the whole is difunited from the other parts of the ceiling: this done, the workman muft get at the upper fide of the ceiling, where he muft free the plaftering from the laths, by breaking off the keys thereof, and with a chifel cut out the laths; whereby the plaftering, together with the picture, will be left refting on the board and fupports.

"If the painting is on a brick or ftone wall, the wall muft be cut away at top, and down the fides of the painting; and then, by means of chifels or faws in wooden handles, of different lengths, the wall muft be cut away quite behind the painting; leaving the fame, together with the plaftering, refting on the board. This operation may fometimes be done with a faw; or, if the wall be not thick, nor the other fide of much confequence, the bricks or ftones may be taken out from that fide, leaving the plaftering and painting as before. This laft method (fays the author) I have not practifed: the other, of cutting away fome part of the wall, I have, and fee no difficulty, or very great labour, in the operation; but that, of courfe, muft be various, according to the texture of the wall and mortar.

"If the paintings are on curved furfaces, fuch as the coves of ceilings, then the only difference of operation is, that fome ribs of wood muft be cut out, and boarded fmooth to the curve of the furface of the painting, and then fixed up thereto, in place of the before defcribed bearing-board; the painting is then to be freed, and left with the plaftering, refting on the bearers.

"For paintings on wainfcot or boards, the fame fecuring and procefs is to be exactly followed; only that, as the wainfcot or board can always be cut to the fize wanted, and laid horizontal, the fecuring canvas is to be ftretched thereon, and turned over the edges of the fame, till it is dry; after which, the edges are again to be turned up, and nailed to the board, in the fame manner as with refpect to paintings from walls.

"Having, as before defcribed, in any of the aforementioned cafes, freed the paintings from their original places, you have got them fecured to two thickneffes of canvas, with their furfaces on the board prepared for that purpofe; this being the cafe, they can readily be removed to any room or fhop, to be finifhed as follows: Having carried the painting into the fhop or room, which fhould be moderately warm and dry, but by no means overheated, lay the board on a bench or treffels, fo that the back of the picture be uppermoft: the plaftering or wood, as may happen, is then to be cleared away, leaving nothing but the body of paint, which will be firmly attached to the fecuring-canvafs. To perform this, a large rafp, a narrow plane, and chifels, will be requifite. This operation, though difficult to be defcribed, would foon be learned by any one who fhould make the attempt; nor is it very tedious; and fo performed, the picture is ready to be attached to its new canvas, as follows.

"The painting being cleared, and lying on the board, the back thereof is to be painted three or four times over fucceffively, with any good ftrong-bodied paint, leaving one coat to dry before another comes on: a day or two between each will generally be found fufficient. Each of thefe coats, and particularly the firft, fhould be laid on with great care, taking but a fmall quantity in the brufh at a time, and laying it very thin. This precaution is neceffary, to prevent any of the oil or paint from paffing through any fmall cracks or holes in the furface of the picture; as fuch oil or paint would run into the pafte, and fo attach the fecuring canvas to the picture, as to prevent its being afterwards got off. If any fuch holes or cracks are obferved, they fhould be ftopped up with the glue and whiting pafte, and the painting then repeated, till a complete coat is formed on the back of the picture. It is then ready for attaching to its canvas, which is done by fpreading all over the picture a pafte made of copal varnifh, mixed with ftiff white lead, and a fmall quantity of any other old fat paint; all which being fpread equally over with a pallet knife, fuch a canvas as the firft fecuring canvas is laid thereon, and ftrained and nailed round the edges of the board; in which ftate it is left till it becomes tolerably dry: then a fecond canvas, of a ftronger fort, muft be in like manner attached on the firft, and left till it is perfectly dry and hard. This generally takes about two months; and the longer the painting is left, the more fecurely it will be attached to its canvas, and lefs liable to crack or fly therefrom. When fufficiently dry, all the four canvaffes are to be unnailed from the board, and the edges turned up the reverfe way, and nailed to a proper ftretching frame. This is done by unnailing from the board a part on each fide at a time, and immediately nailing it to the ftretching frame, fo as never to leave the canvas to crack or partially ftretch, which would damage the picture. In this manner, by degrees, the cloths are entirely detached from the board, and firmly fixed on the ftretching frame. The fuperfluous canvas, left larger than the frame, may then be cut off, and the wedges put in the frame, and moderately tightened up. There remains then only to clear the furface of the painting from the fecuring canvafs; which is done by repeatedly wafhing the furface

with

with a sponge and moderately warm water. In doing this, no violence or force must be used; and, by frequent and gentle washings, the paste will all be worked out with the sponge. The edges of the outer canvas are then to be cut round, and stripped off: the other, next the surface of the picture, is to be served in like manner; which done, nothing remains but to take the paste clean off, and repair any defects: the picture will then be as strong as if painted on the canvas.

"For taking pictures off walls, without taking the walls down, or cutting away more thereof than the plastering, the following process is proposed:

"The surface of the picture is to be first secured, in the manner before described; but instead of the plain board, a bearer should be prepared with a convex surface, composed of ribs, boarded over, so as to form part of a cylinder, of not less than five feet radius, and as long as the height of the picture. This bearer being prepared, in order to apply it, a floor or platform should be erected, and placed horizontally, with its surface level, and its edge immediately in contact with the bottom of the picture meant to be transferred. The use of this platform is for the above described bearer to rest and move upon; which bearer should be set on its end, with one edge in contact with the wall, at one side of the picture; consequently the other edge will be at some distance from the wall, according to the size of the picture and convexity of the bearer. Being thus placed, the superfluous edge of the securing-canvas should be turned over, and nailed to that edge of the bearer that is next the wall: This done, the operation of cutting away the plastering should be begun; which may be done with the corner and end of a short saw; sawing between the brick-work and plastering, and leaving the thickness, or part of the thickness, of the plastering on the painting fastened to the bearer. When this edge of the picture is freed, the whole height, for nine or ten inches under the edge of the bearer that is furthest from the wall, must then be gently forced nearer; consequently the other edge, together with the painting and plaster that is freed, will leave the wall, and give an opportunity of introducing the saw behind, and cutting away the same to a certain distance farther under; and, by repeating this, the whole of the picture will at length be freed, and left on the bearer. Each time the bearer is removed, and, as it were, rolled on the vertical surface of the wall, care must be taken to turn and nail the securing-canvas on the top and bottom edges of the bearer, so as to secure the freed plastering and picture from moving about; and, lastly, before the bearer and plastering be moved, to nail the other edge of the picture in the same way, which will secure the whole to the bearer. This done, the picture and bearer are at liberty to be moved to a proper place, in order to be freed from the remaining plaster. The edges may then be unnailed; the painting and canvas slipped from this bearer on to a plain board; and the new canvas may be then put on; which is to remain till dry, as in other cases.

"It may appear, that the bending of the canvas and plastering to the convex bearer will crack the plaster, and damage the painting; but, from experience (says Mr Salmon) I have observed, that, to a curve of such or even less radius, plastering will bend, without any visible crack, even on the exterior part thereof; and that part next the bearer, not having occasion, in bending, to extend its parts, will consequently be much less liable to be disturbed by such bending."

In clearing the wood from the paintings, our author never made use of aquatortis, or any other liquid; the use of which he conceives would be very tedious, and attended with danger, lest it should get through the paint, and wet or damp the paste by which the securing canvass is fixed. In working off the wood, he generally made use of such planes as by the joiners are called the *levelled rabbit plane*, and *small rounds*. By the corners of the former, and proper handling of the latter, the wood is cleared off without force or violence: even the smallest particles may, in general, be got off; although in some paintings, and in particular parts of others, he has met with places on which he thought it best to leave some particles, or fine splinters, of wood, but nothing more. Rasps, and sometimes a fine chisel, are useful, to clear off such parts as may be in hollow places, or where particles of wood are left, as above. The time required will be various, according to the manner in which the painting was originally done; some being painted on boards previously prepared with a water colour; others immediately painted with oil on the wood. This last sort is by much the most difficult; the other is more easy, as the previous preparation prevents the wood from imbibing the oil, and consequently admits it to be more easily separated.

PALILICUM, the same as Aldebaran, a fixed star of the first magnitude, in the eye of the bull, or sign Taurus.

PALLIFICATION, or PILING, in architecture, denotes the piling of the ground-work, or the strengthening it with piles, or timber driven into the ground; which is practised when buildings are erected upon a moist or marshy soil.

PALM, an ancient long measure, taken from the extent of the hand. See PALMUS, *Encycl.*

PALMÆ, palms. See *Encyclopædia*. The subject is introduced here to notice a kind of palm, the product of North America, of which we have the following account by Dr Barton.

"There grows upon the river Mobile a species of palm, which is but little known to naturalists, but which promises to be an important article of food to man. It has no stalk or stem above ground. The leaves spread regularly all round, and when fully expanded are flabelliform. In the centre of these leaves is produced the receptacle of the fruit, which is of the form and size of a common sugar-loaf. This receptacle consists of a vast number of drupes, or berries, of the size and shape of common plums: each is covered with a fibrous, farinaceous, pulpy coating, of considerable thickness. This substance is said to resemble manna in texture, colour, and taste; or, perhaps, it still more resembles moist brown sugar, with particles of loaf sugar mixed with it. It is a most delicious and nourishing food, and is diligently sought after in the places where it grows. Upon first tasting it, it is somewhat bitter and pungent.

PANORAMA, a word derived from παν and ὁραω; and therefore employed of late to denote a painting, whether in oil or water colours, which represents an entire view of any country, city, or other natural objects, as they appear to a person standing in any situation, and turning quite round. To produce this effect, the

the painter or drawer must fix his station, and delineate correctly and connectedly every object which presents itself to his view as he turns round, concluding his drawing by a connection with where he began. He must observe the lights and shadows, how they fall, and perfect his piece to the best of his abilities. There must be a circular building or framing erected, on which this drawing or painting may be performed; or the same may be done on canvas, or other materials, and fixed or suspended on the same building or framing, to answer the purpose complete It must be lighted entirely from the top, either by a glazed dome, or otherwise as the artist may think proper. There must be an inclosure within the said circular building or framing, which shall prevent an observer going too near the drawing or painting, so as it may, from all parts it can be viewed, have its proper effect. This inclosure may represent a room, or platform, or any other situation, and may be of any form thought most convenient; but the circular form is particularly recommended. Of whatever extent this inside inclosure may be, there must be over it (supported from the bottom, or suspended from the top) a shade or roof; which, in all directions, should project so far beyond this inclosure, as to prevent an observer from seeing above the drawing or painting when looking up; and there must be without this inclosure another interception, to represent a wall, paling, or other interception, as the natural objects represented, or fancy, may direct, so as effectually to prevent the observer from seeing below the bottom of the drawing or painting; by means of which interception, nothing can be seen on the outer circle but the drawing or painting intended to represent nature. The entrance to the inner inclosure must be from below, a proper building or framing being erected for that purpose, so that no door or other interruption may disturb the circle on which the view is to be represented. And there should be, below the painting or drawing, proper ventilators fixed, so as to render a current circulation of air through the whole; and the inner inclosure may be elevated, at the will of an artist, so as to make observers, on whatever situation he may wish they should imagine themselves, feel as if really on the very spot.

PAPER is an article of such importance, and at present * of so enormous a price, that no improvement in its manufacture should pass unnoticed in a work of this nature. The discovery made in France by M. Bertholet of the efficacy of oxy-muriatic acid in expediting the process of BLEACHING (see that article in this *Suppl.*), has contributed essentially to facilitate the manufactures, not only of cotton and linen cloths, but also of paper, of which it has even increased the materials. Formerly writing paper could be made of *unprinted* linen alone; but by means of the process of M. Bertholet even printed linen may be made into the finest and whitest paper. In the year 1795 a patent was granted to Mr Elias Carpenter of Bermondsay, Surrey, for a method of bleaching paper of such materials in the *water-leaf* or *sheet*, and sizing it without drying.

* 1800.

In the preparation of the pulp, the coarser rags are to be macerated for two or three days in a caustic alkaline ley, and wrought into sheets of paper in the usual way; a strong wooden box or trough is then to be procured, of a size proportioned to that of the paper, lined on the inside with white paint, and furnished with several stages of cross bars of glass: the bottom of the box is to be covered with a stratum about one inch deep of caustic ley, and the paper laid by quarter reams, or less, across the glass bar. A hole must be made in the box to admit the beak of an earthen ware retort, into which must be put manganese and sea salt, in powder, sulphuric acid, and an equal quantity of water impregnated with the steams of burning sulphur (sulphureous acid). The cover of the box is to be made air-tight by luting or slips of paper dipped in paste. The apparatus being thus prepared, the belly of the retort is to be plunged in water, kept boiling, and in a short time the oxy muriatic gas will be driven into the box, will penetrate the paper, and render it of a dazzling whiteness, while the alkaline ley at the bottom will, by gradually absorbing it, prevent its becoming so concentrated as to destroy or injure the texture of the paper. From three to four pounds of sulphuric acid will suffice for one hundred weight of paper, and the operation will be completed in about eight hours. The sheets as they are taken out of the box are to be sized with the following mixture:

To 1 cwt of clippings of skin add 14 lb. of alum, 7 of calcined vitriol, and 1 lb. of gum arabic, with a sufficient quantity of water to size 50 reams of fools cap.

The same method will serve equally well to clean engravings or printing; for though the oxy-muriatic acid discharges all stains, dirt, &c yet it is incapable of acting on printers ink.

This, however, is not the only improvement in the manufacture of paper derived from modern chemistry. In Crell's *Chemical Annals* for the year 1797, we have an account of some curious experiments made by M L. Brugnatelli, with the view of rendering

PAPER incombustible, and the writing on it, of course, indestructible by fire. Of all the substances which he tried, he found the liquor of flints the proper to secure paper from destruction by fire. He dipped a sheet of paper several times in the above liquor fresh made, or daubed it several times over the whole paper with a hair brush, and dried it in the sun or in an oven. Paper prepared in this manner lost some of its softness, became a little rougher than before, and acquired a lixivious caustic taste In other respects it was not different from common white paper When this paper was laid upon glowing coals, it did not burn like common paper, but became red, and was converted to a coal, which however did not fall into ashes like the coal of common paper, so that it might therefore be considered as petrified paper. This coal, however, is exceedingly friable; for when it is taken between the fingers, or pressed together in any manner whatever, it drops to pieces. Still the discovery must be a valuable one, if there be any kind of ink of such a nature as that the characters written with it continue visible on this coal. Such an ink M. Brugnatelli made by combining dissolved nitrite of zinc with common ink; and found, that the colour of this mixture, though it appeared somewhat pale on common paper, became so dark on prepared paper, that words written with it appeared more conspicuous than words written with common ink. When the paper was burnt, or reduced to a coal, those characters were so visible, in a clear *white* colour on a *dark* ground, that they could be read with as much ease as characters written with the best ink on white

white paper. If the ingenious author succeed in his attempts to discover a method of rendering his prepared paper less friable when burnt, his discovery will be one of the most important of the present age.

PARABOLIC CONOID, is a solid generated by the rotation of a parabola about its axis. This solid is equal to half its circumscribed cylinder; and therefore if the base be multiplied by the height, half the product will be the solid content.

Parabolic Pyramidoid, is a solid figure, thus named by Dr Wallis from its genesis or formation, which is thus: Let all the squares of the ordinates of a parabola be conceived to be so placed, that the axis shall pass perpendicularly through all their centres; then the aggregate of all these planes will form the parabolic pyramidoid. This figure is equal to half its circumscribed parallelopipedon. And therefore the solid content is found by multiplying the base by the altitude, and taking half the product; or the one of these by half the other.

Parabolic Space, is the space or area included by the curve line and base or double ordinate of the parabola.

Parabolic Spindle, is a solid figure conceived to be formed by the rotation of a parabola about its base or double ordinate.

Parabolic Spiral, is a curve arising from the supposition that the common or Apollonian parabola is bent or twisted till the axis come into the periphery of a circle, the ordinates still retaining their places and perpendicular positions with respect to the circle, all these lines still remaining in the same place. This figure is sometimes called the *Helicoid parabola*.

PARABOLOIDES, parabolas of the higher orders. The equation for all curves of this kind being $a^{m-n} x^n = y^m$, the proportion of the area of any one to the complement of it to the circumscribing parallelogram, will be as *m* to *n*.

PARACENTRIC MOTION, denotes the space by which a revolving planet approaches nearer to, or recedes farther from, the sun, or centre of attraction.

Paracentric Solicitation of Gravity, is the same as the vis centripeta.

PARACHUTE, a kind of large and strong umbrella, contrived to break a person's fall from an air-balloon, should any accident happen to the balloon at a high elevation. This contrivance was first thought of by Blanchard, who at different times, by means of the parachute, let fall from his balloon dogs and other animals. He ventured even to descend in this manner himself; but, whether from the bad construction of his parachute, or from falling among trees, he had the misfortune to break one of his legs. Citizen Garnerin, as he chooses to be called, was more successful. On the 21st of October 1797, he ascended from the garden de Mausseux at half past five in the evening; between the balloon and the car, in which he sat, was placed the parachute, half opened, and forming a kind of tent over the aërial traveller; and when the whole apparatus was at a considerable height, he separated the parachute and car from the balloon. The parachute unfolding itself, was, by his weight and that of the car, drawn of course towards the earth. Its fall was at first slow and vertical; but soon afterwards it exhibited a kind of balancing or vibration, and a rotation gradually increasing, which might be compared with that of a leaf falling from a tree. The aëronaut, however, reached the ground unhurt.

This parachute was of cloth, and its diameter, when unfolded, about twenty-five feet. To use such instruments with success, it is necessary that the car be suspended at a considerable distance from the parachute, so as that the centre of gravity of the whole shall be vertically below the centre of resistance made by the air to the descent of the parachute; for if the car be otherwise placed, it is evident that the parachute will incline to one side, descend obliquely, oscillate, and the smallest irregularity in its figure will cause it to turn round its vertical axis.

PARAGUATAN, a kind of wood which grows in Guiana, and promises to be of great utility as a dye stuff. We have seen no botanical description of the tree; but from the report made to the Council of Trade and Mines, by D. Dominique Garcia Fernandez, inspector of coinage, we learn that its bark, boiled in water, affords a coloured extract which resists the agency of acids for a longer time than brazil or logwood; that the colour may be revived by means of alkalies, after it has been destroyed by combination with acids; that vinegar, lemon juice, and tartar, render this colour more brilliant, while they entirely destroy the colours of brazil and logwood; that the fecula of the bark of paraguatan fixes and attaches itself to wool, cotton, and silk; and that the colour is brighter on silk than on wool, and brighter on wool than on cotton. The same fecula dried is afterwards soluble in alcohol, to which it communicates a tinge similar to that afforded by cochineal; but it must be confessed, that the colour obtained from paraguatan has not the force of that of cochineal, though it is superior to those of madder, brazil wood, and logwood. From these facts D. Fernandez considers the paraguatan as one of the most valuable productions which America furnishes to Spain.

PARALLAX (see *Encycl.*) is used, not only in astronomy, but also in levelling, for the angle contained between the line of true level, and that of apparent level. And, in other branches of science, for the difference between the true and apparent places.

PARALLEL RULER, is a mathematical instrument, consisting of two equal rulers, either of wood or metal, connected together by two slender cross bars or blades of equal length, moveable about the points of junction with the rulers. There are other forms of the instrument; some, for instance, having the two blades crossing in the middle, and fixed only at one end of them, the other two ends sliding in grooves along the two rulers, &c.

The use of this instrument is obvious. For the edge of one of the rulers being applied to any line, the other opened to any extent will be always parallel to the former; and consequently any parallels to this may be drawn by the edge of the ruler, opened to any extent.

PARALLELS, or PLACES OF ARMS, in a siege, are deep trenches, 15 or 18 feet wide, joining the several attacks together; and serving to place the guard of the trenches in, to be at hand to support the workmen when attacked. There are usually three in an attack: the first is about 600 yards from the covert-way, the second between 3 and 400, and the third near or on the

Parallelism — the glacis. It is said they were first invented or used by Vauban.

Paramaribo — PARALLELISM OF THE EARTH'S AXIS, is that invariable situation of the axis, in the progress of the earth thro' the annual orbit, by which it always keeps parallel to itself; so that if a line be drawn parallel to its axis, while in any one position, the axis, in all other positions or parts of the orbit, will always be parallel to the same line.

PARAMETER, a certain constant right line in each of the three conic sections; otherwise called also *latus rectum*.

PARAMARIBO, the capital of the Dutch settlement at Surinam, is situated on the right side of the beautiful river Surinam, at about 16 or 18 miles distance from its mouth. It is built upon a kind of gravelly rock, which is level with the rest of the country, in the form of an oblong square; its length is about a mile and a half, and its breadth about half as much. All the streets, which are perfectly straight, are lined with orange, shaddock, tamarind, and lemon trees, which appear in everlasting bloom; while, at the same time, their branches are weighed down with the richest clusters of odoriferous fruit. Neither stone nor brick is made use of here for pavement; the whole being one continued gravel, not inferior to the finest garden walks in England, and strewed on the surface with sea shells. The houses, which are mostly of two and some of three stories high, are all built of fine timber, a very few excepted; most of the foundations are of brick, and they are roofed with thin split boards, called *shingles*, instead of slates or tiles. Windows are very seldom seen in this country, glass being inconvenient on account of the heat; instead of which they use gauze frames: some have only the shutters, which are kept open from six o'clock in the morning until six at night. As for chimneys, there are none in the colony; no fires being lighted except in the kitchens, which are always built at some distance from the dwelling house, where the victuals are dressed upon the floor, and the smoke let out by a hole made in the roof: these timber houses are, however, very dear in Surinam, one of them having cost above L. 15,000 sterling. There is no spring water to be met with in Paramaribo; most houses have wells dug in the rock, which afford but a brackish kind of beverage, only used for the negroes, cattle, &c. and the Europeans have reservoirs or cisterns, in which they preserve rain-water for their own consumption; those of nicer taste let it first drop through a filtering-stone into large jars or earthen pots, made by the native Indians on purpose, which they barter at Paramaribo for other commodities. The inhabitants of this country, of every denomination, sleep in hammocks, the negro slaves excepted, who mostly lie on the ground: the hammocks used by those in superior stations are made of cotton, ornamented with rich fringe; these are also made by the Indians, and sometimes worth above twenty guineas; neither bedding nor covering is necessary, except an awning to keep off the musquitoes. Some people indeed lie on bedsteads; in that case they are surrounded, instead of curtains, with gauze pavilions, which admit the air freely, and at the same time keep off the smallest insect. The houses in general at Paramaribo are elegantly furnished with paintings, gilding, crystal chandeliers, china jars, &c.; the rooms are never papered or plastered, but beautifully wainscotted with cedar, and Brazil, and mahogany wood.

The number of buildings in Paramaribo is computed at about 1400, of which the principal is the governor's palace, whence there is a private passage through the garden which communicates with Fort Zelandia. This house, and that of the commandant, which has lately been burnt, were the only brick buildings in the colony. The town-hall is an elegant new building, and covered with tiles; here the different courts are held, and underneath are the prisons for European delinquents, the military excepted, who are confined in the citadel of Fort Zelandia. The Protestant church, where divine worship is performed both in French and Low Dutch, has a small spire with a clock; besides which there is a Lutheran chapel, and two elegant Jewish synagogues, one German the other Portuguese. Here is also a large hospital for the garrison, and this mansion is never empty. The military stores are kept in the fortress, where the society soldiers are also lodged in barracks, with proper apartments for some officers. The town of Paramaribo has a noble road for shipping, the river before the town being above a mile in breadth, and containing sometimes above 100 vessels of burden, moored within a pistol-shot of the shore. Before Holland became a province of France, and thereby lost her trade, there were seldom fewer than 80 ships at Paramaribo, loading coffee, sugar, cocao, cotton, and indigo, for the mother country, including also the Guinea-men that bring slaves from Africa, and the North American and Leeward Island vessels, which bring flour, beef, pork, spirits, herrings, and mackarel salted, spermaceti candles, horses, and lumber; for which they receive chiefly molasses to be distilled into rum. This town is not fortified, but is bounded by the river on the south east; by a large savannah on the west; by an impenetrable wood on the north east; and is protected by Fort Zelandia on the east. This citadel is only separated from the town by a large esplanade, where the troops parade occasionally. The fort is a regular pentagon, with one gate fronting Paramaribo, and two bastions which command the river; it is very small but strong, being made of rock or hewn stone, surrounded by a broad fosse well supplied with water, besides some outworks. On the east side, fronting the river, is a battery of 21 pieces of cannon. On one of the bastions is a bell, which is struck with a hammer by the centinel, who is directed by an hour-glass. On the other is planted a large ensign-staff, upon which a flag is hoisted upon the approach of ships of war, or on public rejoicing days. The walls are six feet thick, with embrasures, but no parapet.

Paramaribo is a very lively place, the streets being generally crowded with planters, sailors, soldiers, Jews, Indians, and Negroes, while the river is covered with canoes, barges, &c. constantly passing and repassing like the wherries on the Thames, often accompanied with bands of music; the shipping also in the road adorned with their different flags, guns firing, &c. not to mention the many groupes of boys and girls playing in the water, altogether form a pleasing appearance; and such gaiety and variety of objects serve, in some measure, to compensate for the many inconveniences of the climate. Their carriages and dress are truly magnificent; silk, embroidery, Genoa velvets, diamonds, gold and silver

Paramaribo, Paris. Paris.

lace, being daily worn, and even the masters of trading ships appear with buttons and buckles of solid gold. They are equally expensive at their tables, where every thing that can be called delicate is produced at any price, and served up in plate and china of the newest fashion, and most exquisite workmanship. But nothing displays the luxury of the inhabitants of Surinam more than the number of slaves by whom they are attended, often twenty or thirty in one family. White servants are seldom to be met with in this colony.

The current money are stamped cards of different value, from five shillings to fifty pounds: gold and silver is so scarce, that the exchange premium for specie is often above 10 *per cent.* A base Dantzic coin called a *bit*, value something less than sixpence, is also current in Surinam. English and Portuguese coin are sometimes met with, but mostly used as ornaments by the Mulatto, Samboe, Quaderoon, and Negro girls. The Negro slaves never receive any paper money; for as they cannot read, they do not understand its value; besides, in their hands it would be liable to many accidents, from fire or children, and particularly from the rats, when it becomes a little greasy.

This town is well supplied with provisions, *viz.* butchers meat, fowls, fish, and venison. Vegetables in particular the country abounds with; besides the luxuries peculiar to this climate, they import whatever Europe, Africa, and Asia can afford. Provisions, however, are excessively dear in general, especially those imported, which are mostly sold by the Jews and masters of ships. The first enjoy extraordinary privileges in this colony; the latter erect temporary warehouses for the purpose of trade, during the time their ships are loading with the productions of the climate. Wheat flour is sold from four-pence to one shilling per pound; butter, two shillings; butcher's meat never under one shilling, and often at one shilling and sixpence; ducks and fowls from three to four shillings a couple. A single turkey has sometimes cost one guinea and a half; eggs are sold at the rate of five, and European potatoes twelve, for sixpence. Wine three shillings a bottle. Jamaica rum a crown a gallon. Fish and vegetables are cheap, and fruit almost for nothing.

PARIS (Francis), a man more famous after his death than during his life, by the miracles which were said to be performed at his tomb. He is generally known by the name of Abbé Paris; and his pretended miracles, with others of like manufacture, have furnished deistical writers, and Mr Hume in particular, with a kind of argument against the reality of the miracles of which we have an account in the Gospel. It is merely that we may state his pretensions fairly, that we have introduced him to the notice of our readers; for in every other respect he is wholly unworthy of their regard. He was the son of a counsellor in Parliament, and had the prospect, if he had chosen it, of succeeding to his father's appointment; but he chose rather to become an ecclesiastic, and he became a very zealous one. He gave up all his possessions to his brother, refused preferment intended for him by the cardinal de Noailles, devoted himself entirely to retirement, and made stockings for his own support, and for the assistance of the poor. He died, perhaps in consequence of his rigorous mode of life, May 1. 1727, at the age of only 37. His brother raised a monument to him in the small churchyard of St Medard, to which the poor and the pious soon began to flock; and after a time it was reported, that, in consequence of their prayers at that tomb, some sick persons had received cures. As Paris had been a rigorous Jansenist, this was a fine opportunity for that sect to gain credit to their cause; the miracles were therefore multiplied, and a variety of persons affected the most singular convulsions.

The minds of the people becoming inflamed by these extravagancies, the court found it necessary to shut up the churchyard, which was done on the 27th of January 1732. On this occasion, some profane wit wrote upon the wall of the place,

> DE PAR LE ROY, defense a Dieu,
> De faire miracles en ce lieu.

The convulsions were continued, for a little while, in private houses, but by degrees the matter subsided, and the Abbé Paris was forgotten.

The distinction between miracles exhibited to serve a party, and attested only by those who are zealous in its support, and miracles performed in the sight of unbelievers, who, in spite of their deep-rooted prejudices, were converted by them, is too striking to be overlooked by any, but those who are desirous of drawing a false and impious parallel; yet has Mr Hume dared to represent the miracles performed at the tomb of this saint as outvying in number, nature, and evidence, the miracles of Christ and his apostles—with what truth, the following observations will shew:

1st, It was often objected by the enemies of the saint, and the objection was never confuted by his friends, that the *prostrations* at his sepulchre, like animal magnetism more lately, *produced* more diseases than they *cured*. Such, surely, was not the nature of our Saviour's miracles.

2dly, Though the crowds of sick and infirm persons who flocked to the tomb for relief were, by all accounts, innumerable; yet all the cures, of which the zealous historian of the Miracles could procure vouchers, amounted only to NINE! Now, were thousands, and ten thousands of diseased persons to apply to some circumforaneous quack, in full assurance of his extraordinary abilities and skill in physic, could it surprise any person, if the distempers of *eight* or *nine* of them should take a favourable turn while they were under a course of his useless medicines?

3dly, We do not read that of those nine who were cured by the dead Abbé, the greater part were Jesuits and enemies to the Jansenists; whereas the greater part of our Saviour's miracles were performed upon unconverted Jews, and one of them upon the servant of the high priest, who was thirsting for his blood.

4thly, The cures reported to have been performed at the grave of Paris were all such as might have been accomplished by natural means. Thus, a Spaniard who had lost one eye, and was distressed with an inflammation in the other, had the inflamed eye gradually cured, but not the lost eye restored. Another person having pricked his eye with an awl, lost the sight of it in consequence of the aqueous humour dropping out; but his sight was restored *whilst* he was paying his devotions to the Abbé—and so it would have been while he was cursing the Abbé, had he continued his execrations for a sufficient length of time.

5thly,

Paris, Parkhurst.

5*thly*, None of the cures said to have been performed were *instantaneous*. *All* the worshippers at the tomb persisted for *days*, several of them for *weeks*, and some for *months*, daily imploring the intercession of the Abbé *before* they received relief from their complaints.

6*thly*, Most of the devotees had been using *medicines* before they applied to the saint, and continued to use them *during the whole time* of their application; whilst it is confessed that the distempers of others had *abated* before they determined to solicit his help.

7*thly*, Some of the cures attested were *incomplete*, and only of a temporary duration. Thus, the Spaniard was relieved only from the most inconsiderable part of his complaint, and that too but for a very short period; for soon after his return home he relapsed into his former malady, as was fully attested by certificates and letters from Madrid. All this has been completely proved by the Archbishop of Sens; who in his *Pastoral Instruction*, published at the time the miracles were making a noise, has,

8*thly*, Clearly detected the deceit and little artifices by which those pretended miracles were so long supported. To that work we refer our readers; requesting them, after they have read it, to compare the evidence for the miracles of Paris with the evidence which in the article MIRACLE (*Encycl.*) we have stated for the reality of the Gospel miracles, and to judge for themselves with the impartiality of philosophers.

Paris wrote a few very indifferent books of annotations on the Epistles to the Romans, to the Galatians, and the Hebrews; but few have ever read them, nor would they have rescued the author from oblivion, without the aid of his lying wonders.

PARKHURST (the Rev. John), was the second son of John Parkhurst, Esq; of Catesby in Northamptonshire. His mother was Ricarda Dormer, daughter of Judge Dormer. He was born in June 1728, was educated at the school of Rugby in Warwickshire, and was afterwards of Clare-hall, Cambridge; B. A. 1748, M. A. 1752; and many years fellow of his college.

Being a younger brother, he was intended for the church; but not long after his entering into holy orders his elder brother died. This event made him the heir of a very considerable estate; though, as his father was still living, it was some time before he came into the full possession of it; and when he did come into the possession of it, the acquisition of fortune produced no change on his manners or his pursuits. He continued to cultivate the studies becoming a clergyman; and from his family connections, as well as from his learning and piety, he certainly had a good right to look forward to preferment in his profession; but betaking himself to retirement, and to a life of close and intense study, he sought for no preferment; and, according to the author of the biographical sketch of him published in the Gentleman's Magazine, he lived not in an age when merit was urged forward. Yet, in the capacity of a curate, but without any salary, he long did the duty, with exemplary diligence and zeal, in his own chapel at Catesby, which, after the demolition of the church of the nunnery there, served as a parish-church, of which also he was the patron.

When, several years after, it fell to his lot to exercise the right of presentation, he was so unfashionable as to consider church-patronage as a trust rather than a property; and, accordingly, resisting the influence of interest, favour, and affection, presented to the vicarage of Epsom, in Surrey, the Rev. Jonathan Boucher, who still holds it. This gentleman was then known to him only by character; but having distinguished himself in America, during the revolution, for his loyalty, and by teaching the unsophisticated doctrines of the church of England to a set of rebellious schismatics at the peril of his life, Mr Parkhurst thought, and justly thought, that he could not present to the vacant living a man who had given better proofs of his having a due sense of the duties of his office.

In the year 1754, Mr Parkhurst married Susanna Myster, daughter, and, we believe, heiress of John Myster, Esq; of Epsom. It was thus that he became patron of the living which he bestowed on Mr Boucher. This lady died in 1759, leaving him a daughter and two sons; both the sons are now dead. In the year 1761, he married again Millicent Northey, daughter of Thomas Northey, Esq; by whom he had one daughter, now married to the Rev. Joseph Thomas.

In the year 1753, he began his career of authorship, by publishing, in 8vo, "A friendly Address to the Rev. Mr John Wesley, in relation to a principal Doctrine maintained by him and his Assistants." This work we have not seen; but though we have no doubt of its value, we may safely say that it was of very little importance, when compared with his next publication, which was "An Hebrew and English Lexicon, without Points; to which is added, a methodical Hebrew Grammar, without Points, adapted to the use of Learners, 1762," 4to. To attempt a vindication of all the etymological and philosophical disquisitions which are scattered through this dictionary, would be very fruitless; but it is not perhaps too much to say, that we have nothing of the kind equal to it in the English language. He continued, however, to correct and improve it; and in 1778 another edition of it came out much enlarged, and a third in 1792.

His philological studies were not confined to the Hebrew language; for he published a Greek and English Lexicon to the New Testament; to which is prefixed, a plain and easy Greek Grammar, 1769, 4to; a second edition, 1794: and at his death there was in the press a new edition of both these lexicons, in a large 8vo, with his last corrections; for he continued to revise, correct, add to, and improve, these works, till within a few weeks of his death. As, from their nature, there cannot be supposed to be any thing in dictionaries that is particularly attractive and alluring, this continued increasing demand for these two seems to be a sufficient proof of their merit.

He published, "The Divinity and Pre-existence of our Lord and Saviour Jesus Christ, demonstrated from Scripture; in Answer to the first Section of Dr Priestley's Introduction to the History of early Opinions concerning Jesus Christ; together with Strictures on some other Parts of the Work, and a Postscript relating to a late Publication of Mr Gilbert Wakefield, 1787," 8vo. This work was very generally regarded as completely performing all that its title page promised; and accordingly the whole edition was soon sold off. The brief, evasive, and very unsatisfactory notice taken of this able pamphlet by Dr Priestley, in "A

Parkhurst. Letter to Dr Horne," &c. shewed only that he was unable to answer it.

Mr Parkhurst was a man of very extraordinary independency of mind and firmness of principle. In early life, along with many other men of distinguished learning, it was also objected to him, that he was an Hutchinsonian; and on this account alone, in common with them, it has been said that he was neglected and shunned.

There is not, in the history of the times, says the biographer already quoted, a circumstance more difficult to be accounted for than the unmerited, but increasing, discountenance shewn to those persons to whom Hutchinsonianism was then objected. Methodists, Papists, and sectaries of any and of every name, all stood a better chance of being noticed and esteemed than Hutchinsonians. Had it even been proved that the few peculiar tenets by which they were distinguished from other Christians were erroneous, the opposition they experienced might have been deemed *hard measure*, because even their opponents allowed their principles to be inoffensive, and themselves to be learned.

Is this a fair state of the case? We think not. The early Hutchinsonians had imbibed all the peculiar notions of their master, and maintained them with a degree of acrimony which would have disgraced any cause. Being in general very little acquainted with the higher mathematics, as Mr Hutchinson himself seems likewise to have been, they censured dogmatically works which, without that knowledge, they could not fully understand; whilst they maintained, with equal dogmatism, as matters of fact, hypotheses, which a moderate share of mathematical science would have shewn them to be impossible. Had they stopt here, no harm would have been done; they might have enjoyed their favourite notions in peace: but unfortunately they accused of Atheism, Deism, or Socinianism, all who thought not exactly as *they* thought, both in natural philosophy and in theology. Because Newton and Clarke had demonstrated that the motions of the planets cannot be the effect of the impulsion of any material fluid, Hutchinson, with some of his followers, affirmed, that these two illustrious men had entered into a serious design to overturn the Christian religion, and establish in England the worship of the Heathen Jupiter, or the Stoical *anima mundi*. Because the Bishops Pearson, Bull, and others, who had uniformly been considered as the ablest defenders of the Catholic faith, thought not exactly as Hutchinson thought of the filiation of the Son of God, they were condemned by the pupils of his school as *Arians*, or at least *Semi-arians*; and the writer of this sketch has heard a living Hutchinsonian pronounce the same censure, and for the same reason, on the present illustrious Bishop of Rochester, and the no less illustrious Whitaker.

That men, who thus condemned all that before them had been deemed great and good in physical science and Christian theology, should meet with some discountenance while they continued of such a spirit, needs not surely excite much wonder; but that the discountenance is increasing, we believe not to be true. The Hutchinsonians, as soon as they became less violent against those who differed from them, had their share of preferment, in proportion to their number, with others; and we doubt not they will continue to have it, while they allow that a man may be no heretic, though he believe not Mr Hutchinson to have been infallible. The late excellent Bishop Horne was an avowed Hutchinsonian, though not an outrageous one like Julius Bate; and we have been told, and have reason to believe, that the Bishop of St Asaph is likewise a moderate favourer of the same system. There may be others on the episcopal bench; but perhaps two out of twenty-six is the full proportion of Hutchinsonian divines of eminence in England. It is true that Mr Parkhurst was a man of great learning and great worth; but before we attribute his want of preferment in the church to his Hutchinsonianism, it is incumbent upon us to say why Mr Whitaker, who is no Hutchinsonian, is still nothing more than the rector of Ruan-Lanyhorne.

Mr Parkhurst, however, was not, if his biographer deserves credit, a thorough-paced Hutchinsonian; for though he continued to read Hutchinson's writings as long as he read at all, he was ever ready to allow, that he was oftentimes a confused and bad writer, and sometimes unbecomingly violent. To have been deterred from reading the works of an author, who, with all his faults, certainly throws out many useful hints, for fear of being thought a Hutchinsonian, would have betrayed a pusillanimity of which Mr Parkhurst was incapable. What he believed he was not afraid to profess; and never professed to believe any thing which he did not very sincerely believe. An earnest lover of truth, he sought it where only it is to be found—in the Scriptures (A). The study of these was at once the business and the pleasure of his life; from his earliest to his latest years, he was an hard student: and had the daily occupations of every 24 hours of his life been portioned out, as it is said those of king Alfred were, into three equal parts, there is reason to believe that a deficiency would rarely have been found in the eight hours allotted to study. What the fruits have been of a life so conducted, few theologians, it is presumed, need to be informed, it being hardly within the scope of a supposition, that any man will now sit down to the study of the Scriptures without availing himself of the assistance to be obtained from his learned labours. These labours ceased at Epsom in Surrey, where this great and good man died, on March the 21st, 1797. Besides the works which we have mentioned, there is in the Gentleman's Magazine, for August 1797, a curious letter of his on the Confusion of Tongues at Babel.

Mr Parkhurst's character may be collected with tolerable accuracy even from this imperfect sketch of his life. His notions of church patronage do him honour; and as a farther instance of the high sense he entertained

(A) This is vague language, which is the source of much useless controversy, and therefore ought to be avoided. by *truth*, in this passage, be meant *religious* truth, we admit the assertion in the only sense in which we think can have been made. If the author means *all* truth, he writes nonsense; for the Scriptures treat not of *geo-'ry* or *algebra*, where truth is certainly to be found; and *we think* that they have a higher object than even *hanics* and *astronomy*.

Parkhurst, Parkinson.

ed of strict justice, and the steady resolution with which he practised it on all occasions, an incident which occurred between him and one of his tenants, within these ten years, may here be mentioned. This man falling behind hand in the payment of his rent, which was L. 500 *per annum*, it was represented to his landlord that it was owing to his being over rented. This being believed to be the case, a new valuation was made; and it was then agreed that, for the future, the rent should not be more than L. 450. Justly inferring, moreover, that if the farm was *then* too dear, it must necessarily have been *always* too dear, unasked, and of his own accord, he immediately struck off L. 50 from the commencement of the lease; and instantly refunded all that he had received more than L. 450 *per annum*.

Mr Parkhurst was in his person rather below the middle size, but remarkably upright, and firm in his gait. He was all his life of a sickly habit: and his leading so remarkably studious and sedentary a life (it having, for many years, been his constant practice to rise at five, and, in winter, to light his own fire) to the very verge of David's limits of the life of man, is a consolatory proof to men of similar habits, how much, under many disadvantages, may still be effected by strict temperance and a careful regimen. He also gave less of his time to the ordinary interruptions of life than is common. In an hospitable, friendly, and pleasant neighbourhood, he visited little; alleging, that such a course of life neither suited his temper, his health, nor his studies. Yet he was of sociable manners; and his conversation always instructive, often delightful: for his stores of knowledge were so large, that he too has often been called a walking library. He belonged to no clubs; he frequented no public places; and there are few men who, towards the close of life, may not, on a retrospect, reflect with shame and sorrow, how much of their precious time has thus been thrown away, or, perhaps, worse than thrown away.

Like many other men of infirm and sickly frames, Mr Parkhurst was also irritable, and quick, warm, and earnest, in his resentments, though never unforgiving. But whether it be or be not a matter of reproach to possess a mind so constituted, it certainly is much to any man's credit to counteract and subdue it by an attention to the injunctions of religion. This Mr Parkhurst effectually did: and few men have passed through a long life more at peace with his neighbours, more respected by men of learning, more beloved by his friends, or more honoured by his family.

PARKINSON (John). Of this ingenious English botanist, one of the first and most industrious cultivators of that science among us, the memorials that remain are very scanty. He was born in 1567, was bred an apothecary, and resided in London. He rose to such reputation in his profession as to be appointed apothecary to King James I.; and, on the publication of his Theatre of Plants, he obtained from the unfortunate successor of that prince the title of *Botanicus Regis primarius*. The time of his death cannot be exactly ascertained; but, as his Herbal was published in 1640, and it appears that he was living at that time, he must have attained his 73d year. *Biog. Dict.*

Parkinson's first publication was, his 1. *Paradisi in Sole Paradisus terrestris*, or, A Garden of all Sorts of Pleasant Flower which our English Ayre will permit to be nursed up with a Kitchen garden of all manner of Herbes, Roots, and Fruits, for Meat or Sause, &c. &c. Collected by John Parkinson apothecary, of London, 1629, folio, 612 pages. In this work the plants are arranged without any exact order: nearly 1000 plants are separately described, of which 780 are figured on 129 tables, which appear to have been cut expressly for this work. Parkinson was, it is conceived, the first English author who separately described and figured the subjects of the flower garden; and this book is therefore a valuable curiosity, as exhibiting a complete view of the extent of the English garden at the beginning of the last century. It may, perhaps, be necessary to inform the reader, that Paradisus in Sole, is meant to express the author's name, *Park in sun*. 2. In 1640 he published his *Theatrum Botanicum*; or Theatre of Plants, or an Herbal of a large extent: containing therein, a more ample and exact History and declaration of the Physical Herbs and Plants than are in other Authors, &c. &c. London, folio, 1745 pages. This work had been the labour of the author's life; and he tells us that, owing to "the disastrous times," and other impediments, the printing of it was long retarded. Dr Pulteney is of opinion, that, allowing for the defects common to the age, Parkinson will appear "more of an original author than Gerard or Johnson, independent of the advantages he might derive from being posterior to them. His theatre was carried on through a long series of years, and he profited by the works of some late authors, which Johnson, though they were equally in his power, had neglected to use. Parkinson's descriptions, in many instances, appear to be new. He is more particular in pointing out the places of growth. Johnson had described about 2850 plants. Parkinson has near 3800. These accumulations rendered the *Theatrum Botanicum* the most copious book on the subject in the English language; and it may be presumed, that it gained equally the approbation of medical people, and of all those who were curious and inquisitive in this kind of knowledge."

Parkinson, Parsons.

PARSONS (James), an excellent physician and polite scholar, was born at Barnstaple, in Devonshire, in March 1705. His father, who was the youngest of nine sons of Colonel Parsons, and nearly related to the baronet of that name, being appointed barrack-master at Bolton in Ireland, removed with his family into that kingdom soon after the birth of his then only son, James, who received at Dublin the early part of his education, and, by the assistance of proper masters, laid a considerable foundation of classical and other useful learning, which enabled him to become tutor to Lord Kingston. Turning his attention to the study of medicine, he went afterwards to Paris, where (to use his own words) "he followed the most eminent professors in the several schools, as Astruc, Dubois, Lemery, and others; attended the anatomical lectures of the most famous [Hunaud and De Cat]; and chemicals at the King's Garden at St Come. He followed the physicians in both hospitals of the Hotel Dieu and La Charité, and the chemical lectures and demonstrations of Lemery and Bouldoc; and in botany Jussieu. Having finished these studies, his professors gave him honourable attestations of his having followed them with dili-

gence

Parsons.

gence and industry, which intitled him to take the degrees of doctor and professor of the art of medicine, in any university in the dominions of France. Intending to return to England, he judged it unnecessary to take degrees in Paris, unless he had resolved to reside there; and as it was more expensive, he therefore went to the university of Rheims, in Champaign, where, by virtue of his attestations, he was immediately admitted to three examinations, as if he had finished his studies in that academy; and there was honoured with his degrees June 11. 1736. In the July following he came to London, and was soon employed by Dr James Douglas to assist him in his anatomical works, where in some time he began to practise. He was elected a member of the Royal Society in 1740; and, after due examination, was admitted a licentiate of the college of physicians April 1. 1751; paying college fees and bond stamps of different denominations to the amount of L. 41 : 2 : 8, subject also to quarterage of L. 2 *per annum*. In 1755 he paid a farther sum of L. 7, which, with the quarterage money already paid, made up the sum of L. 16, in lieu of all future payments." On his arrival in London, by the recommendation of his Paris friends, he was introduced to the acquaintance of Dr Mead, Sir Hans Sloane, and Dr James Douglas. The great anatomist made use of his assistance, not only in his anatomical preparations, but also in his representations of morbid and other appearances; a list of several of which was in the hands of his friend Dr Maty, who had prepared an *eloge* on Dr Parsons, which was never used, but which, by the favour of Mrs Parsons, Mr Nichols has preserved at large. Though Dr Parsons cultivated the several branches of the profession of physic, he was principally employed in the obstetrical line. In 1738, by the interest of his friend Dr Douglas, he was appointed physician to the public infirmary in St Giles's. In 1739 he married Miss Elizabeth Reynolds, by whom he had two sons and a daughter, who all died young. Dr Parsons resided for many years in Red Lion Square, where he frequently enjoyed the company and conversation of Dr Stukely, Bishop Lyttleton, Mr Henry Baker, Dr Knight, and many other of the most distinguished members of the Royal and Antiquarian Societies, and that of Arts, Manufactures, and Commerce; giving weekly an elegant dinner to a large but select party. He enjoyed also the literary correspondence of D'Argenville, Buffon, Le Cat, Beccaria, Amb. Bertrand, Valltravers, Ascanius, Turberville Needham, Dr Garden, and others of the most distinguished rank in science. As a practitioner, he was judicious, careful, honest, and remarkably humane to the poor; as a friend, obliging and communicative; chearful and decent in conversation, severe and strict in his morals, and attentive to fill with propriety all the various duties of life. In 1769, finding his health impaired, he proposed to retire from business and from London; and with that view disposed of a considerable number of his books and fossils, and went to Bristol. But he returned soon after to his old house, and died in it after a week's illness, on the 4th of April, 1770. By his last will, dated in October 1766, he gave his whole property to Mrs Parsons; and in case of her death before him, to Miss Mary Reynolds her only sister, "in recompence for her affectionate attention to him and to his wife, for a long course of years, in sickness and in health." It was his particular request, that he should not be buried till some change should appear in his corpse; a request which occasioned him to be kept unburied 17 days, and even then scarce the slightest alteration was perceivable. He was buried at Hendon, in a vault which he had caused to be built on the ground purchased on the death of his son James, where his tomb had a very commendatory inscription.

Parsons.

It would carry us beyond our usual limits to enter into an enumeration of the many curious articles at various times communicated to the public by Dr Parsons, which may be seen in the Anecdotes of Bowyer. We shall therefore close this article with an extract from Dr Maty's eulogium: "The surprising variety of branches which Dr Parsons embraced, and the several living as well as dead languages he had a knowledge of, qualified him abundantly for the place of assistant secretary for foreign correspondences, which the council of the Royal Society bestowed upon him about the year 1750. He acquitted himself to the utmost of his power of the functions of this place, till a few years before his death, when he resigned in favour of his friend, who now gratefully pays this last tribute to his memory. Dr Parsons joined to his academical honours those which the Royal College of Physicians of London bestowed upon him, by admitting him, after due examination, licentiate, on the first day of April 1751. The diffusive spirit of our friend was only equalled by his desire of information. To both these principles he owed the intimacies which he formed with some of the greatest men of his time. The names of Folkes, Hales, Mead, Stukely, Needham, Baker, Collinson, and Garden, may be mentioned on this occasion, and many more might be added. Weekly meetings were formed, where the earliest intelligence was received and communicated of any discovery both here and abroad; and new trials were made, to bring to the test of experience the reality or usefulness of these discoveries. Here it was that the microscopical animals found in several infusions were first produced; the propagation of several insects by section ascertained; the constancy of Nature amidst these wonderful changes established. His Remains of Japhet, being Historical Enquiries into the Affinity and Origin of the European Languages, are a most laborious performance, tending to prove the antiquity of the first inhabitants of these islands as being originally descended from Gomer and Magog, above 1000 years before Christ, their primitive and still subsisting language, and its affinity with some others. It cannot be denied but that there is much ingenuity, as well as true learning, in this work, which helps conviction, and often supplies the want of it. But we cannot help thinking that our friend's warm feelings now and then mislead his judgment, and that some at least of his conjectures, resting upon partial traditions, and poetical scraps of Irish filids and Welsh bards, are less satisfactory than his tables of affinity between the several northern languages, as deduced from one common stock. Literature, however, is much obliged to him for having in this, as well as in many of his other works, opened a new field of observations and discoveries. In enumerating our learned friend's dissertations, we find ourselves at a loss whether we should follow the order of subjects or of time; neither is it easy to account

Parſons. account for their ſurpriſing variety and quick ſucceſſion. The truth is, that his eagerneſs after knowledge was ſuch, as to embrace almoſt with equal facility all its branches, and with equal zeal to aſcertain the merit of inventions, and aſcribe to their reſpective, and ſometimes unknown, authors, the glory of the diſcovery. Many operations, which the ancients have tranſmitted to us, have been thought fabulous, merely from our ignorance of the art by which they were performed. Thus the burning of the ſhips of the Romans at a conſiderable diſtance, during the ſiege of Syracuſe, by Archimedes, would perhaps ſtill continue to be exploded, had not the celebrated M. Buffon in France ſhewn the poſſibility of it, by preſenting and deſcribing a model of a ſpeculum, or rather aſſemblage of mirrors, by which he could ſet fire at the diſtance of ſeveral hundred feet. In the contriving, indeed, though not in the executing of ſuch an apparatus, he had in ſome meaſure been foreſtalled by a writer now very little known or read. This Dr Parſons proved in a very ſatisfactory manner; and he had the pleaſure to find the French philoſopher did not refuſe to the Jeſuit his ſhare in the invention, and was not at all offended by the liberty he had taken. Another French diſcovery, I mean a new kind of painting fathered upon the ancients, was reduced to its real value, in a paper which ſhewed our author was poſſeſſed of a good taſte for the fine arts: and I am informed that his ſkill in muſic was by no means inferior, and that his favourite amuſement was the flute. Richly, it appears from theſe performances, did our author merit the honour of being a member of the Antiquarian Society, which long ago had aſſociated him to its labours. To another ſociety, founded upon the great principles of humanity, patriotiſm, and natural emulation, he undoubtedly was greatly uſeful (A). He aſſiſted at moſt of their general meetings and committees, and was for many years chairman to that of agriculture; always equally ready to point out and to promote uſeful improvements, and to oppoſe the intereſted views of fraud and ignorance, ſo inſeparable from very extenſive aſſociations. No ſooner was *this* ſociety (B) formed, than Dr Parſons became a member of it. Intimately convinced of the nobleneſs of its views, though from his ſtation in life little concerned in its ſucceſs, he grudged neither attendance nor expence. Neither ambitious of taking the lead, nor fond of oppoſition, he joined in any meaſure he thought right; and ſubmitted cheerfully to the ſentiments of the majority, though againſt his own private opinion. The juſt ideas he had of the dignity of our profeſſion, as well as of the common links which ought to unite all its members, notwithſtanding the differences of country, religion, or places of education, made him bear impatiently the ſhackles laid upon a great number of reſpectable practitioners: he wiſhed, fondly wiſhed, to ſee theſe broken; not with a view of empty honour and dangerous power, but as the only means of ſerving mankind more effectually, checking the progreſs of deſigning men and illiterate practitioners, and diffuſing through the whole body a ſpirit of emulation. Though, by frequent diſappointments he ſaw, as well as we, the little chance of a ſpeedy redreſs, he nobly perſiſted in the attempt; and had he lived to the final event, would undoubtedly, like Cato, [illegible] have preferred the conquered cauſe to that ſupported by the gods. After having [illegible] from London, for the ſake of his health, and having diſpoſed of moſt of his books with that view, he found it inconſiſtent with his happineſs to forſake all the advantages which a long reſidence in the capital, and the many connections he had formed, had rendered habitual to him. He therefore returned to his old houſe, and died in it, after a ſhort illneſs, April [illegible] 1770. The ſtyle of our friend's compoſition was ſufficiently clear in deſcription, tho' in argument not ſo cloſe as could have been wiſhed. Full of his ideas, he did not always ſo diſpoſe and connect them together, as to produce in the minds of his readers that conviction which was in his own. He too much deſpiſed thoſe additional graces which command attention when joined to learning, obſervation, and ſound reaſoning. Let us hope that his example and ſpirit will animate all his colleagues; and that thoſe practitioners who are in the ſame circumſtances will be induced to join their brethren, ſure to find among them thoſe great bleſſings of life, freedom, equality, information, and friendſhip. As long as theſe great principles ſhall ſubſiſt in this ſociety, and I truſt they will outlaſt the longeſt liver, there is no doubt but the members will meet with the reward honeſt men are ambitious of, the approbation of their conſcience, the eſteem of the virtuous, the remembrance of poſterity."

PARODICAL DEGREES, in an equation, a term that has been ſometimes uſed to denote the ſeveral regular terms in a quadratic, cubic, biquadratic, &c. equation, when the indices of the powers aſcend or deſcend orderly in an arithmetical progreſſion. Thus $x^3 + mx^2 + nx = p$ is a cubic equation where no term is wanting, but having all its parodic degrees; the indices of the terms regularly deſcending thus, 3, 2, 1, 0.

PARTY ARCHES, in architecture, are arches built between ſeparate tenures, where the property is intermixed, and apartments over each other do not belong to the ſame eſtate.

Party Walls, are partitions of brick made between buildings in ſeparate occupations, for preventing the ſpread of fire. Theſe are made thicker than the external walls; and their thickneſs in London is regulated by act of Parliament of the 14th of George III.

PASSIGRAPHY, the art of writing on any ſubject ſo as to be underſtood by all nations (See *Univerſal* CHARACTERS in this *Supplement*). In France, where every thing is admired that is new, and every vagary of the imagination of a pretended philoſopher thought practicable, a propoſal has lately been made to introduce one univerſal language into the world, conſtructed by a few metaphyſicians on the laws of human thought. And to this language, in its written form, is to be given the name of *paſſigraphy*. Such readers as think this idle dream

(A) The Society for the Encouragement of Arts, Manufactures, and Commerce. He likewiſe was aſſociated to the Economical Society at Berne, Dec. 26. 1763.

(c) A Medical Society inſtituted by Dr Fothergill, and other reſpectable phyſicians, licentiates, in vindication of their privileges; where, it ſhould ſeem, this eulogy was intended to be pronounced.

dream worthy their attention (which is far from being the case with us), will find some ingenious thoughts on the history of a philosophical language, in the 2d volume of *Nicholson's Journal of Natural Philosophy*, &c.

PATH OF THE VERTEX, a term frequently used by Mr Hamilton, in his Doctrine of the Sphere, denoting a circle, described by any point of the earth's surface as the earth turns round its axis. This point is considered as vertical to the earth's centre; and is the same with what is called the vertex or zenith in the Ptolomaic projection.

PEARL FISH, is commonly considered as an *ascidia* (see MYTILUS, *Encycl.*); but this is denied by a late author, who seems to have paid great attention to the pearl fishery at Ceylon. It has never, he says, been accurately described. It does not resemble the *ascidia* of Linnæus; and as he thinks it may form a new genus, he gives the following account of it:

"The fish is fastened to the upper and lower shells by two white flat pieces of muscular substance, which have been called ears, and extend about two inches from the thick part of the body, growing gradually thinner. The extremity of each ear lies loose, and is surrounded by a double brown fringed line. These lie almost the third part of an inch from the outer part of the shell, and are continually moved by the animal. Next to these, above and below, are situated two other double fringed moveable substances, like the bronchiæ of a fish. These ears and fringes are joined to a cylindrical piece of flesh of the size of a man's thumb, which is harder and of a more muscular nature than the rest of the body. It lies about the centre of the shells, and is firmly attached to the middle of each. This, in fact, is that part of the pearl fish which serves to open and shut the shells. Where this column is fastened, we find on the flesh deep impressions, and on the shell various nodes of round or oblong forms, like imperfect pearls. Between this part and the hinge (*cardo*) lies the principal body of the animal, separated from the rest, and shaped like a bag. The mouth is near the hinge of the shell, enveloped in a veil, and has a double flap or lip on each side; from thence we observe the throat (*œsophagus*) descending like a thread to the stomach. Close to the mouth there is a curved brownish tongue, half an inch in length, with an obtuse point; on the concave side of this descends a furrow, which the animal opens and shuts, and probably uses to convey food to its mouth. Near its middle are two bluish spots, which seem to be the eyes. In a pretty deep hole, near the base of the tongue, lies the beard (*byssus*), fastened by two fleshy roots, and consisting of almost 100 fibres, each an inch long, of a dark green colour, with a metallic lustre; they are undivided, parallel, and flattened. In general, the *byssus* is more than three quarters of an inch without the cleft (*rima*); but if the animal is disturbed, it contracts it considerably. The top of each of these threads terminates in a circular gland or head, like the *stigma* of many plants. With this *byssus* they fasten themselves to rocks, corals, and other solid bodies; by it the young pearl-fish cling to the old ones, and with it the animal procures its food, by extending and contracting it at pleasure. Small shell fish, on which they partly live, are often found clinging to the former. The stomach lies close to the root of the beard, and has, on its lower side, a protracted obtuse point. Above the stomach are two small red bodies, like lungs; and from the stomach goes a long channel or gut, which takes a circuit round the muscular column above-mentioned, and ends in the anus, which lies opposite to the mouth, and is covered with a small thin leaf, like a flap. Though the natives pretend to distinguish the sexes by the appearance of the shell, calling the flat ones males, and those which are thick, concave, and vaulted, females, our author, on a close inspection, could not perceive any visible sexual difference."

The pearls are only in the softer part of the animal, and never in the firm muscular column above-mentioned. They are found, in general, near the earth, and on both sides of the mouth. From the appearance of the shell a judgment may be formed, with greater or less probability, whether it contains pearls or not. Those which have a thick calcareous crust upon them, to which *serpulæ* (sea tubes) *Tubuli marini irregulariter intorti*, *Crista gali Chamar lazurus*, *Lepas tintinabulum*, *Madreporee*, *Millipore*, *Cellipore*, *Gorgoniæ*, *Spongiæ*, and other Zoophytes, are fastened, have arrived at their full growth, and commonly contain the best pearls; but those that appear smooth, contain either none, or small ones only.

In the article (*Encycl.*) intitled, *Manner of Fishing for* PEARLS *in the East Indies*, we have most unaccountably said, that "the best divers will keep under water near *half an hour*, and the rest not less than a quarter!" This is a very great mistake; for M. *Le Beck* assures us, that the time during which a diver is able to remain under water seldom exceeds two minutes; and that, even after that short period, he discharges, on emerging from the sea, a quantity of water, and sometimes a little blood, from his mouth and nose. We have mentioned the danger which the divers run of becoming a prey to monstrous fishes. These fishes are sharks; of which such a dread is justly entertained, that the most expert divers will not, on any account, descend, till the conjurer has performed his ceremonies of inchantment. These consist in a number of prayers, learned by heart, that nobody, probably not even the conjurer himself, understands, which he, standing on the shore, continues muttering and grumbling from sun rise until the boats return. During this period, he is obliged to abstain from food and sleep, otherwise his prayers would have no avail: he is, however, allowed to drink; which privilege he indulges in a high degree, and is frequently so giddy, as to be rendered very unfit for devotion. Some of the conjurers accompany the divers in their boats; which pleases them very much, as they have their protectors near at hand.

PEDOMETER (see *Encycl.*), is the name given by Mr Lewin Thugwell to an instrument, which is rather an improved PERAMBULATOR than the instrument which we have noticed by the name of Pedometer. The chief improvement made by him on the PERAMBULATOR (see that article, *Encycl.*) is in the size of the wheel, of which the circumference measures 16½ feet, or one pole, adapted to Gunter's concise method of arithmetic, and divided into 25 equal parts, corresponding to the links of his chain for land measuring. There is likewise a contrivance in Mr Thugwell's pedometer, for compelling the attention of the traveller to the instrument at the end of every mile. It is very ingenious, and abundantly simple; but we hardly think it of sufficient

Pegue. cient importance to fill the ſpace which a complete deſcription of it would occupy in this Work. It is fully deſcribed in the *Letters and Papers of the Bath and Weſt of England Society, for the Encouragement of Agriculture;* and likewiſe in the 6th volume of the *Repertory of Arts and Manufactures.*

PEGUE, the ancient capital of the kingdom of the ſame name (ſee PEGU, *Encycl.*), appears to have been a quadrangle, each ſide meaſuring about a mile and a half. It was ſurrounded by a ditch and wall; which, before the latter tumbled down, and the former was filled up, muſt have furniſhed no contemptible defence. The breadth of the ditch appears to be about 60 yards; its depth, where not choked up, about ten or twelve feet; and there is ſtill in it water enough to impede an eaſtern ſiege. The wall has been at leaſt 25 feet high, and its breadth at the baſe not leſs than 40. It is compoſed of brick, badly cemented together with clay mortar, and has ~~had on it ſmall~~ equidiſtant baſtions, about 300 yards aſunder.

Nothing can exhibit a more ſtriking picture of deſolation than the inſide of this wall. We have elſewhere given an account of the almoſt inceſſant wars between the kings of Pegue and Birma or Barma. In the year 1757, the Birman ſovereign carried the city of Pegue by aſſault, razed every dwelling to the ground, and diſperſed, or led into captivity, all the inhabitants. The pagodas, which are very numerous, were the only buildings that eſcaped the fury of the conqueror; and of theſe the great pagoda of SHOEMADOO has alone been attended to, and repaired.

This extraordinary edifice is built on a double terrace, one raiſed upon another. The lower and greater terrace is about ten feet above the natural level of the ground. It is quadrangular. The upper and leſſer terrace is of a like ſhape, raiſed about 20 feet above the lower terrace, or 30 above the level of the country. Theſe terraces are aſcended by flights of ſtone ſteps, broken and neglected. On each ſide are dwellings of the *Rahaans* or prieſts, raiſed on timbers four or five feet from the ground. Their houſes conſiſt only of a ſingle hall. The wooden pillars that ſupport them are turned with neatneſs. The roof is of tile, and the ſides of ſheathing-boards. There are a number of bare benches in every houſe, on which the *Rahaans* ſleep. They appear to have no furniture.

Shoemadoo is a pyramid, compoſed of brick and plaſter, with fine ſhell mortar, without excavation or aperture of any ſort; octagonal at the baſe, and ſpiral at the top. Six feet from the ground there is a wide ledge, which ſurrounds the baſe of the building; on the plane of which are 57 ſmall ſpires, of equal ſize, and equidiſtant. One of them meaſured 27 feet in height, and 40 in circumference at the bottom. On a higher ledge there is another row, conſiſting of 53 ſpires, of ſimilar ſhape and meaſurement. A great variety of mouldings encircles the building; and ornaments, ſomewhat reſembling the *fleur de lys*, ſurround what may be called the baſe of the ſpire. Circular mouldings likewiſe gird this part to a conſiderable height; above which there are ornaments in ſtucco, not unlike the leaves of a Corinthian capital; and the whole is crowned by a *tee*, or umbrella of open iron-work, from which riſes an iron rod with a gilded penant.

The extreme height of the building, from the level of the country, is 361 feet; and above the interior terrace, 331 feet. On the ſouth eaſt angle of the upper terrace there are two handſome ſaloons, or *leouns*, lately erected. The roof is compoſed of different ſtages, ſupported by pillars. Captain Symes, from whoſe memoir in the Aſiatic Reſearches this account is taken, judged the length of each ſaloon to be about 6. feet, and the breadth 30. The ceiling of one of them was already embelliſhed with gold leaf, and the pillars lacquered; the other, when he ſaw it, was not completed. They are made entirely of wood. The carving on the outſide is very curious. He ſaw ſeveral unfiniſhed figures, intended to be fixed on different parts of the building; ſome of them not ill ſhapen, and many exceedingly groteſque. Splendid images of Gaudma (the *Birman* object of adoration) were preparing, which he underſtood were deſigned to occupy the inſide of theſe *leouns*.

At each angle of the interior terrace is a pyramidical pagoda, 67 feet in height, reſembling, in miniature, the great pagoda. In front of the one in the ſouth weſt corner are four gigantic repreſentations in maſonry of Palloo, or the *man deſtroyer*, half beaſt, half human, ſeated on their hams, each with a large club on the right ſhoulder.

Nearly in the centre of the eaſt face of the area are two human figures in ſtucco beneath a gilded umbrella. One ſtanding, repreſents a man with a book before him, and a pen in his hand. He is called *Thagiamee*, the recorder of mortal merits and mortal miſdeeds. The other, a female figure kneeling, is *Maha Sumdere*, the protectreſs of the univerſe, as long as the univerſe is doomed to laſt: but when the time of general diſſolution arrives, by her hand the world is to be overwhelmed, and deſtroyed everlaſtingly.

On the north ſide of the great pagoda are three large bells, of good workmanſhip, ſuſpended near the ground between pillars. Several deers horns are ſtrewed around. Thoſe who come to pay their devotions firſt take up one of the horns, and ſtrike the bell three times, giving an alternate ſtroke to the ground. This act is to announce to the ſpirit of Gaudma the approach of a ſuppliant. There are ſeveral low benches near the bottom of the pagoda, on which the perſon who comes to pray places his offering; which generally conſiſts of boiled rice, a plate of ſweetmeats, or cocoa-nut fried in oil. When it is given, the devotee cares not what becomes of it. The crows and dogs commonly eat it up in the preſence of the donor, who never attempts to prevent or moleſt the animals.

There are many ſmall pagodas on the areas of both terraces, which are neglected, and ſuffered to fall into decay. Numberleſs images of Gaudma lie indiſcriminately ſcattered. A pious Birman who purchaſes an idol, firſt procures the ceremony of conſecration to be performed by the *Rahaans*, then takes his purchaſe to whatever ſacred building is moſt convenient, and there places it either in the ſhelter of a *leoun*, or on the open ground before the temple: nor does he ever after ſeem to have any anxiety about its preſervation, but leaves the divinity to ſhift for itſelf.

From the upper ledge that ſurrounds the baſe of Shoemadoo, the proſpect of the country is extenſive and pictureſque; but it is a proſpect of Nature in her rudeſt ſtate. There are few inhabitants, and ſcarcely any

Pegue. any cultivation. The hills of *Martaban* riſe to the eaſtward; and the *Sitang* river, winding along the plains, gives here and there an interrupted view of its waters. To the north-north weſt, above 40 miles, are the *Galladzet* hills, whence the Pegue river takes its riſe; hills remarkable only for the noiſome effects of their atmoſphere. In every other direction the eye looks over a boundleſs plain, chequered by a wild intermixture of wood and water.

The preſent king of the Birmans has entirely altered the ſyſtem of his predeceſſors. He has turned his attention to the population and improvement, rather than the extenſion, of his dominions; and ſeems more deſirous to conciliate his new ſubjects by mildneſs, than to rule them through terror. He has abrogated ſeveral ſevere penal laws impoſed upon the *Taliens* or Peguers: juſtice is now diſtributed impartially; and the only diſtinction at preſent between a Birman and Talien conſiſts in the excluſion of the latter from all public offices of truſt and power.

No act of the Birman government is more likely to reconcile the Taliens to the Birman yoke than the reſtoration of their ancient place of abode, and the preſervation and embelliſhment of the pagoda of Shoemadoo. So ſenſible was the king of this, as well as of the advantages that muſt accrue to the ſtate from an increaſe of culture and population, that ſome years ago he iſſued orders to rebuild Pegue, encouraged new ſettlers by liberal grants, and invited the ſcattered families of former inhabitants to return and repeople their deſerted city.

Pegue, in its renovated ſtate, ſeems to be built on the plan of the former city. It is a ſquare, each ſide meaſuring about half a mile. It is fenced round by a ſtockade, from 10 to 12 feet high. There is one main ſtreet running eaſt and weſt, which is interſected at right angles by two ſmaller ſtreets, not yet finiſhed. At each extremity of the principal ſtreet there is a gate in the ſtockade, which is ſhut early in the evening. After that hour, entrance during the night is confined to a wicket. Each of theſe gates is defended by a ſorry piece of ordnance, and a few muſqueteers, who never poſt centinels, and are uſually aſleep. There are alſo two other gates on the north and ſouth ſides of the ſtockade.

The houſes of the inhabitants of Pegue are far from commodious, agreeably to European notions of accommodation; but they are at leaſt as much ſo as the houſes of other Indian towns. There are no brick buildings in Pegue, except ſuch as belong to the king, or are dedicated to Gaudma. The king has prohibited the uſe of brick or ſtone in private buildings, from the apprehenſion, that if people got leave to build brick houſes, they might erect brick fortifications, dangerous to the ſecurity of the ſtate. The houſes, therefore, are all made of mats or ſheathing boards, ſupported on bamboos or poſts. Being compoſed of ſuch combuſtible materials, the inhabitants are under continual dread of fire, againſt which they take every precaution. The roofs are lightly covered; and at each door ſtands a long bamboo, with a hook at the end, to pull down the thatch; alſo another pole, with a grating of ſplit bamboo at the extremity, about three feet ſquare, to ſuppreſs flame by preſſure. Almoſt every houſe has earthen pots of water on the roof. And there is a particular claſs of people, whoſe buſineſs it is to prevent and extinguiſh fires.

PEISHCAR, in Bengal, principal in office.

PEISHCUSH, a fine, tribute, or preſent.

PELL (Dr John), an eminent Engliſh mathematician, deſcended from an ancient family in Lincolnſhire, was born at Southwick in Suſſex, March 1. 1610, where his father was miniſter. He received his grammar education at the free ſchool at Stenning in that county. At the age of 13 he was ſent to Trinity college in Cambridge, being then as good a ſcholar as moſt maſters of arts in that univerſity; but though he was eminently ſkilled in the Greek and Hebrew languages, he never offered himſelf a candidate at the election of ſcholars or fellows of his college. His perſon was handſome; and being of a ſtrong conſtitution, uſing little or no recreations, he proſecuted his ſtudies with the more application and intenſeneſs.

In 1629 he drew up the "Deſcription and Uſe of the Quadrant, written for the Uſe of a Friend," in two books; the original manuſcript of which is ſtill extant among his papers in the Royal Society. And the ſame year he held a correſpondence with Mr Briggs on the ſubject of logarithms.

In 1630, he wrote *Modus ſupputandi Ephemerides Aſtronomicas, &c. ad an.* 1630 *accommodatus;* and, A Key to unlock the meaning of Johannes Trithemius, in his Diſcourſe on Steganography: which Key he imparted to Mr Samuel Hartlib and Mr Jacob Homedæ. The ſame year he took the degree of Maſter of Arts at Cambridge. And the year following he was incorporated in the univerſity of Oxford. June the 7th, he wrote A Letter to Mr Edmond Wingate on Logarithms: and, Oct. 5. 1631, *Commentationes in Coſinographiam Alſtedii.*

In 1632 he married Ithamaria, ſecond daughter of Mr Henry Reginolles of London, by whom he had four ſons and four daughters.—March 6. 1634, he finiſhed his "Aſtronomical Hiſtory of Obſervations of Heavenly Motions and Appearances;" and April the 10th, his *Ecliptica Prognoſtica*, or Foreknower of the Eclipſes, &c. In 1634 he tranſlated "The Everlaſting Tables of Heavenly Motions," grounded upon the Obſervations of all Times, and agreeing with them all, by Philip Lanſberg, of Ghent in Flanders. And June the 12th, the ſame year, he committed to writing "The Manner of Deducing his Aſtronomical Tables out of the Tables and Axioms of Philip Lanſberg."—March the 9th, 1625, he wrote "A Letter of Remarks on Gellibrand's Mathematical Diſcourſe on the Variation of the Magnetic Needle" And the 3d of June following, another on the ſame ſubject.

His eminence in mathematical knowledge was now ſo great, that he was thought worthy of a Profeſſor's chair in that ſcience; and, upon the vacancy of one at Amſterdam in 1639, Sir William Boſwell, the Engliſh Reſident with the States General, uſed his intereſt, that he might ſucceed in that Profeſſorſhip. It was not filled up, however, till 1643, when Pell was choſen to it; and he read with great applauſe public lectures upon Diophantus.—In 1644 he printed at Amſterdam, in two pages 4to, "A Refutation of Longomontanus's Diſcourſe," *De Vera Circuli Menſura.*

Pell.

In 1646, on the invitation of the Prince of Orange, he removed to the new college at Breda, as Professor of Mathematics, with a salary of 1000 guilders a year. His *Idea Matheseos*, which he had addressed to Mr Hartlib, who in 1639 had sent it to Des Cartes and Mersenne, was printed 1650 at London, in 12mo, in English, with the title of *An Idea of Mathematics*, at the end of Mr John Durie's Reformed Library keeper. It is also printed by Mr Hook, in his Philosophical Collections, N° 5. p. 127.; and is esteemed our author's principal work.

In 1652 Pell returned to England; and in 1654 he was sent by the protector Cromwell agent to the Protestant Cantons in Switzerland; where he continued till June 23. 1658, when he set out for England, where he arrived about the time of Cromwell's death. His negociations abroad gave afterwards a general satisfaction, as it appeared he had done no small service to the interest of King Charles II. and of the church of England; so that he was encouraged to enter into holy orders: and in the year 1661 he was instituted to the rectory of Fobbing in Essex, given him by the king. In December that year, he brought into the upper house of convocation the calendar reformed by him, assisted by Sancroft, afterwards archbishop of Canterbury. In 167 he was presented by Sheldon, bishop of London, to the rectory of Laingdon in Essex; and, upon the promotion of that bishop to the see of Canterbury soon after, became one of his domestic chaplains. He was then doctor of divinity, and expected to be made a dean; but his improvement in the philosophical and mathematical sciences was so much the bent of his genius, that he did not much pursue his private advantage. The truth is, he was a helpless man, as to worldly affairs; and his tenants and relations imposed upon him, cozened him of the profits of his parsonage, and kept him so indigent, that he wanted necessaries, even ink and paper, to his dying day. He was for some time confined to the King's-bench prison for debt; but, in March 1682, was invited by Dr Whitler to live in the college of physicians. Here he continued till June following; when he was obliged, by his ill state of health, to remove to the house of a grandchild of his in St Margaret's church-yard, Westminster. But he died at the house of Mr Cothorne, reader of the church of St Giles's in the Fields, December the 12th, 1685, in the 74th year of his age, and was interred at the expence of Dr Busby, master of Westminster school, and Mr Sharp, rector of St Giles's, in the rector's vault under that church.—Dr Pell published some other things not yet mentioned; a list of which is as follows, *viz.*

1. An Exercitation concerning Easter; 1644, in 4to. 2. A Table of 10,000 square numbers, &c.; 1672, folio. 3. An Inaugural Oration at his entering upon the Professorship at Breda. 4. He made great alterations and additions to Rhonius's Algebra, printed at London 1668, 4to, under the title of An Introduction to Algebra, translated out of the High Dutch into English by Thomas Branker, much altered and augmented by D. P. (Dr Pell). Also a Table of Odd Numbers, less than 100,000, shewing those that are incomposite, &c. supputated by the same Thomas Branker. 5. His Controversy with Longomontanus concerning the Quadrature of the Circle; Amsterdam, 1646, 4to.

Pell
Pelletier.

He likewise wrote a Demonstration of the 2d and 10th books of Euclid; which piece was in MS. in the library of Lord Brereton in Cheshire: as also Archimedes's Arenarius, and the greatest part of Diophantus's six books of Arithmetic; of which author he was preparing, August 1644, a new edition, in which he intended to correct the translation, and make new illustrations. He designed likewise to publish an edition of Apollonius; but laid it aside, in May 1645, at the desire of Golius, who was engaged in an edition of that author from an Arabic manuscript, given him at Aleppo 18 years before. Letters of Dr Pell to Sir Charles Cavendish, in the Royal Society.

Some of his manuscripts he left at Brereton in Cheshire, where he resided some years, being the seat of William Lord Brereton, who had been his pupil at Breda. A great many others came into the hands of Dr Busby; which Mr Hook was desired to use his endeavours to obtain for the Society. But they continued buried under dust, and mixed with the papers and pamphlets of Dr Busby, in four large boxes, till 1755; when Dr Birch, secretary to the Royal Society, procured them for that body, from the trustees of Dr Busby. The collection contains, not only Pell's mathematical papers, letters to him, and copies of those from him, &c. but also several manuscripts of Walter Warner, the mathematician and philosopher, who lived in the reigns of James I. and Charles I.

Dr Pell invented the method of ranging the several steps of an algebraical calculus, in a proper order, in so many distinct lines, with the number affixed to each step, and a short description of the operation or process in the line. He also invented the character ÷ for division, ⊕ for involution, ω for evolution *.

PELLETIER (Bertrand), was born at Bayonne in 1761, and very soon began to display an insatiable thirst of science. It frequently happens, however, that young men, sincerely desirous of instruction, have no means or place where they can be assisted in the developement of their natural talents, no master who may point out the direct road to science, and that order and method, without which the efforts of the individual too often lead him from the object of his pursuit, instead of bringing him nearer to it. This was not the case with young Pelletier. He found every advantage in his father's house, where he received the first elements of the art of which he was afterwards the ornament; and his subsequent progress was made under Darcet, who having remarked in him that sagacity which may be called the instinct of science, admitted him among the pupils attached to the chemical laboratory of the college of France. Five years of constant application and study under such a master, who was himself formed by nature, perfected by experience, and affectionately disposed towards his pupil, afforded this young man a stock of knowledge very unusual at his age. He soon gave a convincing proof of this, by publishing, at the age of 21, a set of very excellent observations on the arsenical acid. Macquer, by mixing nitre with the oxyd of arsenic, had discovered in the residue of this operation a salt soluble in water, susceptible of crystallization in tetrahedral prisms, which he denominated the neutral

* *Hutton's Mathematical Dictionary.*

arsenical salt. It is the arseniat of potash. He was of opinion that no acid could decompose it; but Pelletier shewed, that the sulphuric acid distilled from it does disengage the acid of arsenic. He shewed the true cause why the neutral arsenical salt is not decomposable in closed vessels; and particularly the order of affinity by which the salt itself is formed in the distillation of the nitrate of potash, and the white oxyd of arsenic. He explains in what respects this salt differs from what Macquer called the liver of arsenic. Pelletier had been anticipated in this work by Scheele, by Bergman, by the academicians of Dijon, and by Berthollet; but he possessed at least the merit, in the first essay of his powers, of having clearly developed all the phenomena of this operation, by retaining and even determining the quantity of gas it was capable of affording. After the same principles it was that he decomposed the arsenico-ammoniacal salt, by shewing how, in the decomposition of this last, the pure arsenical acid is obtained in the form of a deliquescent glass. In this work we may observe the sagacity with which he was enabled to develope all the phenomena of these compositions and decompositions, by tracing those delicate threads of scientific relation which connect the series of facts, and are imperceptible to ordinary minds.

Encouraged by the success of these first works, which he presented with the sensibility of grateful attachment to his instructor, he communicated his observations on the crystallization of sulphur, cinnabar, and the deliquescent salts; the examination of zeolites, particularly the false zeolite of Fribourg in Brisgaw, which he found to be merely an ore of zinc; observations on the dephlogisticated or oxygenated muriatic acid, relative to the absorption of oxygen; on the formation of ethers, particularly the muriatic and the acetous; and several memoirs on the operation of phosphorus made in the large way; its conversion into phosphoric acid, and its combination with sulphur and most metallic substances.

It was by his operations on that most astonishing production of chemistry, phosphorus, that he burned himself so dangerously as nearly to have lost his life. After the cure of his wound, which confined him to his bed for six months, he immediately began the analysis of the various plumbagos of France, England, Germany, Spain, and America, and found means to give novelty and interest to his work, even after the publication of Scheele on the same object. The analysis of the carbonat of barytes led him to make experiments on animals; which prove that this earth is a true poison, whether it be administered in the form of the native carbonat of barytes, or whether it be taken from the decomposition of the sulphat, even though again combined with another acid.

Chemists have given the name of *strontian* to a newly discovered earth, from the name of the place where it was first found. Pelletier analysed it, and discovered it in the sulphat of barytes. He likewise analysed the verditer of England, of which painters and paper-hangers make so much use. He discovered a process for preparing it in the large way, by treating with lime the precipitate obtained from the decomposition of nitrat of copper by lime. By his process, verditer is afforded equal in beauty to that which comes from England. He was likewise one of the first chemists who shewed the possibility of refining bell metal, and separating the tin. His first experiments were made at Paris; after which he repaired to the foundry at Romilly, to verify them in the large way. The following year he was received a member of the Academy of Sciences at Paris, and shortly afterwards went to La Fere, with Borda and General Daboville, to assist in experiments upon a new gunpowder. Being obliged, in order to render his experiments more decisive, to pass great part of the day in the open air during a cold and humid season, his health, which was naturally delicate, became considerably impaired. He began to recover his health, when he again became the victim of his zeal for the science he so successfully cultivated. He had nearly perished by respiring the oxygenated muriatic acid gas. A violent attack of convulsive asthma, which returned during several days, was the first consequence of this unhappy accident. The disorder then seemed to abate; but it was incurable. The assistance of art was insufficient to save him; and he died in Paris, on the 21st of July 1797, of a pulmonary consumption, in the flower of his age.

PENDULUM (See *Encycl.*). Besides the effects of heat and cold on the length of the pendulum rod, and of course on its isochronism, it may certainly be worth while, in the construction of clocks intended to measure time with the utmost possible exactness, to take into consideration the resistance of the air, which, by its unequal density, varying the weight of the pendulum, must in a small degree accelerate or retard its motion. The celebrated David Rittenhouse, who paid particular attention to this subject, estimates the extreme difference of velocity, arising from this cause, at half a second a day; and he observes, that a remedy dependent on the barometer will not be strictly accurate, as the weight of the entire column of air does not precisely correspond with the density of its base. He proposes, therefore, as a very simple and easy remedy, that the pendulum shall, as usual, consists of an inflexible rod carrying the ball beneath, and continued above the centre of suspension to an equal (or an unequal) distance upwards. At this extremity is to be fixed another ball of the same dimensions (or greater or less, according as the continuation is shorter or longer), but made as light as possible. The oscillations of this upper ball will be accelerated by its buoyancy by the same quantity as those of the lower would be retarded; and thus, by a proper adjustment, the two effects might be made to balance and correct each other.

Our author made a compound pendulum on these principles, of about one foot in its whole length. This pendulum, on many trials, made in the air 57 vibrations in a minute. On immersing the whole in water, it made 59 vibrations in the same time; shewing evidently, that its returns were quicker in so dense a medium as water than in the air. (This is contrary to what takes place with the common pendulum). When the lower bob or pendulum only was plunged in water, it made no more than 44 vibrations in a minute.

PENNANT (Thomas, Esq.), so well known in the republic of letters as a writer of travels and of natural history, was an ancient Briton by birth, having drawn his first breath in Flintshire, in 1726. His family has been settled in that county for many centuries; we learn from himself that he received the rudiments of his education at Wrexham, whence he was removed to Fulham. Soon after this he was sent to Oxford; and having

Pennant. ving made a considerable proficiency in the classics, he applied himself within the walls of that university to attain a knowledge of jurisprudence; but we do not find that he ever entered himself of any of the inns of court, or followed the law as a profession.

The ruling passions of mankind are excited, and the future current of their lives frequently directed, by trivial circumstances. One of the greatest painters of our age was attracted with an irresistible impulse towards his art by the perusal of a treatise on it; and we have the authority of the subject of this memoir for asserting, that a present of Willughby's Ornithology, at an early period, first gave him a turn for natural history, which has never once abandoned him through the course of a very long life.

Mr Pennant commenced his travels with great propriety at home, where he made himself acquainted with the manners, productions, and curiosities, of his native country, before he sallied forth to inspect those of other nations. ~~He then repaired to~~ the continent; and not only acquired considerable additional knowledge relative to his favourite studies, but became acquainted, and established a correspondence, with some of the greatest men of the age.

On his return he married, and had two children, but did not come into the family fortune until he was thirty-seven years of age, at which time he was settled at Downing.

Having lost his wife, he appears to have set out once more for the continent, and to have formed an acquaintance with Voltaire, Buffon, Haller, Pallas, &c. He had by this time acquired considerable reputation as a scientific man, having commenced his career as an author so early as 1750. His British Zoology * established his reputation as a naturalist; and this received a fresh accession of celebrity in consequence of his acquaintance with Linnæus, and his intercourse by letters with all the celebrated naturalists in Europe.

* Four vols 4to.

Early in life he had undertaken a most interesting tour to Cornwall; and he now entertained an ardent desire to survey the works of nature in the northern extremities of the island. He accordingly set out for Scotland, and in 1771 favoured the public with an entertaining account of his Tour †, which was so well received as to pass through several editions. Not content with the main land of Great Britain, he was ambitious to survey the islands in the vicinity, and accordingly penetrated to the Hebrides, and visited Man.

† Three vols 4to.

It is not to be supposed that he would leave his own country unexplored; on the contrary, he minutely described all its wonders. He did not fail on this occasion to present the world with the result of his enquiries, for in 1778 he commenced the publication of his Welch Tour §.

§ Two vols 4to.

In four years after this (1782) appeared the account of the Journey from Chester to London ‡, in which he refutes the vulgar opinion that it is uninteresting; and in two years more his Arctic Zoology, an admirable work, greatly prized both here and in other countries.

‡ One vol. 4to.

In 1790 appeared a quarto volume, simply entitled Of London; in which he observes that this work is composed from observations, originally made without any view of publication. "Let me request (says he in the preface) the good inhabitants of London and Westminster not to be offended at my having stuffed their Iliad into a nutshell; the account of the city of London and liberties of Westminster into a quarto volume. I have condensed into it all I could; omitted nothing that suggested itself; nor amplified any thing to make it a guinea book. In a word, it is done in my own manner, from which I am grown too old to depart.

"I feel within myself a certain monitor that warns me (adds he) to hang up my pen in time, before its powers are weakened, and rendered visibly impaired. I wait not for the admonition of friends. I have the Archbishop of Grenada in my eye; and fear the imbecility of human nature might produce in long-worn age the same treatment of my kind advisers as poor Gil Blas had from his most reverend patron. My literary bequests to future times, and more serious concerns, must occupy the remnant of my days. This closes my public labours."

Notwithstanding his parting address, the example of the Archbishop of Grenada, and the concluding sentence of "*Valete & Plaudite*," we find Mr Pennant adventuring once more in the ocean of literature, at a late period of his life, and trying his fortune again with all the eagerness of a young author.

He accordingly published the Natural History of the parishes of Holywell and Downing *, within the precincts of the latter of which he had resided about half a century.

* One vols 4to.

He also presented the public, a very short time before his death, with a splendid work, consisting of 2 vols. 4to. entitled The View of Hindoostan; in the preface to which he candidly states his motives for this new attempt. "I had many solicitations from private friends (says he), and a few wishes from persons unknown, delivered in the public prints, to commit to the press a part, in the form in which the posthumous volumes might hereafter make their appearance. I might have pleaded the imprudence of the attempt at my time of life, of beginning so arduous an undertaking in my 71st year.

"I happily, till very lately, had scarcely any admonition of the advanced season. I plunged into the sea of trouble, and with my papers in one hand, made my way through the waves with the other, and brought them secure to land. This, alas! is finite boasting. I must submit to the judgment of the public, and learn from thence how far I am to be censured for so grievous an offence against the maxim of Aristotle, who fixes the decline of human abilities to the 49th year.

"I ought to shudder, when I consider the wear and tear of 22 years; and feel shocked at the remark of the elegant Delanty, who observes, 'that it is generally agreed among wise men, that few attempts, at least in a learned way, have ever been wisely undertaken and happily executed after that period!'

"I cannot defend the wisdom: yet from the good fortune of my life I will attempt the execution."

These valuable volumes are drawn up by Mr Pennant in the manner of his introduction to the Arctic Zoology. The plates, 23 in number, are admirably engraved, and one (the Napaul pheasant) is beautifully coloured.

In addition to the list of literary labours already enumerated, is a letter on an earthquake felt at Downing, in Flintshire, in 1753; another inserted in the same publi-

Pennant. publication *, in 1756, on coralloid bodies (*[illegible]*) collected by him: his Synopsis of Quadrupeds, published in 1771; a pamphlet on the Militia; a paper on the Turkey; and a volume of Miscellanies.

* *Phil. Trans.*

Mr Pennant attained academical honours of all kinds, having had the degree of LL. D. conferred on him by the university in which he was educated, he was a Fellow of the Royal Society, and a member of the Society of Antiquaries, a Fellow of the Royal Society of Upsal in Sweden, a member of the American Philosophical Society, an honorary member of the Anglo-Linnæan Society, &c.

The ample fortune left him by his father enabled Mr Pennant to keep an hospitable table, and also to present the profits of several of his works to public institutions, particularly the Welsh charity-school in Gray's-inn-lane. He encouraged several engravers by his patronage, and was not a little serviceable to the advancement of the fine arts.

In 1776 he married a second time; on which occasion he became united to Miss Mostyn, sister of his neighbour, the late Sir Roger Mostyn, in Flintshire. The latter part of his life was chearful, and he scarcely felt the approaches of old age. He died at his seat at Downing in his 72d year.

He has left several works behind him in MS. under the title of Outlines of the Globe; and as a proof that it will be a very voluminous and interesting publication, it is only necessary to observe, that The View of Hindoostan composed the xivth and xvth volumes.

Mr Pennant possessed a well-compacted frame of body, an open and intelligent aspect, an active and chearful disposition, and a vivacity which rendered him always entertaining, as well in conversation as in writing. Though not without a share of irrascibility, his heart was kind and benevolent. He was exemplary in the relations of domestic life, and sensibly felt for the distresses of his poor neighbours, whose relief in seasons of hardship he promoted with great zeal and liberality. His candour and freedom from ordinary prejudices, are sufficiently displayed in his writings; and Scotland was forward to confess, that he was the first traveller from this side the Tweed, who had visited the country with no unfriendly spirit, and had fairly presented it under its favourable as well as its less pleasing aspects. As a writer, his style is lively and expressive, but not perfectly correct. His principles of arrangement in zoology are judicious, and his descriptions characteristic. If in some of his later works a little vanity appears, and a propensity to think that important to the world which was so to himself, it may readily be pardoned to one who has afforded such copious and valuable entertainment to the public. His name will live with honour in the literary history of his country, and his memory will be cherished with respect and affection by his surviving friends.

PENNATULA (See *Encycl.*). A species of this animal, hitherto undescribed, was discovered by La Martiniere near Nootka. Its body is of a cartilaginous substance, and a cylindrical form; its head, armed with two little horns of the same substance, presents a spherical figure flatted at its anterior extremity. This part is covered with small papillæ, some of which are visible at D, and which serve the purpose of small mouths, by means of which this animal sucks the blood of fishes, making its way as far as possible into the flesh: the extremity of its body, which always projects from the fish, appears like the feathers of a pen; these feather-like substances serve as excretory vessels; for on making a slight pressure on the animal, from the greater part of these cartilaginous barbs issued small drops of a very limpid liquor: at the base of these barbs, and beneath the body, are placed two large cartilaginous threads, of which our author could not imagine the use, for they are not universally met with in each individual. The circulation of its blood is readily observed, it forms a complete revolution about once in a minute. It is probable that this animal is only able to make its way into the bodies of different fish when it is very young; and when it has once buried itself there, having abundance of nourishment, its head increases considerably, and the two horns with which it is furnished necessarily form an obstacle to its regress, which is a remarkable instance of the foresight of Nature, since it is destined ~~to be nourished~~ at the expence of another. The pennatula, of which we have given from Martiniere a figure, was found by him at the depth of more than an inch and an half in the body of a *diodon*.

Plate XLI

Pepusch.

PEPUSCH (John Christopher), one of the greatest theoretic musicians of modern times, as we are told, was born at Berlin about 1667; and became so early a proficient on the harpsichord, that at the age of 14 he was sent for to court, and appointed to teach the prince, father of the late King of Prussia. About 1700, he came over to England, and was retained as a performer at Drury Lane: it is supposed that he assisted in composing the operas which were performed there. While he was thus employed, he forebore not to prosecute his private studies; and these led him to enquire into the music of the ancients, and the perusal of the Greek authors upon that subject. The abilities of Pepusch, as a practical composer, were not likely to become a source of wealth to him: his music was correct, but it wanted variety of modulation. Besides, Handel had got possession of the public ear, in the opinion of whose superior merit he readily acquiesced; and chose a track for himself, in which he was almost sure to meet with no obstruction. He became a teacher of music, not the practice of any particular instrument, but music in the absolute sense of the word, that is to say, the principles of harmony and the science of practical composition; and this, not to children or novices, but in very many instances to professors of music themselves.

In 1713, he was admitted to the degree of Doctor in Music at Oxford, and continued to prosecute his studies with great assiduity. In 1724, he accepted an offer from Dr Berkeley to accompany him to the Bermudas, and to settle as professor of music in his intended college there; but the ship in which they sailed being wrecked, he returned to London, and married Francesca Margarita de l'Epine. This person was a native of Tuscany, and a celebrated singer, who performed in some of the first of the Italian operas that were represented in England. She came hither with one Greber, a German, and from this connection became distinguished by the invidious appellation of *Greber's Peg*. Afterwards she commenced a new connection with Daniel Earl of Nottingham, who had defended the orthodox notion of the Trinity against the heretic Whiston; and to this connection Rowe, in imitation of

Horace's,

Pepusch. Horace's, "Ne sit ancillæ tibi amor pudori," thus alludes:

> Did not base Greber's Peg inflame
> The sober Earl of Nottingham,
> Of sober sire descended?
> That, careless of his soul and fame,
> To play-houses he nightly came,
> And left church undefended.

She continued to sing on the stage till about 1718; when having, at a modest computation, acquired above ten thousand guineas, she retired from the theatre, and afterwards married Dr Pepusch. She was remarkably tall, and remarkably swarthy; and, in general, so destitute of personal charms, that Pepusch seldom called her by any other name than Hecate, to which she is said to have answered very readily.

The change in Pepusch's circumstances by Margarita's fortune was no interruption to his studies: he loved music, and he pursued t[illegible]owledge of it with ardour. At the instance of Gay an[illegible]ich, he undertook to compose, or rather to correct, the [illegible] for the Beggar's Opera. His reputation was now at a great height. He had perused with great attention those several ancient treatises on Harmonics, published by Meibomius, and that of Ptolemy by Dr Wallis; and the difficulties which occurred to him on the perusal, were in a great measure removed by his friend De Moivre the mathematician, who assisted him in making calculations for demonstrating those principles on which the harmonic science is founded. In consequence of these studies, he was esteemed, in matters of theory, one of the best musicians of his time. In 1737, he was chosen organist of the Charter-house, and retired, with his wife, to that venerable mansion. The wife died in 1740, before which he lost a son, his only child; so that he had no source of delight left, but the prosecution of his studies, and the teaching of a few favourite pupils, who attended him at his apartments. Here he drew up that account of the ancient genera which was read before the Royal Society, and is published in the Philosophical Transactions for October, November, and December, 1746; and, soon after the publication of that account, he was chosen a Fellow of the Royal Society.

He died the 20th of July, 1752, aged 85; and was buried in the chapel of the Charter-house, where a tablet with an inscription is placed over him *.

PERCUSSION, Force of Percussion, is the name by which mechanicians distinguish that faculty of producing motion, or making other sensible mechanical impressions on bodies, by means of the stroke of a body in motion. It is nearly the same with *impul[illegible]* only, it would seem that the very scrupulous and refined affect to limit the attention to the *immediate* cause of the motion, or other effect produced; to the something that is different, both from the force supposed to be inherent in the moving body (a hammer for example), and the subsequent motion and penetration of the nail which is driven by it. We may venture to say that it is needless to attempt any investigation of this object. It is hid, with all other causes of all other effects in the universe, in impenetrable darkness. If we reflect on the constitution of our own mind, so far as we can know it by experience and observation, and on the manner in which we draw conclusions, we must see that the knowledge of the efficient cause of any effect is unattainable; for were the intervening something pointed out to us, and clearly conceived by us, we should find it just as necessary to find out why and how this something is connected with each of the events which we observe it invariably to connect. Percussion.

But a knowledge of the force of percussion, in as far as it may or may not be distinguishable from other forces, is not unattainable. We can learn as much, and no more, concerning this, as concerning any other force; and we can contemplate that circumstance which, in our opinion, is common to it with all other forces, and may perhaps discover other circumstances in which it differs from them. But in all this disquisition, it is plain that it is only events, which we conceive to be the characteristic effects of the cause, that we contemplate.

Percussion, considered as an effect, characteristic of a particular faculty of moving bodies, became an object of anxious research, almost as soon as philosophers began to think of motion and moving forces at all. The ancients (as has been observed in the article Impulsion, *Suppl.*) contented themselves with very vague speculations on the subject. Galileo was the first who considered it as a measurable thing, the object of mathematical discussion; being encouraged by his precious discovery of the laws of accelerated motion, and the very refined measure which these gave him of the power of gravity. It was a measure of the heaviness, not of the weight, of the body; and this was measured by its acceleration, and not by its pressure. Encouraged by this, he hoped to find some such measure of the force of percussion, which he saw so intimately connected with motion; whereas its connection with pressure was far from being obvious. He therefore tried to convert the terms; and as he had found a measure of the pressure of gravity in the acceleration of motion, he endeavoured to find in pressure a measure of the force of percussion arising from this acceleration. He endeavoured to find the number of pounds, whose pressure is equal to the blow of a given body, moving with a given velocity. The velocity was known to him with great precision, by means of the height from which the ball must fall in order to acquire it. It seems pretty clear that percussion may be measured in this way; for a body falling from a height will pierce an uniformly tenacious body to a certain degree, and no further; and experiment shews that this degree of penetration is very precise and constant. The same body, being merely laid on the tenacious body, will penetrate to a small depth by its weight. Laying more weight on it, will make it penetrate deeper; and a certain weight will make it penetrate as deep as the fall did, and no deeper. Thus, percussion seems very easily measurable by weight, or by any pressure similar to that of weight. It appears that Galileo made experiments with this view, and that he was disappointed, and obliged to acquiesce in the opinion of Aristotle, that percussion and weight are incomparable. He proposes, therefore, another experiment, namely, to drop a body into the scale of a balance from greater and greater heights, till at last the blow on the scale raises a weight that lies in the other scale. This offers itself so plausibly, that we are persuaded that Galileo tried it: but as he makes no men-

 tion

Percussion. tion of the results, we presume that they were unsatisfactory.

Neither of these experiments *could* give us a measure of the force of percussion, if this force be any thing different from the forces which are excited or brought into action by percussion, in the manner described in the article IMPULSION, *Suppl.* When the ball comes into physical contact with the scale, it begins to compress it. This compression begins to stretch the strings by which the scale is supported. These pull at the arm of the balance, and cause it to press the centre-pin a little harder on its support, and to bend the balance a little, and cause it to pull at the cords which support the other scale. That scale is pulled upwards, diminishing a little its pressure on the ground, and pressing it harder to the incumbent weight. These forces are excited *in succession* from the one scale to the other, and a small moment of time elapses. The reaction of the scale diminishes, but does not instantaneously annihilate, the velocity of the falling ball. It therefore compresses the scale still more, stretches the threads, presses the fulcrum, and bends the balance still more (because the weight in the other scale keeps it down). The velocity of the falling ball is rapidly diminished; the balance is more bent, and pulls more strongly upwards at the threads of the other scale; and thus presses that scale more strongly against the incumbent weight, gradually communicating more and more motion to it, removing it farther from the ground, till, at last, the motion becomes sensible, or so considerable as to disengage some delicate catch as a signal. The experiment is now finished; and the mechanician fondly thinks that, at this instant, the pressure excited by the percussion, between the opposite scale and the under side of the incumbent weight, is just equal, or but a very little superior, to the pressure of the incumbent weight: and, since the arms of the balance are equal, and therefore the pressures on the two scales are equal, he imagines that that weight exerts a pressure equal to the percussion of the falling ball.

But all this is misconception, and also false reasoning. It is not percussion that we are measuring, but the pressures, excited by percussion, on the two scales. And these pressures are the forces of elasticity or expansiveness, belonging to, or inherent in, the particles of the balls and the scales; forces which are brought into action by the approach of those bodies to each other. This reasoning is also erroneous; and we should be mistaken if we think that the pressure actually exerted is equal to that of the weight in the opposite scale. It is greater than the mere pressure of that weight. The reaction of the opposite scale on its load was precisely equal to that weight before the ball was dropped from the hand; and, had the ball been equal to that weight, and simply laid into the scale on which it falls, it would have made no change on the mutual pressures of the scale and the other weight; it would only have relieved the ground from the pressure of that weight, and would have brought it on the threads which support its scale. The pressure of this scale upwards must be increased, before it can start the weight sensibly from the ground. How much it must be increased depends on the springiness of the scales, cords, and beam. By a proper adjustment of these particulars, the apparatus will give us almost any measure of percussion that we choose. For this reason, the improvements made on it by Gravesande are of no value. The same reasoning, nearly, may be applied to the measurements of the force of percussion by means of the penetration of soft bodies. Percussion.

Galileo mentions another very curious experiment, by which he thought that he had obtained a just measure of percussion. A vessel, filled with water, was suspended on the arm of a balance, with another vessel hanging from it, a great way below. All was exactly balanced by a weight in the opposite scale. By means of a suitable contrivance, a hole was opened in the bottom of the upper vessel, without disturbing the equilibrium. As soon as the water issued, and while it was falling through the air, that end of the balance rose; but when the water struck the lower vessel, the equilibrium was restored, and continued during the whole time of the efflux. Hence Galileo concluded, that the force of the stroke was equal to the weight of the falling water. But we apprehend that the observations made on this in the article IMPULSION, *Suppl.* will convince the reader that this conclusion is far from being legitimate. Besides, the stroke, in any one instant, is made by those particles only which strike in that instant, while the whole vein of water between the vessels is neither acting by its weight on the upper vessel, nor by its stroke on the lower; and we should conclude from the experiment, that the force of percussion is infinitely greater than the weight of the striking body. Indeed this is the inference made by Galileo. But if we have recourse to the experiments and reasonings of Daniel Bernoulli, in the article *RESISTANCE of Fluids*, *Encycl.* we shall find that the seeming impulse on the lower vessel is really a most complicated pure pressure, and of most uncertain determination. The experiment is valuable, and gives room for curious reflections. We have repeated it, in a great variety of forms, and with great changes of impulse, and sometimes in such a manner that no impulse whatever can obtain, while at the same time a quantity of water was falling, unsupported by either vessel. In all the trials the equilibrium remained undisturbed. We were obliged to conclude, therefore, that the experiment afforded no measure of percussion. Indeed we were of this opinion before making the trial, for the reasons just now given.

We cannot say that the subsequent labours of philosophers have added much to our knowledge of this matter. Mr Leibnitz had contrived his whimsical doctrine of *living* and *dead* forces. The action of gravity, or of a spring, is a *vis viva*, when it actually produces motion in the body on which it acts: but when a stone lies on a table, and presses on it, this pressure is a *vis mortua*. Its exertion is made, and in the same instant destroyed, by an opposite *vis mortua*. Each of these exertions would have produced *a beginning* of motion (something different from any the smallest local motion); and the sum of all would, after a certain time, have amounted to a sensible motion and velocity. There seems no distinct conception to accompany, or that can accompany, this language. And, as a proof that Leibnitz had no distinct conceptions of the matter, he has recourse to this very experiment of Galileo in support of his genesis of a sensible motion from the continual exertions of the *vis mortua*; and he concludes that the force of percussion is infinitely, or incomparably, greater than pressure, because it is the sum total of an infinity of individual

dual exertions of *vis mortua*. Nothing but the authority which Leibnitz has acquired on the continent, by the zealous efforts of his partizans, could excuſe our taking up any time in conſidering this unintelligible diſcourſe. Surely, if there is ſuch a thing as a *vis viva*, it exiſts in the moving water, and its impulſions are not continual exertions of a *vis mortua*. Nor is it poſſible to conceive continual impulſe, nor a beginning of motion that is not motion, &c. &c. It is paradoxical (and Leibnitz loved to raiſe the wonder of his followers by paradoxes) to ſay that percuſſion is infinitely greater than preſſure, when we ſee that preſſure can do every thing that can be done by percuſſion. Nay, Euler, by far the moſt able ſupporter of the doctrines of Leibnitz about the force of bodies in motion, actually compares theſe two forces; and, in his Commentary on Robins's Artillery, demonſtrates, in his way, that when a muſket ball, moving with the velocity of 1700 feet per ſecond, penetrates five inches into a block of elm, the force of its percuſſion is [illegible]760 times its weight. John Bernoulli reſtricts the infinite magnitude of percuſſion to the caſe of perfectly hard bodies; and, for this reaſon alone, ſays, that there can be none ſuch in the univerſe. But, as this juſtly celebrated mathematician ſcouts with ſcorn the notion of attractions and repulſions, he muſt allow, that an ultimate atom of matter is unchangeable in its form; which we take to be ſynonymous with ſaying that it is perfectly hard. What muſt be the reſult of one atom in motion hitting another at reſt? Here muſt be an inſtantaneous production of a finite velocity, and an infinite percuſſion. A doctrine which reduces its abettors to ſuch ſubterfuges, [illegible] the mind in ſuch puzzling contemplations, cannot (to ſay the beſt of it) be ſtyled an EXPLANATION of the laws of Nature. The whole language on the ſubject is full of paradoxes and obſcurities. In order to reconcile this infinite magnitude of percuſſion with the obſerved finite magnitude of its effects, they ſay that the preſſure, or inſtantaneous effort, has the ſame relation to the force of percuſſion that an element has to its integral; and in maintaining this aſſertion, they continually conſider this integral under the expreſs denomination of a *ſum total*, robbing Leibnitz's great diſcovery of the infiniteſimal calculus of every ſuperiority that it poſſeſſed over Wallis's Arithmetic of Infinites, and really employing all the erroneous practices of the method of indiviſibles. We look upon the ſtrange things which have been inculcated, with pertinacious zeal, in this doctrine of percuſſion and *vires vivæ*, as the moſt remarkable example of the errors into which the unguarded uſe of Cavalerius's Indiviſibles, and of the Leibnitzian notion of the infiniteſimal calculus, have led eminent mathematicians. It is not true that the preſſure, and the ultimate force of percuſſion, have this relation; nor has the preſſure and the reſulting motion, which is miſtaken for the meaſure of this ultimate force, any mathematical relation whatever. The relation is purely phyſical; it is the relation of pure cauſe and effect; and all that we know of it is their conſtant conjunction. The relation of fluxion and fluent is not a mathematical or meaſurable relation, but a connection in thought; which is ſufficient for making the one an indication of the other, and the meaſures of the proportions of the one a mean for obtaining a meaſure of the proportions of the other. In this point of view, the relation of preſſure to motion, as the meaſure of the force of percuſſion, *reſembles* that of fluxion and fluent, but is not the ſame. Percuſſion.

Much has been ſaid by the partizans of Mr Leibnitz about the incomparableneſs of preſſure and percuſſion, and many experimental proofs have been adduced of the incomparable ſuperiority of the latter. Bulfinger ſays, that the preſſure of many tons will not cauſe a ſpike to penetrate a block of hard oak half ſo far as it may be driven by a weak man with [illegible] of a mallet; and that a moderate blow with a ſmall hammer will ſhiver to powder a diamond, which would carry a mountain without being hurt by its preſſure. Nay, even Mr Camus, of the Academy of Paris, a ſtaunch Carteſian, and an eminent mechanician, ſays that he beat a leaden bullet quite flat with a hammer of one pound weight, without much force; and that he found that 2[illegible] pounds weight would not have flattened it more than this blow: and he concludes from thence, that the force of the blow exceeded 200 pounds. Theſe, to be ſure, are remarkable facts, and juſtify a more minute conſideration of a power of producing certain effects, which is ſo frequently and ſo uſefully employed. But, at the ſame time, theſe are all very vague expr[illegible]s, and they do not authoriſe any preciſe concluſi[illegible] from them. Mr Camus ſaying "without much force," makes his pound weight, and his 200 pound weight, of no uſe [illegible] determining the force of the blow. He would have given more preciſe and applicable data for his deciſion, had he told us from what height the hammer ſhould fall in order to flatten the bullet to this degree. But even then we ſhould not have obtained any notion of the force in actual exertion during the flattening of the bullet; for the blow which could flatten the bullet in a longer or a ſhorter time, would unqueſtionably have been leſs or greater.

All the paradoxes, obſcurities, and puzzling difficulties, in this ſubject diſappear, if we leave out of our conſideration that unintelligible force, which is ſuppoſed to preſerve a body in motion or at reſt; and if we conſider both of theſe ſtates of body as conditions which will continue, unleſs ſome adequate cauſe operate a change; and if we farther grant, that ſuch cauſes do really exiſt in the univerſe, however unknown their nature may be by us; and, laſtly, if we acknowledge, that the phenomena of elaſticity, expanſiveneſs, coheſion, gravity, magnetiſm, electricity, are indications of the agency of ſuch cauſes, and that their actual exertions, and the motions and changes conſequent on theſe exertions, are ſo invariably connected with particular bodies, that they always accompany their appearance in certain mutual relations of diſtance and poſition:—if we proceed thus, all the phenomena of colliſion will be explained by theſe cauſes alone, without ſuppoſing the exiſtence and agency of a cauſe diſtinct from them all, and incomparable with them, called the FORCE OF PERCUSSION.

For it has been ſufficiently demonſtrated in the article IMPULSION (*Suppl.*), that that property of tangible coherent matter, which we call *perfect elaſticity*, operates as a preſſure during a certain ſmall portion of time on both bodies, diminiſhing more and more the motion of the one, and augmenting that of the other, as the compreſſion of one or both increaſes, till at laſt they ſeparate with ſenſible velocities. In ſome very ſimple or perſpicuous

 spicuous cases, we know what this pressure is in every instant of the action. We can tell how many pounds weight, at rest, will exert the same pressure. We can tell the whole duration of this pressure, and the space along which it is exerted; and, in such a case, we can say with precision what motion will be generated by this continued and varied pressure on the body which was at rest, and what diminution will be made in the motion of the other. All this can be done in the case of a ball A (fig. 1.), moving like a pendulum with a small velocity, and striking a slender elastic hoop B, also suspended like a pendulum. We can ascertain by experiment, before the collision, what pressure is necessary for compressing it one inch, one-half, one-fourth, &c. Knowing this, and the weight of the hoop, and the weight and velocity of the ball, we can tell every circumstance of the collision—how long the compression continues—what is the greatest compression—how far the bodies have moved while they were acting on each other—and what will be the final motion of each:—in short, every thing that affords any mark or measure of a force of percussion. And we know that all this is produced by a force, familiarly known to us by the name of elasticity. Which of all these circumstances shall be called the percussion, or the force of percussion? Is it the ultimate or greatest pressure occasioned by the compression? This cannot be, because this *alone* will not be proportional to the final change of motion, which is generally taken as a measure of the percussion when a change of motion is its only observed effect.

Plate XLI

We know that another perfectly elastic body, of the same weight, and struck by the same blow, and acquiring the same final velocity by the stroke, may not have sustained the tenth part of the pressure, in any one instant of the collision, if it has only been much more compressible. The greatest mutual pressure in the collision of a billiard ball is perhaps 1000 times greater than it is in a similar collision of a foot-ball of the same weight.

We also know what degree of compression will break this hoop, and what pressure will produce this compression. Therefore, should the fracture of the body be considered as the mark and measure of the percussion, we know what blow will just produce it, and be exhausted by so doing. In short, we know every mark and measure of percussion which this hoop can exhibit.

We can increase the strength of this hoop till it becomes a solid disk; and we see clearly, that in all these forms the mode of acting is the same. We see clearly that it is the same when, instead of the solid disk, it is an elastic ball; therefore every thing that can indicate or measure the percussion of an elastic ball, is explained without the operation of a peculiar force of percussion, even when the ball is shivered to pieces by the blow.

Nor is the case materially different when the bodies are soft, or imperfectly elastic. When the struck body is uniformly tenacious, it opposes a uniform resistance to penetration, and its motion will be uniformly accelerated by the action of its own tenacity during the whole time of mutual action, except a trifling variation occasioned by the mere motion of the internal parts, independent of their tenacity. If we knew the weight necessary for merely penetrating this mass, and the weight and velocity of the penetrating body, we can tell how long it must be resisted by this force before its initial velocity will be annihilated, and therefore how far it will penetrate. We have tried this with deal, birch, willow, and other soft woods of uniform texture, and with nails having the body somewhat slenderer than the end, that there might not be an irregularity occasioned by a friction on the sides of the nail, continually increasing as the penetration advanced. We made the hammer fall from a considerable height, and hit the nail with great accuracy in the direction of its length, by fixing it to the end of a long lath, moveable round an axis. The results corresponded with the calculation with all the precision that could be desired.

But it does not result from all this agreement, that the force, exertion, or effect, of a blow with a hammer is equal to the pressure of any number of pounds whatever. They are things that cannot be compared; and yet the force operating in the penetration by a blow is no way different from a pressure. It is a physical blunder to compare the ~~area of the curve~~, whose abscissa is the depth of penetration, and the ordinates are as the resistances, with any pressure whatever. This area expresses the square of a velocity, and its slips, bounded by parallel ordinates indefinitely near each other, are as the decrements of this square of a velocity, occasioned by a pressure, acting almost uniformly along a very small space, or during a very small time. It is an absurdity therefore to sum up these slips as so many pressures, and to consider the sum total as capable of expressing any weight whatever. Such a paralogism is peculiar to Leibnitz's way of conceiving his infinitesimal method, and it could have no place in the genuine method of fluxions. It is this misconception that has made Mr Leibnitz and his followers suppose that a body, accelerated by gravity, retains in it a sum total of all the pressures of gravity accumulated during its fall, and now forming a *vis viva*. Supposing that it requires a pressure of twenty pounds to press a six pound shot slowly through a mass of uniformly resisting clay; this pressure would carry it from the top to the bottom of a mountain of such clay. Yet this ball, if discharged horizontally from a cannon, would penetrate only a few yards, even though the clay should resist by tenacity only, independent of the motion lost by giving *motion* to its internal parts. In this experiment, the utmost pressure exerted during the motion of the ball did not much exceed the pressure of twenty pounds. In this comparison, therefore, percussion, so far from appearing infinitely greater than pressure, would appear much less. But there is perhaps no body that resists penetration with perfect uniformity, even though uniformly tenacious. When the ball has penetrated to some depth, the particles which are before it cannot be so easily displaced, even although they had no tenacity, because the particles adjoining are more hemmed in by those beyond them. We have always observed, that a ball impelled by gunpowder through water rises toward the surface (having entered horizontally through the side of the vessel at some depth), and this so much the more rapidly as it entered nearer to the surface. The reason is plain. The particles which must be displaced before the ball, escape more easily upwards than in any other direction. It is for this reason chiefly that a greater weight laid on the head of a nail will cause it sink deeper into the wood; and thus a great weight appears

to be commensurable with a great force of percussion. Also, while a bullet is flattening more and more under a hammer during the progress of a blow, it is spreading under the hammer; more particles are resisting at once, and they find more difficulty in effecting their escape, being harder squeezed between the hammer and the anvil. The same increased resistance must obtain while it is flattening more and more under the quiet pressure of a weight; and thus, too, a greater weight appears to be commensurable with a greater blow.

After all, however, a blow given by a falling body must excite a pressure greater than its mere weight can do, and this in any degree. Thus, suppose AB (fig. 2.) to represent a spiral spring in its natural unconstrained dimensions, standing upright on a table. Let $a\,b$ be the abscissa of a line $a\,d\,h\,k$, whose ordinates $c\,d$, $g\,h$, $i\,k$, &c. are as the elastic reaction of the spring when it is compressed into the lengths $c\,b$, $g\,b$, $i\,b$, &c. Suppose that, when it is compressed into the form CD, it will just support the weight of a ball lying on C. Then $c\,d$ will be a reaction equal to the weight of the ball, and the rectangle $a\,c\,d\,f$ will express the square of the velocity which this ball would acquire by falling freely through $a\,c$. If therefore the ball be gently laid on the top of the spring at A, and then let go, it will descend, compressing the spring. It will not stop when the spring has acquired the form CD, which enabled it to carry the weight of the ball gently laid on it. For in this situation it has acquired a velocity, of which the square is represented by the figure $a\,d\,f$ (See Dynamics, *Suppl.* n° 95.). It will compress the spring into the length $g\,b$, such that the area $c\,g\,h\,d$ is equal to the area $a\,d\,f$. If the ball, instead of being gently laid on A, be dropped from M, it will compress the spring into such a length $i\,b$, that the area $a\,i\,k$ is equal to the rectangle $m\,c\,d\,n$; and, if the spring cannot bear so great compression, it will be broken by this very moderate fall.

Thus we see that a blow may do things which a considerable pressure cannot accomplish. The accounts which are given of these remarkable effects of percussion, with the view of impressing notions of its great efficacy, are generally in very indefinite terms, and often without mentioning circumstances which are accessory to the effect. It would be very unfair to conclude an almost infinite power of percussion, from observing, that a particle of sand, dropped into a thick glass bottle which has not been annealed, will shiver it to pieces. When Mr Bulfinger says that a moderate blow will break a diamond which could carry a mountain, he not only says a thing of which he cannot demonstrate the truth, and which, in all probability, is not true; but he omits noticing a circumstance which he was mechanician enough to know would have a considerable share in the effect. We mean the rapidity with which the excited pressure increases to its maximum in the case of a blow. In the experiment in question, this happens in less than the millionth part of a second, if the velocity of the hammer has been such as a man would generate in it by a very moderate exertion. For the blow which will drive a good lath nail to the head in a piece of soft deal with an ordinary carpenter's hammer, must be accounted moderate. This we have learned by experiment to be above 25 feet per second. The connecting forces exerted between the particles of the diamond may not have time sufficient for their excitation in the remote parts, so as to share the derangement among them all, in such a manner that it may be so moderate in each as not to amount to a disunion in any part of the diamond. We see many instances of this in the abrupt handling of bodies of tender and friable texture. It is partly owing to this that a ball discharged from a pistol will go through a sheet of paper standing on edge without throwing it down, which it would certainly do if thrown at it by the hand. The connecting forces, having time to act in this last case, drag the other parts of the paper along with them, and their union is preserved. Also, when a great weight is laid on the diamond, it is gradually dimpled by it; and thus inclosing many parts together in the dimple, it obliges them to act in concert, and the derangement of each is thus diminished.

We flatter ourselves that the preceding observations and reflections will contribute somewhat towards removing the paradoxes and mysteries which discredit, in some degree, our mechanical science. If we will not pertinaciously conjure up ideal phantoms, which, perhaps, *cannot* exist, but content ourselves with the study of that tangible matter which the Author of Nature has presented to our view, we shall have abundant employment, and shall perceive a beautiful harmony thro' the whole of natural operations; and we shall gradually discover more and more of those mutual adaptations which enable an atom of matter, although of the same precise nature wherever it is found, to act such an unspeakable variety of parts, according to the diversity of its situations and the scene on which it is placed. If a mind be "not captivated by the harmony of such sweet sounds," we may pronounce it "dark as Erebus, and not to be trusted"

PERFECT Number, is one that is equal to the sum of all its aliquot parts when added together. Eucl. lib. 7, def. 22. As the number 6, which is $= 1 + 2 + 3$, the sum of all its aliquot parts; also 28, for $28 = 1 + 2 + 4 + 7 + 14$, the sum of all its aliquot parts. It is proved by Euclid, in the last prop. of book the 9th, that if the common geometrical series of numbers 1, 2, 4, 8, 16, 32, &c. be continued to such a number of terms, as that the sum of the said series of terms shall be a prime number, then the product of this sum by the last term of the series will be a perfect number.

PERGUNNA, in Bengal, the subdivision of a district.

PERKINISM, the proper name of what we must think an imposition attempted to be put upon the world by Dr Perkins of North America.

Though the phenomena of electricity had been long familiar to the philosophers of Europe, it is well known that a philosophical theory of these phenomena was first formed by a transatlantic philosopher. In like manner, though the discovery of Galvani, under the name of *animal electricity* (see Galvanism in this *Supplement*), had occupied the attention of many of the first physicians and philosophers of the old world, it was reserved for a physician of the new, to apply it to the cure of a number of diseases. Every philosopher of America, however, has not the sagacity of the Philadelphian sage; nor must Dr Perkins or his admirers be surprised, if we treat not incomprehensible mysticism with the respect due to a theory founded on facts.

Perkinism.

We are told by the son (A) of this rival of Franklin, that before the news of Galvani's discovery had reached America, he had observed several phenomena pointing out the influence of metals in cases of pain. The first remarkable incident that presented itself to his notice was the sudden contraction of a muscle when he was performing a chirurgical operation. This, he observed, regularly took place whenever the point of the metallic instrument was put in contact with the muscle. Struck with the *novelty* of the appearance (Is Mr Perkins sure that the appearance was new?), he was induced to try the points of wood and other substances; and no contraction taking place on these experiments, he thence inferred that the phenomena could be ascribed only to the influence of the metal. About the same time, he observed that, in one or two cases (and if his practice had been great he might have observed that in a thousand cases), a cessation of pain had ensued when a knife or lancet was applied to separate the gum from a tooth previous to extracting it; and in the same year he discovered, that *momentary* ease was given, in a few instances, by the accidental application of a metallic instrument to inflamed and painful tumors previous to any incision.

These are the judicious reasonings and assertions of a dutiful child, who, having probably heard of Leibnitz's claims to some of Newton's discoveries, was determined to put in a similar claim for his father, to a *share*, at least, of the discovery made by the celebrated professor at Bologna. He has not, however, copied with servility the conduct of the Leibnitzians. We do not remember an instance where any of them attempted to elevate the fame or the merits of their master *above* the fame and merits of Newton; but, according to our author, the pursuits of Galvani and his European pupils sink into insignificance, when compared with those of the transatlantic physician.

This is evident; for when the physiologists of Europe were engaged in experimenting on the denuded nerves and muscles of the smaller animals, with a view to ascertain the agency of this incomprehensible property in them, Dr Perkins was prosecuting a series of experiments, which consisted in applying externally, to parts affected with disease, metals, and compounds of metals of every description which occurred to him, and constructed into various forms and sizes. The result proved, that on drawing lightly over the parts affected certain instruments, termed *tractors*, which he formed from metallic substances into pointed shapes, he could remove most of those topical diseases of the human body, where an extra degree of nervous energy or vital heat was present; unless such disease was situated in some of the internal viscera, too remote from the part where the instruments could be applied.

The diseases which have been found most susceptible of the influence of the tractors are, rheumatism, some gouty affections, pleurisy, ophthalmias, erysipelas, violent spasmodic convulsions, as epileptic fits and the locked jaw, the pain and swelling attending contusions, inflammatory tumors, the [illegible] from a recent sprain, the painful effects of a burn or scald, pains in the head, teeth, and indeed most kinds of painful topical affections, excepting where the organic structure of the part is destroyed, as in wound[s,] ulcers, &c. and exc[epting] also where oils or some other non conducting substances are present.

But we have other testimonies than those of Dr Perkins and his son for the influence of the tractors. Mr Meigs, professor of natural philosophy at Newhaven, in a letter on Dr Perkins's discovery, conceives the principles of metallic irritability as so little understood, that he will not pretend to explain how the tractors produce their effects; but seems satisfied in finding that the effects are produced. After stating an experiment on his own child, eight years of age, very dangerously ill with a peripneumonic complaint, and to which the tractors gave almost instantaneous relief, he say[s], "I have used the tractors with success in several other cases in my own family; and although, like Naaman the Syrian, I cannot tell why the waters of Jordan should be better than Abana and Pharpar, rivers of Damascus; yet, since experien[ce] has proved them so, no reasoning can change the opinion. Indeed, the causes of all common facts are, *we think*, perfectly well known to us; and it is very probable, fifty or an hundred years hence, we shall as well know why the metallic tractors should in a few minutes remove violent pains, as we now know why cantharides and opium will produce opposite effects: viz. we shall know but *very little* about either, excepting *facts*."

Mr Woodward, professor of natural philosophy at Dartmouth, in a letter also on the same subject, has stated a number of successful experiments in pains of the head, face, teeth, and in one case of a sprain.

Dr Vaughan, a member of the Philadelphia medical society, has lately published an ingenious tract on Galvanism, the object of which is to account for the influence of the tractors in removing diseases. After a citation of numerous experiments made on the nerves and muscles of animals, he observes, "If we only take an impartial view of the operations of Nature herself, and attend diligently to the analytical investigations of the aforementioned experimentalists on this sublime subject, I think the sceptic must admit that the principle of nervous energy is a modification of electricity. As sensation is dependant on this energy, a pleasurable sensation, or what may be termed a natural or healthy degree thereof; then certainly pain, or supersensation, can only depend on an accumulation of the electric fluid, or extra degree of energy in the part affected. On this principle the problem admits of easy solution; namely, that the metals, being susceptible of this fluid, conduct the extra degree of energy to parts where it is diminished, or out of the system altogether, restoring the native law of electric equilibrium."

We trust we are not sceptics; and yet we feel not ourselves inclined to admit any part of this theory. We have seen no proof that nervous energy is a modification of electricity; and we think that we have ourselves proved, that *galvanism* and *electricity* are in many respects different; but we shall not be much surprised if we soon see a *demonstration* by some American or German philosopher,

(A) See a pamphlet, entitled The Influence of Metallic Tractors on the Human Body, &c. by Benjamin Douglas Perkins, A. M. son to the discoverer; or a very good abridgement of it in the first volume of the Philosophical Magazine.

rkinifm philofopher, that the foul of man is a compofition of filver and zinc. One of thefe fages has lately difcovered, that the fymptoms of *putrefaction* do not conftitute an *infallible* evidence of death, but that the application of *metals* will in all cafes afcertain it beyond the poffibility of doubt! A proper application certainly will; for when the Perkinift is doubtful whether his patient be dead or alive, he has only to apply the muzzle of a loaded piftol to his temple, and blow out his brains; after which he may fafely fwear that the man is dead.

From the *Philofophical Magazine*, we learn that Profeffor Schumacher at Copenhagen made experiments with tractors of brafs and iron on ten patients in Frederick's hofpital at Copenhagen. He tried alfo tractors of ebony and ivory, which are faid to have cured a pain in the knee; with others of filver and zinc; and fome of copper and lead. By the two laft, pains in the knee, arm, and face, are faid to have been mitigated. According to M. Klingberg's experiments, this remedy was of ufe in *malum ifchiaticum;* and according to thofe of M. Steffens, in *malum ifchiaticum* and megrim. According to M. Bang, the pains in fome cafes were increafed, and in others allayed. According to M. Blech, the tractors were of ufe in *hemicrania* and gouty pains in the head; and, according to M. Hahn, in rheumatic pains in both fhoulders. The principal

ifm, appears to be a letter of Profeffor Abilgaard, in whofe opinion Perkins's tractors will never acquire much value in medicine, and fcarcely even have the merit of being a palliative; but, in a phyfical point of view, he thinks they deferve the attention of phyficians, and particularly of phyfiologifts. Mankind (he fays) hitherto have paid too little attention to the influence which electricity has on the human body; otherwife they would know that the effects produced on it by our beds is no matter of indifference. If the feather beds and hair mattreffes, &c. are perfectly dry, the perfon who fleeps on them is in an infulated ftate; but the contrary is the cafe if they are moift. He three times removed a pain in the knee, by fticking the tractors, one on each fide of the knee, fo deep through the ftockings that the points touched the fkin. He removed a rheumatic pain in the head from a lady by the fame means. M. Kafn, by the tractors, relieved, in others, gouty pains of the head and megrim; and in himfelf, a rheumatic pain of the back, which, according to his fenfations, was like a conftriction in the cellular tiffue. M. Herholdt, from his experiments, confiders the effect of the tractors as indefinite and relative as that of other remedies. He, however, faw relief given by them in the ftrangury in a cafe of fyphilis. M. Bang alfo, at Soroe, freed a man from a violent gouty pain in the thigh, by drawing the tractors 200 times over the affected part. M. Jacobfen likewife found benefit derived from thefe tractors feveral times in the common hofpital at Copenhagen. M. Tode tried them alfo in rheumatic pains, tooth-ache, and inflammation of the eyes; and obferved that they neither did good nor harm.

On fome of the attefted cures mentioned in Mr Perkins's pamphlet, an able writer in the Monthly Review has made remarks fo very pertinent, that we cannot refufe ourfelves the pleafure of tranfcribing them.

" At page 54 of the pamphlet, we meet (fays the reviewer) with a ftrong proof of the confidence placed in this remedy by feveral tranfatlantic philofophers. Dr Willard, it feems, applied a red hot piece of iron to a wart on his finger, and burnt himfelf very feverely, in order that he might be relieved by the tractors; which are faid to have given him eafe in two fucceffive experiments. The author adds, 'many have fubmitted to fimilar meafures, in order to *experience* the effects. I once formed one of five, who burned ourfelves fo that blifters were raifed, to make the experiment; we all obtained relief in a few minutes.'

" This zeal for knowledge is truly edifying, efpecially as the tractors are generoufly prefented to the public at *only* five guineas a pair; and it is clear that one pair would fuffice to cure all the burns and fcalds of a large parifh. Why are not fuch luculent experiments repeated here? If Mr Perkins, or any admirers of the difcovery, would fubmit to have a red hot poker run into fome part of his body not neceffary to life (into *that part where honour's lodged*, according to Butler, for example), in any public coffee houfe within the bills of mortality, and would afterward heal the wound in prefence of the company, in ten minutes, or in half as many hours, by means of the tractors, the moft ftony-hearted infidel could not refift fuch a demonftration. Why trifle with internal inflammations, when fuch an outward and vifible fign might be afforded?

" Mr Perkins has taken fome pains, in the firft part of his pamphlet, to fhew that the operation of his rods is not derived from animal magnetifm. In our opinion, this is an unneceffary piece of trouble in England, where there is a conftant fucceffion of fimilar pretenfions. The *virgula divinatoria*, juggler, are the genuine prototypes of this myft... We were, indeed, rejoiced, on Dr Perkins's account, find that the Connecticut Society had only denounc... him as a Mefmerift: we trembled left he fhould have b... put into the inquifitorial hands of the old women a... white witch."

This may be thought too ludicrous a treatment of difcovery which profeffes to benefit mankind; but to have treated this difcovery with ferioufnefs, would have degraded the profeffion of a fcientific critic. As if the very cures pretended to have been performed did not of themfelves throw fufficient ridicule over the difcovery, Mr Perkins informs us, " that in fome inftances the metallic influence, when excited by different perfons, produces different effects. Experiments made to afcertain the point, proved that there were perfons who might ufe the tractors for any length of time, in difeafes which were fuitable for the operation, and produce no perceptible effect; when by placing them the hands of another perfon, who fhould perform the operation precifely in the fame manner as before, the pain or inflammation would be removed directly." Hence he endeavours to prove that the influence of the tractors is Galvanic, by an argument as abfurd as the pretended fact on which it is founded.

" On the application (fays he) of zinc and filver to the tongue, the fenfation of tafte is very flight to fome, while with others it is very ftrong:—when the experiment is applied to the fenfe of fight, fome are hardly fenfible of it, while others obferve a ftrong flafh." But, not to mention that neither ebony nor ivory can form part of the excitatory arc in *Galvanifm*, though we have

Perkinism.

have seen them both employed *successfully* as tractors by a Danish Perkinist, it is enough to observe, that the different effects of the Galvanic metals on different persons depend upon the difference of structure of the organs of sensation in the *patients*; whereas the different effects of the metallic tractors result, according to this account, from the difference of structure in the organs of sense of the various *operators!* Nay, what is still more extraordinary, if any thing can be more extraordinary than this, is, that the value of the tractors depends, not upon the *materials* of which they are made, or the *skill* of the manufacturer, but upon some inconceivable virtue conveyed by Mr Perkins to the *person* of him by whom they are *sold*. This we learn from a pamphlet published by Charles Cunningham Longworthy, surgeon in Bath; who informs us, that he sells tractors by *commission* from Mr Perkins the original manufacturer in London."

After this article was sent to the press, and thus much of it printed, we received, from a friend in London, a copy of Mr Perkins's last publication on the subject *; in which he endeavours to repel the objections urged by Dr Haygarth and others against the influence of the metallic tractors. Had we not been previously convinced of the falsity of Perkinism, the perusal of this pamphlet would have removed from our minds every doubt; for we will venture to say, that it is not in the power of Dr Haygarth, and the whole faculty united, to bring more complete proof than Mr Perkins has here brought, that what he calls his father's *discovery* has no claim to rank otherwise than with the discovery of Mesmer. See *Animal Magnetism*, Encycl.

* *The Eff- of Pe- Pa Meta &c. &c.*

He gives indeed 250 cases, which are attested to have been successfully treated by the tractors; but at least an equal number of cases were attested to have been successfully treated by Mesmer and his partisans; and six times that number of cures were said to have been miraculously performed at the tomb of the Abbé Paris (See Paris in this *Suppl.*) We would willingly allow, however, that these attestations ought to draw the attention of men of science to the subject, did not the author himself betray a want of confidence in the tractors, by his own arguments in their favour, and by his caution to the public against *counterfeits*. He seems indeed to consider their sanative influence as resulting entirely from his *patent*.

Dr Haygarth having said that he performed cures of the same kind with those of which Mr Perkins boasts, by the proper application of tractors made of *wood*; and having added, that "if any person would repeat these experiments, it should be done with due solemnity," in order to work upon the imagination; our author replies, by putting the following question: "Is there a single possessor of the *patent metallic* tractors in England who has frequently used them, and will say that this fraud is necessary to make *them* perform *cures?*" Instead of answering for the English possessors of these valuable instruments, we beg leave, in our turn, to ask, if there be a single expert chemist in Great Britain who can understand this question in any other sense, than as implying that the virtue of the tractors resides in the *patent?* This, however, appears still more palpable in the caution to the public.

"Among the various artifices (says Mr Perkins) which have been employed by certain interested persons, I have to mention the mean attempt to circulate *false tractors*, and from the failure of these to throw discredit upon the discovery. Three instances of this kind have occurred lately. Complaints having been made to me that my tractors would not cure the diseases for which they are recommended, I was led to make inquiry respecting the cases alluded to; and conceiving them fit subjects for the tractors, I called on the patients to apply them myself. In *both* instances (it was just now in *three* instances) I found they had been using *counterfeit* tractors. Had not this been discovered, the *merit* of the *patent* tractors must have suffered extremely!"

Perkinism, Perouse.

This is very extraordinary. The *character* or *fame* of any thing may indeed be injured by a counterfeit; but we believe this is the first instance of the *merit* or *demerit* of one inanimate substance being increased or diminished by another at a distance from it,--of the hardness of steel, for instance, being diminished by the softness of lead! But we beg Mr Perkins's pardon. The *merit* of his tractors consists in their putting money into his pocket; and *that* merit might certainly be injured by the use of *counterfeits*. Hence, with great propriety, he informs the public, that every *genuine set* is stamped with the words Perkins's patent tractors, accompanied with a receipt for the five guineas, numbered and signed in the handwriting of the patentee. From these facts we infer (and he must acknowledge the inference to be just), that the virtue of the tractors resides in the *patent*, restricting the making of them to *Benjamin Douglas Perkins*, and not to the *metal* of which they are made. This is indeed most obvious; for he cannot be such a stranger to the state of chemical science in this country, as to suppose that his tractors may not be analysed into their component principles, and, of course, that others may not be made possessing all their virtues except such as result from the patent.

We shall conclude this article in the words of the reviewer already quoted: "To trace the relations and dependencies of projects similar to that of Dr Perkins, would now be a work of more labour than utility. The fund of public credulity is an inexhaustible resource for those who can resolve to levy contributions on it. In vain is the spirit of quackery exorcised in one form; it rises again immediately, 'with twenty ghastly murders on its head, to push us from our stools.' We, who have contemplated the progress of real knowledge during a long course of years, have seen many bubbles like this glitter for a moment, and then disappear for ever. People may talk of Mesmerism, or Perkinism, but we consider all such varieties as belonging to the old and extensive class of Charlatanism."

PEROUSE (John Francis Galoup de la), the celebrated, though unfortunate, French navigator, was born at Albi in 1741. Of the rank or condition of his father, M *Milet-Mureau* has given us no information in that meagre eulogy of Perouse which he has inserted in the introduction to his last voyage. It appears, however, that he intended to make his son a seaman, and sent him, at a very early period of life, to the marine school, where the young man became enthusiastically fond of his profession, and laudably ambitious to emulate the fame of the most celebrated navigators.

Being

Being appointed a midshipman on the 19th of November 1756, he behaved, we are told, with great bravery in that station, and was severely wounded in the engagement between the admirals Hawke and Conflans, on the 20th of November 1759. The Formidable, in which he served, was taken, after a vigorous resistance; and it is probable that Perouse reaped some advantage from his acquaintance with British officers.

On the 1st of October 1764 he was promoted to the rank of lieutenant; and despising a life of ease and idleness, he contrived to be employed in six different ships of war during the peace that subsisted between Great Britain and France. In 1767 he was promoted to the rank of what, in our navy, is called *master* and *commander*. In 1779 he commanded the *Amazone*, belonging to the squadron of Vice admiral Count d'Estaing; and when that officer engaged Admiral Byron, the post of La Perouse was to carry his Admiral's orders to the whole of the line. He afterwards took the sloop *Ariel*, and contributed to the capture of the *Experiment*—exploits which his eulogist seems to consider as instances of very uncommon heroism; but he soon after performed a greater.

Being, on the 4th of April 1780, appointed captain of the frigate *Astrea*, and being on a cruise with the *Hermione*, these two frigates attacked six English vessels of war, of from 28 to 14 guns each, and took two of them. The French certainly reaped more laurels about that period than they have been accustomed to do in naval wars with Great Britain; but as we have completely forgotten the particulars of this fight, we suspect that it was not altogether so very brilliant a business as M. Milet-Mureau is pleased to represent it.

In the year 1782, La Perouse was dispatched with the Sceptre of 74 guns, and two frigates of 36 guns each, having some troops and field pieces on board, to destroy the English settlements in Hudson's Bay. This task was easily accomplished; for when he had surmounted the difficulties of navigation in a frozen sea, he found nothing on shore to oppose the smallest force. Having destroyed the settlements, he learned that some of the English had fled at his approach into the woods; and his eulogist considers it (such are the dispositions of French republicans) as a most wonderful instance of humanity, that he left to these unfortunate men provisions to preserve them from perishing by hunger, and arms to protect them from the fury of the savages! Perouse, we dare answer for him, was conscious of nothing heroic or extraordinary in this act of beneficence, which he certainly could not have omitted, without incurring both infamy and guilt.

In the year 1785, he was appointed to the command of a voyage round the world; which was unfortunately destined to be his last. Of this voyage, as far as it was accomplished, there is a full account in the hands of every French and English reader; and from that account it appears, that Perouse was admirably qualified to discharge such a trust. He seems to have been an experienced and skilful seaman; a man of considerable mathematical and physical science, uncorrupted by that philosophism which disgraced many of his attendants; and capable of the utmost perseverance in every laudable pursuit. To these qualities he united a proper combination of caution and courage, with a disposition truly benevolent to the various tribes of savages whom he visited. The disasters which occurred on the voyage were all, except the last, of which nothing is known, occasioned by the disobedience of his officers, or their neglecting to follow his advice.

The last dispatches of this great and good man were dated from Botany Bay, February the 7th 1788; and since that period, no account of him has been received which is intitled to the smallest confidence. *M. Milet-Mureau* has indeed given us, at some length, the childish conjectures of the Society of Natural History respecting his fate, which, in language equally childish, were delivered at the bar of the National Assembly; and he has added the ridiculous decree which that body of legislative sciolists passed in consequence of so extraordinary a speech. We will not disgrace our pages, or insult the memory of Perouse, by contributing to the circulation of nonsense, which, we are persuaded, would have made him blush for his country.

PERPENDICULAR, in gunnery, is a small instrument, used for finding the centre line of a piece in the operation of pointing it to a given object.

PERSIAN or PERSIC, in architecture, a name common to all statues of men, serving instead of columns to support entablatures.

PERWANNAH, in the language of Bengal, an order of government, or a letter from a person in authority.

PETERSBURGH (St), the capital of Russia, is a city, of which a pretty full historical detail has been given in the *Encyclopædia*. It is introduced here merely on account of its police, which, according to the anonymous author of the life of Catharine II. has a very simple and competent organization, and deserves to be adopted in other great capitals. Excepting the governor, whose office naturally extends to all objects of public welfare, the head police-master is the proper chief of the whole system of police. His office takes in the great compass of this department, but confined to the general objects of public security and order. He is not here, as in some large towns, the formidable copartner of family secrets, and the invisible witness of the actions of the private man. Under the head police-master is the police office, where sit a police master, two presidents, the one for criminal, the other for civil cases, and two consulters, chosen from the burgher class. To this is committed the care to maintain decorum, good order, and morals: also it is its business to see to the observance of the laws, that the orders issued by government, and the decisions of the courts of justice, are put in force. The attainment of these purposes is effected by the following mechanism:

The residence is divided into ten departments. Each of these has a president, appointed to watch over the laws, the security, and the order of his district. The duties and rights of this office are not less extensive than important. A president must have exact knowledge of the inhabitants of his department, over which a sort of parental authority is committed to him; he is the *censor morum* of his department; his house must not be bolted or barred by night or day, but must be a place of refuge, continually open to all that are in danger or distress; he himself may not quit the town for the space of two hours, without committing the discharge of his office to some other person. The police commando (constables), and the watchmen of his department, are

Peterſburgh.

under his orders; and he is attended on all affairs of his office by two ſerjeants. Complaints againſt unjuſt behaviour in the preſident may be brought to the police office.

Each department is again divided into three, four, or five ſubdiviſions, called quarters, of which, in the whole reſidence, are 42. Each of theſe has a quarter-inſpector, in ſubordination to whom is a quarter-lieutenant. The duty of theſe police-officers is in harmony with that of the preſident, only that their activity is confined to a ſmaller circle. They ſettle low affairs and ſlight altercations on the ſpot, and keep a watchful eye on all that paſſes.

The number of the nightly watch in the city amounts to 500. They have their ſtations aſſigned them in watch houſes at the corners of ſtreets; and, beſides their proper deſtination, are to aſſiſt in the taking up of offenders, and in any ſervice, by day or night, as their commanders ſhall require. Beſides theſe, for the execution of the police orders, and to act as patroles, there is alſo a commando of 120 men, who, in caſes of emergency, are ſupported by a company of koſaks, or a regiment of huſſars.

This machine, conſiſting of ſo many ſubordinate parts, preſerves in its orderly courſe that ſecurity and peace which excite the admiration of all foreigners. The activity of every individual member is unobſerved in the operation of the whole; and by ſuch a diſtribution alone is the attainment of ſo complicated an aim practicable.—All the quarter inſpectors of a department repair every morning, at ſeven o'clock, to their inſpector's houſe, to lay before him the report of all that has happened in their quarters during the laſt 24 hours; and at eight o'clock, all the inſpectors bring together theſe ſeveral reports into the police office, whereupon they ſit and immediately take into examination the caſes of perſons taken into cuſtody during the night. On urgent occaſions, the police office aſſembles at all hours.

This organization, and the extraordinary vigilance of the police, which is found competent to the buſineſs of a numerous and reſtleſs people, render all ſecret inquiſitions unneceſſary. The police has knowledge of all perſons in the reſidence; travellers who come and go are ſubject to certain formalities, which render it extremely difficult to conceal their place of abode, or their departure from the city. To this end, every houſeholder and innkeeper is obliged to declare to the police, who lodges with him, or what ſtrangers have put up at his houſe If a ſtranger or lodger ſtays out all night, the landlord muſt inform the police of it at lateſt on the third day of his abſence from his houſe. The cautionary rules, in regard to travellers quitting the town, are ſtill more ſtrict. Theſe muſt publiſh in the newſpapers their name, their quality, and their place of abode, three ſeveral times, and produce the newſpapers containing the advertiſement, as a credential in the government from which they then receive their paſſport; without which, it is next to impoſſible to get out of the empire. This regulation not only ſecures the creditor of the perſon about to depart, but alſo enables the police to keep a cloſer inſpection over all ſuſpected inhabitants.

If individuals may be ſuſpected by the government, becauſe their means of ſupport, the company they keep, and their whole courſe of action, are cloſely wrapped up in myſtery; ſo likewiſe may whole ſocieties be leſs indifferent to it, if they carefully conceal the object of their connection, or their very exiſtence, from the eye of the public. The police watches here, with laudable attention, over ſecret ſocieties of all kinds; and frequently as the fanatical ſpirit of religious or political ſectaries, or the enthuſiaſm of pretended myſtagogues, have attempted to neſtle here, they have never been able to proceed, or only for a very ſhort time. Animal magnetiſm, Martiniſm, Roſycrutianiſm, and by whatever other name the conceits of diſtempered imaginations may be called, have always been attended with the ſame bad ſucceſs on this ſtage.

From this ſketch it will be readily imagined, that the number of impoſtors and diſturbers of the public peace can be but ſmall. Quarrels and affrays in the ſtreet or in the cabaks but ſeldom happen. The perſon attacked calls the neareſt watchman; and in a moment both the aggreſſor and the aggrieved are taken into cuſtody, and led to the next ſieja (police-watch houſe), where the cauſe of their quarrel is inquired into, and the aggreſſor is puniſhed. For matters of ſome deſcriptions, there is a peculiar tribunal, under the denomination of the oral court, which, on account of its ſingularity, deſerves to be briefly noticed.

In each quarter of the town are one or more judges of the oral court, who are choſen from the claſs of burghers, and with whom are aſſociated a few jurats. This court ſits daily in the forenoon, and proceeds orally in all the differences that come before it. It, however, keeps a day-book, in which are entered all the cauſes and deciſions of the court, and which muſt be every week laid before the magiſtrate. When a charge is brought, the court declares it orally to the preſident of the quarter: whereupon the accuſed muſt not delay his appearance before the police longer than one day after he has received the ſummons. Every cauſe muſt be determined in one day, or, if the examinations require more time in collecting, in three days. The oral court communicates the deciſion to the preſident of the quarter by means of his day-book, in order to its ratification. If either party is not ſatisfied with the ſentence, he may appeal to the court as appointed in the regulations.

This is a very favourable account of the police of St Peterſburgh; but it is differently repreſented in *Beaujolin's Travels of two Frenchmen through Ruſſia*, in 1790—1792. According to him, the police of the capital of that empire is far from being on the moſt reſpectable footing. There happen, indeed, but few accidents in the night; yet ſometimes murders are committed, and eſpecially thefts; for which, according to our author, it is exceedingly rare to obtain juſtice. When a perſon has been aſſaſſinated in ſome place of bad repute, the police officer is engaged to ſecrecy by means of a few rubles; ſo that the affair is ſoon huſhed up, unleſs the deceaſed belonged to ſome powerful family, whoſe intereſt makes it neceſſary that inquiries ſhould be inſtituted. When two perſons quarrel, either in the ſtreet or in a public houſe, he who *pays* the inquirer is always in the right: the inferior police-officers are never proof againſt money; and the *poor* individual, whether he be in the right or wrong, is almoſt ſure of a beating.

PETIVER (James), a famous Engliſh botaniſt, was

Petiver, Phasianus.

contemporary with Plukenet; but the exact time of his birth is not known, nor is much intelligence concerning him at present to be obtained. His profession was that of an apothecary, to which he was apprenticed under Mr Feltham, then apothecary to St Bartholomew's hospital *. When he entered into business for himself, he settled in Aldersgate street, and there continued for the remainder of his life. He obtained considerable business, and after a time became apothecary to the charter house. After the Tradescants, he appears to have been the only person, except Mr Courten and Sir Hans Sloane, who made any considerable collection in natural history, previous to those of the present day. He engaged the captains and surgeons of ships to bring him home specimens, and enabled them to select proper objects, by printed directions which he distributed among them. By these means his collection became so valuable, that some time before his death, Sir Hans Sloane offered him L. 4000 for it. After his death, it was purchased by the some collector. His museum extended his fame both at home and abroad. He was elected into the Royal Society; and becoming acquainted with Ray, assisted him in arranging the second volume of his History of Plants. He died April 20. 1718: and much honour was shewn to him at his funeral, by the attendance of Sir Hans Sloane, and other eminent men, as pall bearers, &c. By future botanists, his name was given to a plant. See PETIVERIA, *Encycl.*

* Pulteney's *Sketches of Botany in England.*

He gave the world several publications on various subjects of natural history: 1. *Musei Petiveriani Centuria decem*, 1692—1703, 8vo. 2. *Gazophylacii Naturæ et Artis, Decades decem*, folio, 1702, with 100 plates. 3. A Catalogue of Mr Ray's English Herbal, illustrated with figures, folio, 1713, and continued in 1715. 4. Many small publications, which may be found enumerated in Dr Pultney's book. 5. Many papers in the Philosophical Transactions, and a material article in the third volume of Ray's work, entitled, *Plantæ Rariores Chinenses Madraspatanæ, et Africanæ, a Jacobo Petivero ad opus Consummandum Collatæ*, &c. Many of his smaller tracts having become very scarce, his works were collected and published, exclusive of his papers in the Transactions, in 2 vols folio, and one 8vo, in the year 1764.

PHASIANUS (See *Encycl.*). A species of this genus of birds, formerly not described, was sent from Batavia to England by Lord Macartney, or some of his attendants, when they were on their voyage to China. The species to which it seemed to be most nearly allied, in point of general habit or appearance, was the *phasianus curvirostris*, or Impeyan pheasant; an East Indian bird, described and figured both in Mr Latham's Ornithology, and in the Museum Leverianum. From that bird, however, it differs very considerably. The tail of the latter being in a mutilated state, it was scarce possible to determine, with absolute precision, whether it should be referred to that subdivision of pheasants, which contains those with long or cuneiform tails, or those with rounded ones, as in the Impeyan pheasant. The general colour of this most elegant bird was black, with a gloss of blue, or what, in the language of natural history, may be termed chalybean black, or black accompanied by a steel blue lustre. The lower part of the back was of a peculiarly rich colour, which, according to the different directions of the light, appeared either of a deep ferruginous or of the brightest fiery orange-red. This beautiful colour passed in the manner of a broad zone round the whole body, but on the abdomen was of a much more obscure appearance than on the back, as well as somewhat broken or irregular, especially on the sides. The throat was furnished with a large, and somewhat angular, pair of wattles, uniting with the bare spaces on the cheeks. The feathers on the top of the head, which was of a lengthened form, ran a little backward, so as to give the appearance of an indistinct occipital crest. The beak was remarkable for a more lengthened and curved aspect than in any other bird of this genus, except the Impeyan pheasant. The feathers on the neck, back, and breast, were rounded, and of the same shell-like or scaly habit as those of the turkey. The legs very stout, and were armed with a pair of extremely strong, large, and sharp spurs. Both legs and beak were of a pale colour. Whether this bird be really new or not to the ornithologists of Europe, it may at least be affirmed with safety, that it had never been properly described; nor can the character of any species, hitherto introduced into the books of any systematic naturalist, be considered as a just or competent specific character of the present bird. It may be called the *fire backed pheasant*; and its essential character may be delineated in the following terms: Black pheasant with a steel-blue gloss; the sides of the body rufous; the lower part of the back fiery ferruginous; the tail rounded; the two middle feathers pale yellow brown.—*Sir George Staunton's Account of an Embassy to China, &c.*

Phasianus, Philosophist, Ph

PHILOSOPHIST, a lover of sophistry or false reasoning, in contradistinction to *philosopher*, who is a lover of sound reasoning, true science, and practical wisdom.

CRITICAL PHILOSOPHY.

1 Origin of the science.

CRITICAL PHILOSOPHY, is the appellation given to a system of science, of which the founder is *Immanuel Kant*, regius professor of logic and metaphysics in the university of Koenigsberg. Of this system, which is very generally admired in Germany, we promised, in our Prospectus, to gratify our speculative readers with a short view; and that promise we are enabled to fulfil, by the kind communication of an illustrious foreigner, who, after acting a conspicuous part on the theatre of the world, and striving in vain to stem the torrent of democratic innovation, is now living an exile from his wretched country, and cultivating the sciences and the arts of peace.

2 Obscurity of its language.

"To explain (says he) the philosophy of Kant in all its details, would require a long and a painful study, without producing any real advantage to the reader. The language of the author is equally obscure, and his reasonings equally subtle, with those of the commentators of Aristotle in the 15th century."

The truth of this assertion will be denied by none, who

who have endeavoured to make themselves masters of the works of *Willich* and *Nitsch* on the critical philosophy; and the source of this obscurity seems to be sufficiently obvious. Besides employing a vast number of words of his own invention, derived from the Greek language, Kant uses expressions, which have long been familiar to metaphysicians, in a sense different from that in which they are generally received; and hence a large portion of time is requisite to enable the most sagacious mind to ascertain with precision the import of his phraseology.

The difficulty of comprehending this philosophy has contributed, we believe, more than any thing else, to bring it into vogue, and to raise the fame of its author. Men are ashamed, after so laborious and fatiguing a study, to acknowledge that all their labour has been thrown away; and vanity prompts almost every man to raise the importance of that branch of science which is understood but by a few, and in which he is conscious that his own attainments have been great. "We acknowledge, however, that in the system of Kant there is displayed much genius, combination, and systematic arrangement; but this only affords one of the many reasons which it presents, for our regretting that the author has not directed his mind to more useful researches, and that he has wasted the strength of his genius in rendering uncertain the most comfortable truths, and in giving the appearance of novelty to opinions for the most part taught long before his day.

The following analysis, we believe, will sufficiently enable any one, at all conversant with metaphysical science, to form a judgment of this celebrated system; and our correspondent, on whose word the reader may rely, assures us, that, in detailing the principles of Kant, he has taken special care to exhibit them with the utmost possible exactness, having several times preferred the obscurity of the author's reasonings and language, to the danger of a false, though more perspicuous, interpretation.

Division of human knowledge.

'Kant divides all our knowledge into that which is *a priori*, and that which is *a posteriori*. Knowledge *a priori* is conferred upon us by our nature. Knowledge *a posteriori* is derived from our sensations, or from experience; and is by our author denominated *empyric*. One would at first be induced, by this account of the origin of human knowledge, to believe that Kant intended to revive the system of *innate ideas*; but we very quickly discover that such is not his system. He considers all our knowledge as acquired. He maintains, that experience is the *occasional cause* or *productrice* of all our knowledge; and that without it we could not have a single idea. Our ideas *a priori*, he says, are produced *with* experience, and could not be produced *without* it; but they are not produced *by* it, or do not proceed *from* it. They exist in the mind; they are the *forms* of the mind. They are distinguished from other ideas by two marks, which are easily discerned; *i. e.* they appear *universal* and *necessary*; or, in other words, they admit of no exception, and their *converse* is impossible. Ideas which we derive from experience have no such characters. We can suppose, that what we have seen, or felt, or heard once, we may see, or feel, or hear again; but we do not perceive any impossibility in its being otherwise. For instance, a house is on fire in my view: I am certain of this fact; but it affords me no *general* or *necessary* knowledge. It is altogether *a posteriori*; the materials are furnished by the individual impression which I have received; and that impression might have been very different.

"But if I take twice two small balls, and learn to call twice two *four*, I shall be immediately convinced, that any two bodies whatever, when added to any two other bodies, will constantly make the sum of bodies *four*. Experience has indeed afforded me the *opportunity* of acquiring this knowledge; but it has not given it to me; for how could experience prove to me that this truth shall never vary? Experience must always be *limited*; and therefore cannot teach us that which is *necessary* and *universal*. It is not experience which discovers to us, that we shall always have the surface of the whole pyramid by multiplying its base by the third part of its height; or that two parallel lines, extended *in infinitum*, shall never meet.

"All the truths of pure mathematics are, in the language of Kant, *a priori*. Thus, that a straight line is the shortest of all possible lines between two fixed points; that the three angles of a triangle are always equal to two right angles; that we have the same sum, whether we add 5 to 7 or 7 to 5; and that we have the same remainder when we subtract 5 from 10 as when we subtract 10 from 15—are so many propositions, which are true *a priori*.

4 Pure knowledge *a priori*.

"Pure *knowledge a priori*, is that which is absolutely without any mixture of experience. *Two and two men make four men*, is a truth, of which the knowledge is *a priori*; but it is not PURE knowledge, because the truth is particular. The ideas of *substance*, and of *cause* and *effect*, are *a priori*; and when they are separated from the objects to which they refer (we suppose from this or that *particular* object), they form, in the language of Kant, *void ideas* (A). It is our knowledge *a priori*, *i. e.* that knowledge which precedes experience as to its origin, which renders experience possible (B). Our faculty of knowledge has an effect on our ideas of sensation analogous to that of a vessel, which gives its own form to the liquor with which it is filled. Thus, in all our knowledge *a posteriori*, there is something *a priori* derived from our faculty of knowledge. All the operations of our minds; all the impressions which our external and internal senses receive and retain, are brought into effect by the *conditions*, the *forms*, which exist in us by the pure ideas *a priori*, which alone render all our other knowledge certain.

5 Time and space.

"*Time* and *space* are the two essential forms of the mind:

(A) In the language of Locke *abstract ideas*.

(B) In our correspondent's manuscript, this sentence runs thus: "It is our knowledge *a priori*, or that knowledge which *entirely precedes experience* as to its origin, which experience renders possible;" but here must be some mistake, either by the translator or by the amanuensis. Kant's philosophy is abundantly obscure and paradoxical; but it surely never entered into his head to represent the effect as prior in its origin to the very cause which alone renders it possible. The context, too, seems to us to agree better with the meaning of the sentence as we have printed it in the text.

mind: the former for impressions received by the internal sense; the second for those received by our external senses. Time is necessary in all the *immediate* (perhaps *intuitive*) perceptions of objects; and space in all *external* perceptions.

6 Extension. "*Extension* is nothing real but as the form of our sensations. If extension were known to us only by experience, it would then be possible to conceive that there might be sensible objects without space.

7 Impenetrability, &c. "It is by means of the form *space* that we are enabled, *a priori*, to attribute to external objects *impenetrability*, *divisibility*, *mobility*, &c.; and it is by means of the form *time* that we attribute to any thing *duration*, *succession*, *simultaneity*, *permanence*, &c.

Origin of arithmetic and geometry. "*Arithmetic* is derived from the form of our internal sense, and *geometry* from that of our external.

9 Unifying power of the mind. "Our understanding collects the ideas received by the impressions made on our organs of sense, confers on these ideas *unity* by a particular *force* (we suppose energy) *a priori*; and thereby forms the representation of each object. Thus, a man is successively struck with the impressions of all the parts which form a particular garden. His understanding unites these impressions, or the ideas resulting from them; and in the unity produced by that unifying act, it acquires the idea of the garden. If the objects which produce the impressions afford also the *matter* of the ideas (c), then the ideas are *empyric*; but if the objects only unfold the *forms of the thought*, the ideas are *a priori*. The act of the understanding which unites the perceptions of the various parts of an object into the perception of one whole, is the same with that which unites the attribute with its subject.

10 Analytic judgments. "Judgments are divided into two species; *analytic* and *synthetic*. An analytic judgment is that in which the attribute is the mere developement of the subject, and is found by the simple analysis of the perception; as *bodies are extended*; *a triangle has three sides*.

11 Synthetic judgments. "A synthetical judgment is that where the attribute is connected with the subject by a cause (or basis) taken from the faculty of knowledge, which renders this connection necessary: as, *a body is heavy*; *wood is combustible*; *the three angles of a triangle are equal to two right angles*. There are syntheses *a priori* and *a posteriori*; and the former being formed by experience, we have the sure means of avoiding deception.

It is a problem, however, of the utmost importance, to discover how synthetic judgments *a priori* are possible. How comes it, for example, that we can affirm that all the radii of a circle are equal, and that two parallel lines will never meet? It is by studying the *forms* of our mind that we discover the possibility of making these affirmations. In all objects there are things which must necessarily be THOUGHT (be supplied by thought); as, for example, that there is *a substance*, an *accident*, a *cause*, and certain *effects*.

12 Forms of the understanding. "The *forms* of the understanding are, *quantity*, *quality*, *relation*, *modality*.

"Quantity, Kant distinguishes into *general*, *particular*, and *individual*; quality, into *affirmation*, *negation*, *infinite*; relation, into *categoric*, *hypothetic*, and *disjunctive*; and modality, into *problematic*, *certain*, and *necessary*. He adds also to these properties of the four principal forms of the understanding, a table of *categories*, or fundamental ideas *a priori*.

"Quantity, gives *unity*, *plurality*, *totality*. Quality, gives *reality*, *negation*, *limitation*. Relation, gives *inherence*, *substance*, *cause*, *dependence*, *community*, *reciprocity*. Modality, gives *possibility*, *impossibility*, *existence*, *nothing*, *necessity*, *accident*. These categories can only be applied to experience. When, in the consideration of an object, we abstract all that regards sensation, there remain only the pure ideas of the understanding, or the *categories*, by which a *thing* is conceived as a *thing*. 13 Categories.

"Pure reason is the faculty of tracing our knowledge *a priori*, to subject it to principles, to trace it from its necessary conditions, till it be entirely without condition, and in complete unity. This pure reason has certain fundamental rules, after which the necessary connection of our ideas is taken for the determination of the objects in themselves;—an illusion which we cannot avoid, even when we are acquainted with it. We can conclude from what we know to what we do not know; and we give an *objective* reality to these conclusions from *an appearance* which leads us on.

"The writings of Kant are multifarious; but it is in his work entitled the *Critique of Pure Reason* that he has chiefly expounded his system. This work is a treatise on a pretended science, of which Kant's scholars consider him as the founder, and which has for its objects the *natural forces*, the *limits of our reason*, as the source of our pure knowledge *a priori*, the *principles of all truth*. Kant does not propose to give even an exposition of these branches of knowledge, but merely to examine their origin; not to extend them, but to prevent the bad use of them, and to guard us against error. He denominates this science *transcendental criticism*; because he calls all knowledge, of which the object is not furnished by the senses, and which concerns the kind and origin of our ideas, *transcendental knowledge*. The Criticism of Pure Reason, which gives only the fundamental ideas and maxims *a priori*, without explaining the ideas which are derived from them, can lead (says Kant) to a complete system of pure knowledge, which ought to be denominated *transcendental philosophy*, of which it (the *Criticism*, &c.) presents the *architectonic* plan, *i. e.* the plan regular and well disposed. 14 Critique of pure reason.

"The work entitled *The Critique of Pure Reason*, is divided into several parts or sections, under the ridiculous titles of *Æsthetic transcendental*; of *transcendental logic*; of *the pure ideas of the understanding*; of *the transcendental judgment*; of *the paralogism of pure reason*; of *the ideal transcendental*; of *the criticism of speculative theologies*; of *the discipline of pure reason*, &c.

"But to proceed with our abstract of the system. We know objects only by the manner in which they affect us; and as the impressions which they make upon us are only certain *apparitions* or *phenomena*, it is impossible for us to know what an *object is in itself*. 15 We cannot know objects as they are in themselves.
consequence of this assertion, some have supposed that Kant is an *idealist* like Berkeley and so many others, who have thought that sensations are only *appearances*, and

(c) This is wonderful jargon; but the reader will reflect that it is not o

and that there is no truth but in our reason; but such is not the opinion of Kant (D). According to him, our understanding, when it considers the apparitions or phenomena, acknowledges the *existence* of the objects in themselves, inasmuch as they serve for the bases of those apparitions; though we know nothing of their *reality*, and though we can have no certitude but in experience.

"When we apply the *forms* of our understanding, such as *unity*, *totality*, *substance*, *causality*, *existence*, to certain ideas which have no object in *space* and *time*, we make a fallacious and arbitrary application. All these forms can bear only on sensible objects, and not on the *world of things in itself*, of which we can THINK, but which we CAN NEVER KNOW. Beyond things sensible we can only have *opinions* or a *belief* of our reason.

16 Objective and subjective truths. "The motives to consider a proposition as true, are either *objective*, *i. e.* taken from an *external* object, so that each man shall be obliged to acknowledge them; and then there is a truth *evident* and susceptible of *demonstration*, and it may be said that we are *convinced*; or the motives are *subjective*, *i. e.* they exist only in the mind of him who judges, and he is *persuaded*.

"TRUTH, then, consists in the agreement of our *notions* with the *objects*, in such a manner as that all men are obliged to form the same judgment; BELIEF consists in holding a thing for true in a *subjective manner*, in consequence of a persuasion which is entirely personal, and has not its basis in an object submitted to experience.

17 Belief. "There is a *belief of doctrine*, of which Kant gives, as an example, this assertion—'there are inhabitants in the planets.' We must acknowledge (he adds) that the ordinary mode of teaching the existence of God belongs to *the belief of doctrine*, and that it is the same with *the immortality of the soul*. *The belief of doctrine* (he continues) has in itself something *staggering*; but it is not the same with *moral belief*. In moral belief there is something *necessary*; it is (says he), that I should obey the law of morality in all its parts. The end is strongly established; and I can perceive only one condition, by means of which this end may be in accord with all the other ends, *i. e.* that *there is a God*. I am certain that no man knows any other condition which can conduct to the same unity of end under the moral law; which law is a law of my reason. I will consequently believe certainly the *existence of God*, and a *future life*; because this persuasion renders immoveable my moral

18 Proof of the existence of God, &c. principles—principles which I cannot reject without rendering myself contemptible in my own eyes. I wish for happiness, but I do not wish for it without morality; and as it depends on *nature*, I cannot wish it with this condition, except by believing that nature depends on a Being who causes this connection between morality and happiness. This supposition is founded on the *want* (or *necessity*) of my reason, and not on my duty.

"We have, however, no *certainty* (says Kant) in our knowledge of God, because certainty cannot exist except when it is founded on an object of experience. The philosopher acknowledges, that *pure reason* is too weak to prove the existence of a being beyond the reach of our senses. The necessity of believing in God is therefore only *subjective*, although necessary and general for all those beings who conform to their duty. This is not *knowledge*, but only a *belief* of reason, which supplies the place of a knowledge which is impossible (E).

"The proofs of natural theology (says our philosopher) taken from the order and beauty of the universe, &c. are proofs only in *appearance*. They resolve themselves into a bias of our reason to *suppose* an Infinite Intelligence as the author of all that is possible; but from this bias it does not follow that there really is such an Author. To say, that whatever exists must have a cause, is indeed a maxim *a priori*; but it is a maxim applicable only to experience, for one knows not how to subject to the laws of our perceptions that which is absolutely independent of them. It is as if we were to say, that whatever exists in experience must have an experience; but the world, taken as a whole, is without experience as well as its cause. It is much better to draw the proof of the existence of God from morality, than to weaken it by such reasoning. This proof is relative. It is impossible to *know* that God exists; but we can comprehend how it is possible to act morally on the *supposition* of the existence (although incomprehensible) of an intelligent Creator—an existence which PRACTICAL REASON forces THEORETICAL *reason* to adopt. This proof not only *persuades*, but even acts on the CONVICTION, in proportion as the motives of our actions are conformable to the law of morality.

"Religion ought to be the *means* of virtue and not its object. Man has not in himself the idea of religion as he has that of virtue. The latter has its principle in the mind; it exists in itself, and not as the means of happiness; and it may be taught without the idea of a God, for the pure law of morality is *a priori*.

"He who does good by inclination does not act *morally*. The converse of the principle of morality is to make personal happiness the basis (F) of the will. 19 Morality. There are compassionate minds which feel an internal pleasure in communicating joy around them, and who thus enjoy the satisfaction of others; but their actions, however just, however good, have no moral merit, and may be compared to other inclinations; to that of honour

(D) We must request the reader to observe that this is the language of our correspondent. We have shewn elsewhere, that Berkeley did not deny the reality of sensations; and we hope to shew by and bye, that Kant is as much an *idealist* as he was, if this be a fair view of the Critical Philosophy.

(E) We have here again taken the liberty to alter the language of our correspondent. He makes Kant say, "It is not this knowledge, but a *belief* of reason, &c.;" but this is surely not the author's meaning. From the context, it is apparent that Kant means to say, that we have not, and cannot have, what can be properly called a *knowledge* of the existence of God, but only such a belief of his existence as supplies the place of this impossible knowledge.

(F) This is a very absurd phrase. We suppose Kant's meaning to be, that the principles of him whose actions and volitions are influenced by the prospect of personal happiness, are the reverse of the pure principles of morality.

honour (for example), which, whilst it meets with that which is just and useful, is worthy of praise and encouragement, but not of any high degree of esteem. According to Kant, we ought not even to *do good*, either for the pleasure we feel in doing it, or in order to be happy, or to render others happy; for any one of these additions (perhaps motives) would be *empyric*, and injure the purity of our morals. A reasonable being ought to desire to be exempted from all *inclinations*, and never to do his duty but for his duty's sake.

"We ought to act after the maxims derived *a priori* from the faculty of knowledge, which carry with them the idea of necessity, and are independent of all experience; after the maxims which, it is to be wished, could be erected into GENERAL LAWS for all beings endowed with reason."

20 Futility of this system.

If this be a correct view of the object and the results of the critical philosophy, and the character of him from whom we received it permits us not to doubt of its being nearly correct, we confess ourselves unable to discover any motive which should induce our countrymen, in their researches after truth, to prefer the dark lantern of Kant to the luminous torch of Bacon. The metaphysical reader will perceive, that, in this abstract, there is little which is new except the phraseology; and that what is new is either unintelligible or untenable.

21 Of which the fundamental principles are not new.

The distinction between knowledge *a priori* and knowledge *a posteriori*, is as old as speculation itself; and the mode in which Kant illustrates that distinction differs not from the illustrations of Aristotle on the same subject. The Stagyrite talked of *general forms*, or *formal causes*, in the mind, as well as the professor at Koenigsberg; and he or his disciples (for we quote from memory) compared them to the form of the statue in the rough block of marble. As that form is brought into the view of the spectator by the chissel of the statuary, so, said the peripatetics, are the general *forms* in the mind brought into the view of consciousness by sensation and experience.

Such was the doctrine of Aristotle and his disciples, and such seems to be the doctrine of Kant and his followers; but it is either a false doctrine, or, if it be true, a doctrine foolishly expressed. A block of marble is capable of being cut into any form that the statuary pleases; into the form of a man, a horse, an ox, an ass, a fish, or a serpent. Not one of these forms therefore can be inherent in it, or essential to it, in opposition to the rest; and a general form, including all the animals under it, is inconceivable and impossible. In like manner, the human mind is capable of having the ideas of a circle, a triangle, a square, of black, white, red, of four, sweet, bitter, of the odour of a rose, and the stench of a dunghill, of proportion, of musical sounds, and of a thousand other things. None of these ideas therefore can be essential to the mind in opposition to the rest; and every man, who is not an absolute stranger to the operations of his own intellect, knows well that he cannot think of a thousand things at once; or, to use the language of philosophers, have in his mind a general idea, comprehending under it a thousand things so discordant as colours and sounds, figures, and smells. If therefore Kant means to affirm, with Plato, that, previous to all experience, there are *actually* in the mind *general forms*, or *general ideas*, to which sensation, or experience, gives an opportunity of coming into view, he affirms what all men of reflection know to be false. If he means only to affirm, what seems to have been the meaning of Aristotle, that particular sensations give occasion to the intellect to form general ideas, he expresses himself indeed very strangely; but his doctrine on this subject differs not essentially from that of Locke and Reid, and many other eminent metaphysicians of modern times. Of abstraction and general ideas we have given our own opinion elsewhere (see METAPHYSICS, *Encycl.* Part I. Chap. iv.), and shall not here resume the subject.

22 Impropriety of term.

But when Kant says that his ideas *a priori* are *universal*, and *necessary*, and that their converse is *impossible*, he seems by the word *idea* to mean what more accurate writers express by the term *proposition*. There are indeed two kinds of propositions, of which both may be true, though the one kind expresses necessary and universal truths, and the other such truths as are contingent and particular. (See METAPHYSICS, *Encyc.* Part I. Chapter vii.) Propositions directly contrary to those which express particular and contingent truths may be easily conceived; whilst such as are contrary to necessary and universal truths are inconceivable and impossible; but we doubt whether *any idea*, in the proper sense of the word, has a *contrary* or, as he expresses it, a *converse*. *Nothing* is not contrary to *substance*, nor *black* contrary to *white*, nor *four* contrary to *sweet*, nor an *inch* contrary to an *ell*. Nothing is the negation of substance, and black the negation of white; four is different from sweet, and an inch is less than an ell; but between these different ideas we perceive no contradiction.

That Kant uses the term *idea* instead of *proposition*, or some word of similar import, is farther evident from his instances of *the house on fire*, and the manner in which we learn that any two bodies added to any two other bodies will constantly make the sum of *four bodies*. If it be his will to use the terms *a priori* and *a posteriori* in the sense in which other metaphysicians use the terms *necessary* and *contingent*, we can make no other objection to his distinction between these two propositions, but that it is expressed in very improper language. The house might certainly be *on fire* or *not* on fire; but twice two bodies *must* always make the sum of four bodies, and cannot possibly make any other sum.

The truth of this last proposition (he says) we cannot have learned from *experience*, because experience, being always limited, cannot possibly teach us what is *necessary* and *universal*. But this is egregious trifling. The experience employed here is not limited. A child unquestionably learns the import of the terms of numeration, as he learns the import of all other terms, by experience. By putting two little balls to two little balls, he learns to call the sum *four* balls. After two or three lessons of this kind with different bodies, his own reflection suggests to him, that the sum four has no dependance upon the shape or consistence of the bodies, but merely upon the *individuality* of each or their numerical difference; and individuality, or numerical difference, is as completely exemplified in two bodies of any kind as in two thousand.

23 With its consequences.

All the truths of pure mathematics (says Kant) are *a priori*. If he means that they are all *necessary*, and that the contrary of any one of them is *inconceivable*, he affirms nothing but what is true, and has been known

to

to all mathematicians these two thousand years. But, if he means that they are *innate* truths, not discovered by induction or ideal measurement, his meaning is demonstrably false. (See INDUCTION in this *Supplement.*) When he says, that it is not *experience* which discovers to us that we shall always have the surface of the pyramid, by multiplying its base by the third part of its height, he is right, if by experience he means the actual measurement of all possible pyramids; but surely he cannot mean that the truth of this measurement is innate in the mind, for it is in fact not a true but a false measurement (c). The base of a pyramid multiplied by the third part of its height gives, not the surface, but the solid contents of the pyramid; and he who understands the proposition on which this truth is immediately built, knows perfectly that Euclid proved it by a series of ideal measurements of those particulars in which all pyramids necessarily agree.

Kant seems often to confound sensation with experience; and if by experience he means *sensation*, when he says that *pure knowledge, a priori*, is that which is absolutely without any mixture of experience, he talks nonsense; for the most spiritual notions which men can form are derived from the operations of the mind on ideas of sensation. To the rest of the paragraph, respecting pure knowledge, we have hardly any objection to make. Locke, the great enemy of innate ideas, taught, before Kant was born, that our knowledge depends upon our organization and the faculties of our minds, as much as upon impressions made on the senses *ab extra*; that if our organs of sense were different from what they are, the taste of sugar might be bitter, and that of wormwood sweet; and that if we had not memory, and could not modify and arrange our ideas, all progress in knowledge would be impossible.

24 Groundless or false assertions. When our author talks of *time* and *space* as the two essential *forms* of the mind, we are not sure that we understand him. We have shewn elsewhere, that a conscious intelligence may be conceived which has no ideas either of space or of time (see METAPHYSICS, *Encycl.* n° 182, &c. and 209, &c.); and he who can affirm, that if extension were known to us only by *experience*, it would be possible to conceive sensible objects *without space*, has never attended to the force of what philosophers call *the association of ideas in the mind.* But what is here meant by sensible objects? Are they objects of touch, taste, or smell? Objects of touch cannot indeed be conceived without space; but what extent of space is suggested by the taste of sugar or the odour of a rose?

When Kant talks of the *form* space enabling us to attribute to external objects *impenetrability, mobility*, &c. he talks at random; and another man may, with as much propriety, and perhaps more truth, affirm the converse of his propositions, and say, that it is the impenetrability and mobility, &c. of external objects that enable us to form the idea called *space*, and the succession of some objects, compared with the permanence of others, that enables us to form the notion or mode called *time*.

On the two or three next paragraphs it is not worth while to detain the reader with many remarks. They abound with the same uncouth and obscure phraseology, and the same idle distinctions between ideas *a priori* and *a posteriori*. In n° 11. he affirms, that the three following propositions (*a body is heavy, wood is combustible*, and *the three angles of a triangle are equal to two right angles*) are all necessary judgments. 25 Bad logic. In one sense this affirmation is true, and in another it is false. We cannot, without speaking unintelligibly, give the name *body* to any substance which is not heavy; and we are not acquainted with any kind of *wood* which is not combustible; but surely it is not impossible to conceive a substance extended and divisible, and yet *not* heavy, to which the name *body* might be given without absurdity, or to conceive wood as incombustible as the mineral called *asbestos*. That the three angles, however, of a plane triangle can be either more or less than equal to two right angles, is obviously impossible, and must be perceived to be so by every intelligence from the Supreme down to the human. The three propositions, therefore, are not of the same kind, and should not have been classed under the same genus of *necessary* synthetic judgments.

In the critique of pure reason, Kant seems to teach that all demonstrative science must proceed from general principles to particular truths. Hence his *forms* of the understanding, and his *categories*, which, according to one of his pupils*, "lie in our understanding as pure notions *a priori*, or the foundation of all our knowledge. They are *necessary forms, radical* notions, of which all our knowledge *must* be compounded." But this is directly contrary to the progress of the human mind, which, as we have shewn in the article INDUCTION, already referred to, proceeds, in the acquisition of every kind of knowledge, from particular truths to general principles. This *transcendental philosophy* of Kant's, therefore, inverts the order of nature, and is as little calculated to promote the progress of science as the syllogistic system of Aristotle, which was likewise built on *categories* or *general forms*. His *transcendental esthetic*, which, according to Dr Willich, is the knowledge *a priori* of the *rules of sensation*, seems to be a contradictory expression, as it implies that a man may know the laws of sensation, without paying the smallest attention to the organs of sense.

* Dr Willich.

That we know objects only by the manner in which they affect us, and not as they are in themselves, is a truth admitted, we believe, by all philosophers, and certainly by Locke and Reid; but when Kant says that we know nothing of the *reality* of the objects which affect our senses, he seems to be singularly paradoxical. Berkeley himself, the most ingenious idealist perhaps that ever wrote, contends strenuously for the existence of a *cause* of our sensations distinct from our own minds; and because he thinks inert matter a cause inadequate

(c) This may look like cavilling, as the blunder may be either Kant's or our correspondent's, though neither of them can be supposed ignorant of the method of measuring the surface of a pyramid. We assure the reader, however, that we do not mean to cavil. We admit that both Kant and our correspondent know perfectly well how to measure the surface of a pyramid; but had that knowledge been *innate* in their minds, we cannot conceive the possibility of their falling into the blunder. The blunder, therefore, though the offspring of mere inadvertence, seems to be a complete confutation of the doctrine.

inadequate to this effect, he concludes, that every sensation of which we are conscious is a proof of the immediate agency of the Deity. But Kant, as we shall perceive by and bye, makes the existence of God and of matter equally problematical. Indeed he says expressly, that beyond things sensible we can only have *opinions* or *belief;* but things sensible, as every one knows, are nothing more than the *qualities* of objects.

26 Tendency of the system towards atheism.

It should seem that the greater number of wonders which Kant has found in our primitive knowledge and in the faculties of our mind, the greater number of proofs ought he to have found of the existence and attributes of one First Cause: but so far is this from being the case, that we have seen him resting the evidence of this most important of all truths, either upon the *moral sense,* which our passions and appetites so easily alter, or upon the intuitive perception of *abstract moral rectitude;* a perception which thousands, as virtuous and as profound as he, have considered as impossible. Our philosopher's proof of a God is nothing more than his persuasion that happiness is connected with virtue by a Being upon whom nature depends; and he says expressly, that this proof carries conviction to the mind in proportion as the motives of a man's actions are conformable to the law of morality. This being the case, the reader cannot be much surprised, when he is informed that several of Kant's disciples on the continent have avowed themselves Atheists or Spinozists. We have elsewhere (see ILLUMINATI, n° 37.) mentioned one of those gentlemen who was lately dismissed from his professorial chair in the university of Jena, for making GOD nothing more than an *abstract idea,* derived from our relations with the moral world. His successor, a Kantist likewise, when it was told in his presence, that, during one of the massacres in Paris, David the Painter sat with his pencil in his hand, enjoying the sufferings of the unfortunate wretches, and trying to paint the expressions of their agonies, exclaimed—"What force of character! What sublimity of soul!" That this wretch must be an Atheist, likewise, follows of course from Kant's principles; for it is not conceivable that he perceives any connection between happiness and virtue.

That Kant is an atheist himself, we have not learned, though his doctrine leads thus naturally to atheism, and though in his work called TUGEND LEHRE, page 180, he makes the following strange observation upon oaths: "As it would be absurd to swear that God exists, it is still a question to be determined, whether an oath would be possible and obligatory if one were to make it thus—*I swear on the supposition that God exists.* It is extremely probable (says he), that all *sincere* oaths, taken with *reflection,* have been taken in no other sense!"

It is not our intention to plunge deeper into this mire of atheism, or to enter into a formal confutation of the detestable doctrines which have been dragged from its bottom. Enough has been said elsewhere to convince the *theoretical* reason of the sound minds of our countrymen of the existence of one omnipotent, infinitely wise, and perfectly good Being, the author and upholder of all things (See *Encycl.* METAPHYSICS, Part III. Chap. vi. and THEOLOGY, Part I. Sect. 1.). It may not, however, be altogether useless to point out to the reader how completely Kant confutes himself, even in the short abstract that we have given of his system.

27 Kant confutes himself.

Among his *categories,* or fundamental ideas, which are *necessarily* formed in the mind, he expressly reckons *cause* and *effect:* but in various articles of this work, it has been proved beyond the possibility of contradiction, that no *sensible* object is the *true metaphysical cause* of any one event in nature; and indeed Kant himself is at much pains to shew that his *categories* or ideas *a priori* are not ideas of sensation. There must therefore, upon his own principles, be causes which are *not* the objects of *sense* or *experience;* and by tracing these causes backward, if there be a succession of them, we must arrive at one self-existent cause, by a demonstration as complete as that by which Euclid proves the equality of the three angles of a plane triangle to two right angles. We have no other evidence for the truth of geometrical axioms than the laws of human thought, which compel us to perceive the impossibility of such propositions being false. According to our philosopher, we have the very same evidence for the reality of causes and effects which are not the objects of sense. The consequence is obvious.

His morality is extravagant.

Kant's *political* opinions are said to be tolerably moderate, though he betrays, what we must think, an absurd confidence in the *unlimited perfectibility* of the human mind. On his morality our valued correspondent has bestowed a much larger share of his approbation than we can allow it of ours. Kant seems to contend, that the actions of men should be directed to no end whatever; for he expressly condemns, as an end of action, the pursuit either of our own happiness or of the happiness of others, whether temporal or eternal; but actions performed for no purpose are surely indications of the very essence of folly. Such actions are indeed impossible to beings endowed with reason, passions, and appetites; for if there be that beauty in abstract virtue, for which Kant and the Stoics contend, it cannot be but that the virtuous man must feel an internal pleasure when he performs a virtuous action, or reflects upon his past conduct. He who makes his temporal interest the sole rule of his conduct, has indeed no pretensions to the character of a virtuous man; but as the morality of the gospel has always appeared to us sufficiently pure and disinterested, we think a man may, without deviating into vice, have respect unto "the recompence of future reward."

Phosphorus.

PHOSPHORUS (See CHEMISTRY-*Index, Supplement.*) has lately been employed as a medicine by Alphonsus Leroi, professor at the Medical School of Paris. Its effects, in a variety of cases, are thus described in the *Bulletin de la Societe Philomatique,* 1798.

1. Phosphorus administered internally in consumptive diseases appears to give a certain degree of activity to life, and to revive the patients, without raising their pulse in the same proportion. The author relates several instances that occurred to him in the course of his practice;

practice; one of which is as follows: Being called to attend a woman, at the point of death, who was quite worn out by a consumptive disorder, with which she had been afflicted for three years, in compliance with the earnest desire of her husband, who requested him to give her some medicine, he composed one of a portion of sirup diluted with water, in which a few sticks of phosphorus had been kept. Next day the woman found herself much better. She was revived for a few days; and did not die till about a fortnight after.

2. He himself, as he acknowledges, was so imprudent as to take two or three grains of solid phosphorus combined only with treacle, and experienced the most dreadful symptoms. At first he felt a burning heat in the whole region of the stomach. That organ seemed to be filled with gas which escaped by the mouth. Being dreadfully tormented, he tried to vomit, but in vain; and found relief only by drinking cold water from time to time. His uneasy sensations were at length al- but next morning he seemed to be endowed with an astonishing muscular force, and to be urged with an almost irresistible impulse to try its energy. The effect of this medicine at length ceased, adds the author, *à la suite d'un priapisme violent.*

3. In many cases the author employed, and still employs, phosphorus internally, with great benefit, to restore and revive young persons exhausted by excesses. He divides the phosphorus into very small particles, by shaking it in a glass filled with boiling water. He continues to shake the bottle, plunging it into cold water, and thus obtains a kind of precipitate of phosphorus, exceedingly fine, which he bruises slowly with a little oil and sugar, or afterwards employs as liquid electuary, by diluting the whole in the yolk of an egg. By means of this medicine he has effected astonishing cures, and restored the strength of his patients in a very short time.

4. In malignant fevers the use of phosphorus internally, to check the progress of gangrene, has succeeded beyond expectation. The author relates several instances. Pelletier told him, that having left, through negligence, some phosphorus in a copper bason, that metal was oxydated, and remained suspended in the water. Having thoughtlessly thrown out the water in a small court in which ducks were kept, these animals drink of it, and all died. *Mais le male* (says the author) *couvrit toutes ses femelles jusque au dernier instant de sa vie.* An observation which accords with the effect experienced by the author.

6. The author relates a fact which proves the astonishing divisibility of phosphorus. Having administered to a patient some pills, in the composition of which there was not more than a quarter of a grain of phosphorus, and having had occasion afterwards to open the body, he found all the internal parts luminous; and even the hands of the person who had performed the operation, though washed and well dried, retained a phosphoric splendor for a long time after.

7. The phosphoric acid, employed as lemonade, has been serviceable to the author in the cure of a great number of diseases.

8. Leroi assures us that he oxydated iron with phosphorus, and obtained, by the common means, a white oxyd, almost irreducible, which he thinks may be employed with advantage in the arts, and particularly in painting with oil, and in enamel, instead of the white oxyd of lead. This white oxyd of iron occasioned violent retchings to the author, who ventured to place a very small particle of it on his tongue. He does not hesitate, therefore, to consider this oxyd as a terrible poison. He was not able to reduce it but by fixed alkali and the glass of phosphorus.

9. The author asserts that, by means of phosphorus, he decomposed and separated from their bases the sulphuric, muriatic, and nitric acids; that by help of the phosphoric acid he transmuted earths; and that with calcareous earth he can make, at pleasure, considerable quantities of magnesia. He declares, that to his labours on phosphorus he is indebted for processes by which he effects the dissipation (*opère la frite*) of rubies, the fusion of emeralds, and the vitrification of mercury.

We agree with the editor of the respectable Miscellany *, from which we have immediately taken this article, that British practitioners will do well to use their wonted caution in the application of so powerful a remedy. Indeed we consider it as so very *hazardous* a remedy, that we had resolved to make no mention of it, till we found it transcribed into various journals, both foreign and domestic, and thence began to suspect that we might be accused of culpable negligence, were we to pass unnoticed what had attracted the attention of so many of our fellow-labourers in the field of science.

Phosphorus, in astronomy, is the morning star, or the [illegible] The Latins [illegible] and the G[illegible]

PHOTOMETER, [illegible] the intensity [illegible] the medium [illegible] Instruments for this purpose have been invented by Count Rumford, M. de Saussure, the eminent mathematician and philosopher Mr John Leslie, and others. We shall content ourselves with describing in this place the photometer of Count Rumford, and the instrument to which Saussure gives the name of *diaphanometer*. Mr Leslie's is indeed the simplest instrument of the kind of which we have anywhere met with a description; but it measures only the momentary intensities of light; and he who wishes to be informed of its construction, will find that information in the third volume of Nicholson's Philosophical Journal.

Count Rumford, when making the experiments which we have noticed in the article Lamp (*Suppl.*), was led, step by step, to the construction of a very accurate *photometer*, in which the shadows, instead of being thrown upon a paper spread out upon the wainscot, or side of the room (See page 64 of this volume), are projected upon the inside of the back part of a wooden box $7\frac{1}{2}$ inches wide, $10\frac{1}{2}$ inches long, and $3\frac{1}{2}$ inches deep, in the clear. The light is admitted into it through two horizontal tubes in the front, placed so as to form an angle of 60°; their axes meeting at the centre of the field of the instrument. In the middle of the front of the box, between these two tubes, is an opening thro' which is viewed the field of the photometer (See fig. 1.). Plate XLI. This field is formed of a piece of white paper, which is not fastened immediately upon the inside of the back of the box, but is pasted upon a small pane of very fine ground glass; and this glass, thus covered,

* Philosophical Magazine, vol

Photometer.

is let down into a groove, made to receive it, in the back of the box. The whole inside of the box, except the field of the instrument, is painted of a deep black dead colour. To the under part of the box is fitted a ball and socket, by which it is attached to a stand which supports it; and the top or lid of it is fitted with hinges, in order that the box may be laid quite open, as often as it is necessary to alter any part of the machinery it contains.

The Count had found it very inconvenient to compare two shadows projected by the same cylinder, as these were either necessarily too far from each other to be compared with certainty, or, when they were nearer, were in part hid from the eye by the cylinder. To remedy this inconvenience, he now makes use of two cylinders, which are placed perpendicularly in the bottom of the box just described, in a line parallel to the back part of it, distant from this back $2\frac{3}{10}$ inches, and from each other 3 inches, measuring from the centres of the cylinders; when the two lights made use of in the experiment are properly placed, these two cylinders project four shadows upon the white paper upon the inside of the back part of the box, or the *field* of the instrument; two of which shadows are in contact, precisely in the middle of that field, and it is these two alone that are to be attended to. To prevent the attention being [illegible] unnecessary objects, the [illegible] [illegible] be [illegible] of the [illegible] large [illegible] pro- [illegible] to [illegible] of [illegible] be [illegible] be [illegible] inches long [illegible] deep, viz. $3\frac{1}{2}$ inches; since the field [illegible] can be reduced to its proper size by a [illegible] pasteboard, interposed before the anterior [illegible] glass, and resting immediately upon it. [illegible] pasteboard, in the form of an oblong square, [illegible] wide, and two inches high, determines the dimensions, and forms the boundaries of the field. This screen should be large enough to cover the whole inside of the back of the box, and it may be fixed in its place by means of grooves in the sides of the box, into which it may be made to enter. The position of the opening above-mentioned is determined by the height of the cylinders; the top of it being $\frac{1}{10}$ of an inch higher than the tops of the cylinders; and as the height of it is only two inches, while the height of the cylinders is $2\frac{3}{10}$ inches, it is evident that the shadows of the lower parts of the cylinders do not enter the field. No inconvenience arises from that circumstance; on the contrary, several advantages are derived from that arrangement.

That the lights may be placed with facility and precision, a fine black line is drawn through the middle of the field, from the top to the bottom of it, and another (horizontal) line at right angles to it, at the height of the top of the cylinders. When the tops of the shadows touch this last mentioned line, the lights are at a proper height; and farther, when the two shadows are in contact with each other in the middle of the field, the lights are then in their proper directions.

We have said that the cylinders, by which the shadows are projected, are placed perpendicularly in the bottom of the box; but as the diameters of the shadows of these cylinders vary in some degree, in proportion as the lights are broader or narrower, and as they are brought nearer to or removed farther from the photometer, in order to be able in all cases to bring these shadows to be of the same diameter, which is very advantageous, in order to judge with greater facility and certainty when they are of the same density, the Count renders the cylinders moveable about their axes, and adds to each a vertical wing $\frac{45}{100}$ of an inch wide, $\frac{1}{20}$ of an inch thick, and of equal height with the cylinder itself, and firmly fixed to it from the top to the bottom. This wing commonly lies in the middle of the shadow of the cylinder, and as long as it remains in that situation it has no effect whatever; but when it is necessary that the diameter of one of the shadows be increased, the corresponding cylinder is moved about its axis, till the wing just described, emerging out of the shadow, and intercepting a portion of light, brings the shadow projected upon the field of the instrument to be of the width or diameter required. In this operation it is always necessary to turn the cylinder outwards, or in such a manner that the augmentation of the width of the shadow may take place on that side of it which is opposite to the shadow corresponding to the other light. The necessity for that precaution will appear evident to any one who has a just idea of the instrument in question, and of the manner of making use of it. They are turned likewise without opening the box, by taking hold of the ends of their axes, which project below its bottom.

As it is absolutely necessary that the cylinders should constantly remain precisely perpendicular to the bottom of the box, or parallel to each other, it will be best to construct them of brass; and, instead of fixing them immediately to the bottom of the box (which, being of wood, may warp), to fix them to a strong thick piece of well-hammered plate brass; which plate of brass may be afterwards fastened to the bottom of the box by means of one strong screw. In this manner two of the Count's best instruments are constructed; and, in order to secure the cylinders still more firmly in their vertical positions, they are furnished with broad flat rings, or projections, where they rest upon the brass plate; which rings are $\frac{1}{10}$ of an inch thick, and equal in diameter to the projection of the wing of the cylinder, to the bottom of which they afford a firm support. These cylinders are likewise forcibly pushed, or rather pulled, against the brass plate upon which they rest, by means of compressed spiral springs placed between the under side of that plate and the lower ends of the cylinders. Of whatever material the cylinders be constructed, and whatever be their forms or dimensions, it is absolutely necessary that they, as well as every other part of the photometer, except the field, should be well painted of a deep black dead colour.

In order to move the lights to and from the photometer with greater ease and precision, the observer should provide two long and narrow, but very strong and steady, tables; in the middle of each of which there

there is a straight groove, in which a sliding carriage, upon which the light is placed, is drawn along by means of a cord which is fastened to it before and behind, and which, passing over pulleys at each end of the table, goes round a cylinder; which cylinder is furnished with a winch, and is so placed, near the end of the table adjoining the photometer, that the observer can turn it about, without taking his eye from the field of the instrument.

Many advantages are derived from this arrangement: First, the observer can move the lights as he finds necessary, without the help of an assistant, and even without removing his eye from the shadows; secondly, each light is always precisely in the line of direction in which it ought to be, in order that the shadows may be in contact in the middle of the vertical plane of the photometer; and, thirdly, the sliding motion of the lights being perfectly soft and gentle, that motion produces little or no effect upon the lights themselves, either to increase or diminish their brilliancy.

These tables must be placed at an angle of 60 degrees from each other, and in such a situation, with respect to the photometer, that lines drawn through their middles, in the direction of their lengths, meet in a point exactly under the middle of the vertical plane or field of the photometer, and from that point the distances of the lights are measured; the sides of the tables being divided into English inches, and a vernier, shewing tenths of inches, being fixed to each of the sliding carriages upon which the lights are placed, and which are so contrived that they may be raised or lowered at pleasure; so that the lights may be always in a horizontal line with the tops of the cylinders of the photometer.

In order that the two long and narrow tables or platforms, just described, may remain immoveable in their proper positions, they are both firmly fixed to the stand which supports the photometer; and, in order that the motion of the carriages which carry the lights may be as soft and gentle as possible, they are made to slide upon parallel brass wires, 9 inches asunder, about $\frac{1}{10}$ of an inch in diameter, and well polished, which are stretched out upon the tables from one end to the other.

The structure of the apparatus will be clearly understood by a bare inspection of Plate XLI. where fig. 1. is a plan of the inside of the box, and the adjoining parts of the photometer. Fig. 2. Plan of the two tables belonging to the photometer. Fig. 3. The box of the photometer on its stand. Fig. 4. Elevation of the photometer, with one of the tables and carriages.

Having sufficiently explained all the essential parts of this photometer, it remains for us to give some account of the precautions necessary to be observed in using it. And, first, with respect to the distance at which lights, whose intensities are to be compared, should be placed from the field of the instrument, the ingenious and accurate inventor found, that when the weakest of the lights in question is about as strong as a common wax candle, that light may most advantageously be placed from 30 to 36 inches from the centre of the field; and when it is weaker or stronger, proportionally nearer or farther off. When the lights are too near, the shadows will not be well defined; and when they are too far off, they will be too weak.

It will greatly facilitate the calculations necessary in drawing conclusions from experiments of this kind, if some steady light, of a proper degree of strength for that purpose, be assumed as a standard by which all others may be compared. Our author found a good Argand's lamp much preferable for this purpose to any other lamp or candle whatever. As it appears, he says, from a number of experiments, that the quantity of light emitted by a lamp, which burns in the same manner with a clear flame, and *without smoke*, is in all cases as the quantity of oil consumed, there is much reason to suppose, that, if the Argand's lamp be so adjusted as always to consume a given quantity of oil in a given time, it may then be depended on as a just standard of light.

In order to abridge the calculations necessary in these inquiries, it will always be advantageous to place the standard-lamp at the distance of 100 inches from the photometer, and to assume the intensity of its light at its source equal to unity; in this case (calling this standard light A, the intensity of the light at its source $= x = 1$, and the distance of the lamp from the field of the photometer $= m = 100$), the intensity of the illumination at the field of the photometer $(= \frac{x}{m^2})$ (See Lamp, p. 67. of this volume) will be expressed by the fraction $\frac{1}{100^2} = \frac{1}{10000}$; and the relative intensity of any other light, which is compared with it, may be found by the following proportion: Calling this light B, putting $y =$ its intensity at its source, and $n =$ its distance from the field of the photometer, expressed in English inches, as it is $\frac{y}{n^2} = \frac{x}{m^2}$, as was shewn in the article Lamp, referred to; or, instead of $\frac{x}{m^2}$, writing its value $= \frac{1}{10000}$, it will be $\frac{y}{n^2} = \frac{1}{10000}$; and consequently y is to 1 as n^2 is to 10000; or the intensity of the light B at its source, is to the intensity of the standard light A at its source, as the square of the distance of the light B from the middle of the field of the instrument, expressed in inches, is to 10000; and hence it is $y = \frac{n^2}{10000}$.

Or, if the light of the sun, or that of the moon, be compared with the light of a given lamp or candle C, the result of such comparison may best be expressed in words, by saying, that the light of the celestial luminary in question, *at the surface of the earth*, or, which is the same thing, at the field of the photometer, is equal to the light of the given lamp or candle, *at the distance found by the experiment*; or, putting $a =$ the intensity of the light of this lamp C at its source, and $p =$ its distance, in inches, from the field, when the shadows corresponding to this light, and that corresponding to the celestial luminary in question, are found to be of equal densities, and putting $z =$ the intensity of the rays of the luminary at the surface of the earth, the result of the experiment may be expressed thus, $z = \frac{a}{p^2}$; or the real value of a being determined by a particular experiment, made expresly for that purpose with the standard lamp, that value may be written instead of it. When the standard-lamp itself is made use of, instead of the lamp C, then the value of A will be 1.

The Count's first attempts with his photometer were to determine how far it might be possible to ascertain,

by

by direct experiments, the certainty of the assumed law of the diminution of the intensity of the light emitted by luminous bodies; namely, that the intensity of the light is everywhere as the squares of the distances from the luminous body inversely. As it is obvious that this law can hold good only when the light is propagated through perfectly transparent spaces, so that its intensity is weakened merely by the divergency of its rays, he instituted a set of experiments to ascertain the transparency of the air and other mediums

With this view, two equal wax. candles, well trimmed, and which were found, by a previous experiment, to burn with exactly the same degree of brightness, were placed *together*, on one side, before the photometer, and their united light was counterbalanced by the light of an Argand's lamp, well trimmed, and burning very equally, placed on the other side over against them. The lamp was placed at the distance of 100 inches from the field of the photometer, and it was found that the two burning candles (which were placed as near together as possible, without their flames affecting each other by the currents of air they produced) were just able to counterbalance the light of the lamp at the field of the photometer, when they were placed at the distance of 60,8 inches from that field. One of the candles being now taken away and extinguished, the other was brought nearer to the field of the instrument, till its light was found to be just able, singly, to counterbalance the light of the lamp; and this was found to happen when it had arrived at the distance of [illegible] In this experiment, as the candles burnt [illegible] brightness, it is evident that the intensities [illegible]ted and single lights were as 2 to 1, and in [illegible]tion ought, according to the assumed theo[illegible]ares of the distances, 60,8 and 43,4, to be; and, in fact, $\overline{60,8}^2 = 3696,64$ is to $\overline{43,4}^2 = 1883,56$ as 2 is to 1 very nearly.

Again, in another experiment, the distances were,

With two candles = 54 inches. Square = 2916

With one candle = 38,6 - - = 1489,96

Upon another trial,

With two candles = 54,6 inches. Square = 2981,16

With one candle = 39,7 - - = 1576,09

And, in the fourth experiment,

With two candles = 58,4 inches. Square = 3410,56

With one candle = 42,2 - - = 1780,84

And, taking the mean of the results of these four experiments,

	Squares of the Distances With two Candles.		With one Candle.
In the Experiment N° 1.	3696,64	—	1883,56
N° 2.	2916	—	1489,96
N° 3.	2981,16	—	1576,09
N° 4.	3410,56	—	1780,84
	4) 13004,36		4) 6730,45
Means	3251,09	and	1682,61

which again are very nearly as 2 to 1.

With regard to these experiments, it may be observed, that were the resistance of the air to light, or the diminution of the light from the imperfect transparency of air, sensible within the limits of the inconsiderable distances at which the candles were placed from the photometer, in that case the distance of the two equal lights united ought to be, to the distance of one of them single, in a ratio less than that of the square root of 2 to the square root of 1. For if the intensity of a light emitted by a luminous body, *in a space void of all resistance*, be diminished in the proportion of the squares of the distances, it must of necessity be diminished in a still higher ratio when the light passes thro' a resisting medium, or one which is not perfectly transparent; and from the difference of those ratios, namely, that of the squares of the distances, and that other higher ratio found by the experiment, the resistance of the medium might be ascertained. This he took much pains to do with respect to air, but did not succeed; the transparency of air being so great, that the diminution which light suffers in passing through a few inches, or even through several feet of it, is not sensible.

Having found, upon repeated trials, that the light of a lamp, properly trimmed, is incomparably more equal than that of a candle, whose wick, continually growing longer, renders its light extremely fluctuating, he substituted lamps to candles in these experiments, and made such other variations in the manner of conducting them as he thought bid fair to lead to a discovery of the resistance of the air to light, were it possible to render that resistance sensible within the confined limits of his machinery. But the results of them, so far from affording means for ascertaining the resistance of the air to light, do not even indicate any [illegible] the contrary, it might almost be inf[illegible] them, that the intensity of the ligh[illegible] minous body in air is diminished in a [illegible] of the squares of the distances; but as such a conclusion would involve an evident absurdity, namely, that light moving in air, its absolute quantity, instead of being diminished, actually goes on to *increase*, that conclusion can by no means be admitted.

Why not? Theories must give place to facts; and if this fact can be fairly ascertained, instead of rejecting the conclusion, we ought certainly to rectify our notions of light, the nature of which we believe no man fully comprehends. Who can take it upon him to say, that the substance of light is not latent in the atmosphere, as heat or caloric is now acknowledged to be latent, and that the agency of the former is not called forth by the passage of a ray through a portion of air, as the agency of the latter is known to be excited by the combination of oxygen with any combustible substance? See Chemistry, n° 293, *Suppl.*

The ingenious author's experiments all conspired to shew that the resistance of the air to light is too inconsiderable to be perceptible, and that the assumed law of the diminution of the intensity of light may be depended upon with safety. He admits, however, that means may be found for rendering the air's resistance to light apparent; and he seems to have thought of the very means which occurred for this purpose to M. de Saussure.

That eminent philosopher, wishing to ascertain the transparency of the atmosphere, by measuring the distances at which determined objects cease to be visible, perceived at once that his end would be attained if he should find objects of which the disappearance might be accurately determined. Accordingly, after many trials, he found that the moment of disappearance can be observed with much greater accuracy when a black

Photometer.

object is placed on a white ground, than when a white object is placed on a black ground; that the accuracy was still greater when the observation was made in the sun than in the shade; and that even a still greater degree of accuracy was obtained, when the white space surrounding a black circle, was itself surrounded by a circle or ground of a dark colour. This last circumstance was particularly remarkable, and an observation quite new.

If a circle totally black, of about two lines in diameter, be fastened on the middle of a large sheet of paper or pasteboard, and if this paper or pasteboard be placed in such a manner as to be exposed fully to the light of the sun, if you then approach it at the distance of three or four feet, and afterwards gradually recede from it, keeping your eye constantly directed towards the black circle, it will appear always to decrease in size the farther you retire from it, and at the distance of 33 or 34 feet will have the appearance of a point. If you continue still to recede, you will see it again enlarge itself; and it will seem to form a kind of cloud, the darkness of which decreases more and more according as the circumference becomes enlarged. The cloud will appear still to increase in size the farther you remove from it; but at length it will totally disappear. The moment of the disappearance, however, cannot be accurately ascertained; and the more experiments were repeated the more were the results different.

M. de Saussure, having reflected for a long time on the means of remedying this inconveniency, saw clearly, that, as long as this cloud took place, no accuracy could be obtained; and he discovered that it appeared in consequence of the contrast formed by the white parts which were at the greatest distance from the black circle. He thence concluded, that if the ground was left white near this circle, and the parts of the pasteboard at the greatest distance from it were covered with a dark colour, the cloud would no longer be visible, or at least almost totally disappear.

This conjecture was confirmed by experiment. M. de Saussure left a white space around the black circle equal in breadth to its diameter, by placing a circle of black paper a line in diameter on the middle of a white circle three lines in diameter, so that the black circle was only surrounded by a white ring a line in breadth. The whole was pasted upon a green ground. A green colour was chosen, because it was dark enough to make the cloud disappear, and the easiest to be procured.

The black circle, surrounded in this manner with white on a green ground, disappeared at a much less distance than when it was on a white ground of a large size.

If a perfectly black circle, a line in diameter, be pasted on the middle of a white ground exposed to the open light, it may be observed at the distance of from 44 to 45 feet; but if this circle be surrounded by a white ring a line in breadth, while the rest of the ground is green, all sight of it is lost at the distance of only 15½ feet.

According to these principles M. de Saussure delineated several black circles, the diameters of which increased in a geometrical progression, the exponent of which was $\frac{3}{2}$. His smallest circle was $\frac{1}{5}$ or 0·2 of a line in diameter; the second 0·3; the third, 0·45; and so on to the sixteenth, which was 87·527, or about 7 inches 3½ lines. Each of these circles was surrounded by a white ring, the breadth of which was equal to the diameter of the circle, and the whole was pasted on a green ground.

M. de Saussure, for his experiments, selected a straight road or plain of about 1200 or 1500 feet in circumference, which towards the north was bounded by trees or an ascent. Those who repeat them, however, must pay attention to the following remarks: When a person retires backwards, keeping his eye constantly fixed on the pasteboard, the eye becomes fatigued, and soon ceases to perceive the circle; as soon therefore as it ceases to be distinguishable, you must suffer your eyes to rest; not, however, by shutting them, for they would when again opened be dazzled by the light, but by turning them gradually to some less illuminated object in the horizon. When you have done this for about half a minute, and again directed your eyes to the pasteboard, the circle will be again visible, and you must continue to recede till it disappear once more. You must then let your eyes rest a second time in order to look at the circle again, and continue in this manner till the circle becomes actually invisible.

If you wish to find an accurate expression for the want of transparency, you must employ a number of circles, the diameters of which increase according to a certain progression; and a comparison of the distances at which they disappear will give the law according to which the transparency of the atmosphere decreases at different distances. If you wish to compare the transparency of the atmosphere on two days, or in two different places, two circles will be sufficient for the experiment.

According to these principles, M. de Saussure caused to be prepared a piece of white linen cloth eight feet square. In the middle of this square he sewed a perfect circle, two feet in diameter, of beautiful black wool; around this circle he left a white ring two feet in breadth, and the rest of the square was covered with pale green. In the like manner, and of the same materials, he prepared another square; which was, however, equal to only $\frac{1}{12}$ of the size of the former, so that each side of it was 8 inches; the black circle in the middle was two inches in diameter, and the white space around the circle was 2 inches also.

If two squares of this kind be suspended vertically and parallel to each other, so that they may be both illuminated in an equal degree by the sun; and if the atmosphere, at the moment when the experiment is made, be perfectly transparent, the circle of the large square, which is twelve times the size of the other, must be seen at twelve times the distance. In M. de Saussure's experiments the small circle disappeared at the distance of 314 feet, and the large one at the distance of 3588 feet, whereas it should have disappeared at the distance of 3768. The atmosphere, therefore, was not perfectly transparent. This arose from the thin vapours which at that time were floating in it. M. de Saussure, as we have observed, calls his instrument a *diaphanometer*; but as it answers one of the purposes of a photometer, we trust our readers will not consider this account of it as a digression.

To return to Count Rumford. From a number of experiments made with his *photometer*, he found that, by passing through a pane of fine, clear, well polished glass, such as is commonly made use of in the construction of looking-glasses, light loses ,1973 of its whole quantity,

quantity, *i. e.* of the quantity which impinged on the glafs; that when light is made to pafs through two panes of fuch glafs ftanding parallel, but not touching each other, the lofs is ,3184 of the whole; and that in paffing through a very thin, clear, colourlefs pane of window-glafs, the lofs is only ,1263. Hence he infers, that this apparatus might be very ufefully employed by the optician, to determine the degree of tranfparency of glafs, and direct his choice in the provifion of that important article of his trade. The lofs of light when reflected from the very beft plain glafs mirror, the author afcertained, by five experiments, to be $\frac{1}{3}$d of the whole which fell upon the mirror.

PIANO FORTE, otherwife called FORTE PIANO, a well-known mufical inftrument, of which we need make no apology for confidering the peculiarities with fome attention. If we look on mufic from no higher point of view than as the *laborum dulce lenimen*, the innocent, the foothing, the chearing fweetener of toil, we muft acknowledge that it is far from being the meaneft of thofe enjoyments with which the Bountiful Father of Men has embellifhed this fcene of our exiftence. But there is a *fcience* in mufic, independent of that artificial half mathematical doctrine which we have contrived to unite with it, and which really enables us to improve pure mufical pleafure. Hence in the Englifh univerfities degrees are conferred in mufic.

The voice [illegible] inftrument, and all others [illegible] The voice of man obeys the impulfe of [illegible] promptitude, and [illegible] very coarfe ear is [illegible] to what is called [illegible] melodies extending to 12 notes [illegible]. The motion of the glottis [illegible] does not amount to [illegible]th of an inch [illegible] therefore be divided, by the moft [illegible] more than a thoufand parts; and this [illegible] in an inftant, and repeated with [illegible] miftaking one of thefe divifions; and this is [illegible]where, and without any feeming effort or thought. The mechanifm of the human organ for effecting this with eafe and precifion is very remarkable, and feems to prove that the Author of our Being meant to give us this pleafure.

When, in the cultivation of this fruit of our own foil, the moderns difcovered the beauties of harmony or confonance, and inftruments of fixed founds were employed, by means of which thefe beauties could be exhibited in their utmoft richnefs and variety; and particularly when the organ, that "magic world of found," was invented, the immenfe advantages of the ingenious fpeculations of the ancient Greeks about the divifion of the monochord were now perceived, and mufic became a deep intellectual ftudy. It fell into the hands of men of letters, and, for a long while, counterpoint occupied all their attention. Inftruments of fixed founds were now made, not only with pipes, but with ftrings, bells, rings, and every thing that could make a noife in tune.

But all thefe inftruments were far inferior to the voice, the fpontaneous gift of Nature, in promptitude, and in the power of obeying every call of fentiment, every degree, as well as every kind of emotion, with which the heart was agitated. The pleafures of harmony, though great, were monotonous, and could not exprefs the momentary variations of fentiment, which are as fleeting as the light and fhade of a profpect while the dappled clouds fail acrofs the fky. The violin, and a fmall number of the fimple wind inftruments, were found to be the only ones which could fully exprefs thofe momentary gradations of fentiment that give mufic its pathos, and enable it to thrill the very foul.

Piano Forte.

Attempts were made to remove this defect of the harmonic inftruments, and the SWELL was added to the organ. The effect was great, and encouraged the artifts to attempt fimilar improvements on other inftruments of the fame kind. This was firft done in the fame way as in the organ. The harpfichord was fhut up, like the fwell organ, and was opened by means of pedals when the performer wifhed to enforce the found. But the effect was far inferior to that of the fwell organ; for this was (at leaft in all great organs) a real addition of another properly felected found. But the effect of the pedal on the harpfichord could not be miftaken; it was juft like opening the door of a room where mufic was performing. Other methods were tried with better effect. Unifons were added to each note, which were brought on either by means of pedals or by another fet of keys.

This method fucceeded perfectly well, and the power of the harpfichord was greatly improved. But ftill it was imperfect, becaufe it was only the more confiderable changes of force which could be exhibited, and this only in one or two degrees. Other artifts, therefore, attempted to conftruct the inftrument, fo that the jacks (the moveable upright pieces which carry the quills) can be made to approach nearer to the wires, fo that the quills fhall give them a ftronger twang. The mechanifm was fuch, that a very confiderable motion of the pedal produced but a moft minute motion of the quill; fo that the performer was not reftricted to the utmoft precifion in the degree of preffure. Some of thofe inftruments, when frefh from the hand of the artift, gave full fatisfaction. But, though made in the moft accurate manner, at an enormous expence, they very foon become unfit for the purpofe. The hundredth part of an inch, more or lefs, in the place of the quill, will make a great odds in the force of the found. Nor does the fame change of diftance produce an equal alteration of found on different quills. Other inftrument makers have therefore tried baked or prepared leather (buffalo hide) in place of quills; and it is found much more uniform in the tone which it produces, and alfo remains longer in the fame ftate; but the tone is not fo powerful, nor in general fo much relifhed.

But all thefe contrivances, both in the organ and harpfichord, were ftill very deficient. Whatever change they could produce in the ftrength of the found, was produced through the whole inftrument, or at leaft through two or three octaves. But the captivating expreffion of mufic frequently refults from the momentary fwelling or foftening of a fingle phrafe, or a fingle note, in one of the parts. Hence arife the unrivalled powers of the harp, and the acknowledged fuperiority of the theorbo, the lute, and even the guitar, over all keyed inftruments, notwithftanding their great limitations in harmony and in practicable melodies. Thefe inftruments fpeak, while the harpfichord only plays.

Many attempts have been made to enable the performer to produce, by the intervention of the key, all the gradations of ftrength, and even the varieties of

 found,

sound, which the finger can bring forth by the different manner of pinching, brushing, or, as it were, caressing the string; but we have no distinct account of any attempt that has succeeded. Such a thing would quickly spread over Europe. The compiler of the article LUTHIER, in the *Encyclopedie Methodique*, says a great deal about a harpsichord fitted with prepared buffalo leather instead of crow quills; and asserts expressly, that, by the mere pressure on the key, without the assistance of pedals or stops of any kind, the leather is made to act with greater or less force on the string. But he gives no account by which we can comprehend how this is brought about; and indeed he writes in terms which shew plainly that he has not seen the instrument, and is merely puffing something that he does not understand.

The attempt has been made with more success on keyed instruments, when the strings are not pinched, but are rubbed by a wheel or band, in the manner of the vielle (hurdygurdy), or struck with a plectrum, like the dulcimer. The CELESTINA (described by Mersennus by the name of ARCHIVIOLA) is of this kind. A fine band of horse hair or silk, filled with rosin, is extended under the strings, and drawn smoothly along by a wheel. By a particular mechanism of the keys, this band is made to press or rub on any string transversely, as the strings of a violin are touched by the bow. The pressure on the key regulates the strength of the tone. This instrument is not without considerable beauties, and will execute soft *cantabile* music in easy modulation, with great expression and justness. But the artists have not yet been able to give it either clearness or brilliancy of tone, nor sufficient force for concert music, nor that promptitude of touch that is indispensably necessary for figurative music or quick movements.

The same improvements have been made on the pulsatile instruments; and indeed they are here the most obvious and easy. When the key is employed merely as the means of causing a plectrum to give a blow to the string, the performer will hardly fail to give that degree of force which he feels proper for his intended expression. Accordingly, many instruments of this kind have been made in Germany, where the artists have long been eminent for mechanical knacks. But all their instruments of the dulcimer kind are feeble and spiritless, and none of them have been brought into general use, if we except the CLAVICHORD. This is indeed an instrument of feeble, and not the most pleasing sound; but is well fitted for giving every momentary gradation of strength by the pressure of the finger. Is is therefore a good instrument for forming the musical taste by chamber practice, and was much used by compositors in their studies. It is also an ingenious, though seemingly an obvious and simple contrivance, and is capable of much more force, and even brilliancy of sound, than has generally been given to it.

The construction is shortly this. The inner end of the key is furnished with an upright piece, which terminates in an edge of brass, somewhat like the end of a narrow blunt chisel, whose line of direction is athwart the strings. When the key is pressed down, this edge strikes the string, and forces it out of the straight line in which it is stretched between its pins. Thus the string is shaken or jogged into vibration, in the same manner as we observe a tight rope set a vibrating by a sudden jerk given to any part of it. The string, thus agitated, gives a sound, which will continue for some little time if the key be held down. As the tone depends on the length of the vibrating string, as well as on its tension, it is of importance that the stroke be made on the precise point of the string which terminates the proper length. The string does not give the note corresponding to its whole length, but that which is produced by the part between the edge and the pin. And because the parts of the string on each side of the edge are equally thrown into vibration, the shorter portion of it must be wrapped up in a list of cloth, to prevent it from disturbing the ear by its sonorous vibrations. This, however, greatly diminishes the sweetness of the sound given by the other part.

The clavichord gives a fretful waspish kind of sound, not at all suited to tender expression. If the bridge (for the end of the key is really a bridge during the sound) were placed at an exact third of the length of the string, and if both parts were free, and if the stroke be of a proper strength, the string would sound its twelfth with great sweetness, and with much more force and brilliancy than it does by the present construction, and the clavichord would be a charming instrument for a lesson and for private study. We say this from experience of the power of one constructed under the direction of the great mathematician Euler, who was also an excellent judge of music and musical composition. The tones of the upper part of that instrument had a sort of pipe or vocal sound, and were superior in clearness and sweetness to any stringed instrument we ever heard. But as this construction required every string to be one half longer than a harpsichord wire of the same pitch, and as this would have made the instrument of a most inconvenient size, the basses were made shorter, by placing the bridge at one-sixth of the length, and loading the shorter portion of the string with wire twisted round it. But although this was executed by a most dexterous artist, the tones were far inferior to those of the trebles, and the instrument was like the junction of a very fine one and a very bad one, and made but hobbling music. This was probably owing to the impossibility of connecting the metal wire and its covering with sufficient closeness and solidity. An upright clavichord, where the length would be no inconvenience, would be indeed a capital instrument for musical study. It is worthy of remark, that Mr Euler tried other divisions of the string by the bridge. When it is struck precisely in the middle, it should sound its octave; when it is struck at one-fourth, it should give the double octave, &c. But the maker found that these divisions gave very indifferent, and even uncertain tones; sometimes not sounding at all, and sometimes sounding beautifully. Our readers will find this well explained in a future article of this *Supplement*, (TRUMPET, *Marine*). They may please to reflect on the very different tone of the violin as it is bowed on different parts of the string, and on the very different tones of the fore and back unisons, and particularly of the Cornet stop of the harpsichord. The harpsichords of Rucker are noted for the grand fulness of their tone; those of Hasse of Dresden for their mellow sweetness, and those of Kirkmann of London for their unequalled brilliancy. These makers differed greatly in the placing of their quills.

But the English PIANO FORTE, by its superior force of tone, its adequate sweetness and the great variety of voice of which our artists have made it susceptible, has with-

withdrawn all farther attention from the clavichord, ſo that it is no longer probable that the learned contribution of the great Euler to public amuſement will be followed up. The Piano forte correſponds to its name with great preciſion: For, without any other attention or effort than what ſentiment ſpontaneouſly dictates, and what we practiſe (without knowing it) on the harpſichord, where it is ineffectual, we make the Piano-forte give every gradation of ſtrength to the ſound of the ſtring, and give it every expreſſion that an inſtrument, purely pulſatile, is capable of. It is alſo ſuſceptible of a very conſiderable variety of tone by the clothing of the mallets, which may be acute or obtuſe, hard or ſoft. And we ſee, by the effect of what are called the grand Piano fortes, that they are fully equal to the harpſichord in fulneſs or body of tone. Nothing ſeems to be wanting to it but that ſliding, or (as the French call it) *careſſing* touch of the ſtring, by which a delicate finger, guided by fine taſte, cauſes the harp or lute to melt the heart, and excite its fineſt emotions. We truſt that the ingenuity of our Britiſh artiſts will accompliſh even this, and make this national inſtrument rival even the violin of Italy.

We call it a *national inſtrument*, not doubting but that this is a recommendation to a Britiſh heart, and becauſe we are very well aſſured that it is an Engliſh contrivance; the invention of a moſt excellent man and celebrated poet, Mr William Maſon. His Caractacus and Elfrida may convince any perſon who is a judge of muſic, that he had a mind exquiſitely ſenſible of all its charms; and we cannot be ſurpriſed that it was one of his chief delights. No man enjoyed the pleaſures of muſic with more rapture; and he uſed to ſay, that his ſpeedieſt recruit from the fatigue of a long walk was to ſit down for a few minutes to the harpſichord. He had ſeen ſeveral of the German attempts to make keyed dulcimers, which were, in ſome meaſure, ſuſceptible of the *forte* and *piano*; But they were all on one principle, and required a particular touch of the finger, of difficult acquiſition, and which ſpoiled the harpſichord practice. We have alſo ſeen of thoſe inſtruments, ſome of very old date, and others of modern improvement. Some had very agreeable tones; but all were deficient in delicacy and juſtneſs. The performer was by no means certain of producing the very ſtrength of ſound that he intended. And, as Mr Maſon obſerved, they all required an artificial peculiarity of fingering; without which, either the intended ſtrength of tone was not brought out, or the tone was deſtroyed by repeated rattling of the mallet on the wire.

Mr Maſon removed all thoſe imperfections by detaching the mallet entirely from the key, and giving them a connection quite momentary. The ſketch in Plate XL. will give the reader a clear view of Mr Maſon's general principle, by which the Engliſh piano forte is diſtinguiſhed from all others. The parts are repreſented in their ſtate of inaction. The key ABK turns, as uſual, on the round edge of the bar B, and a pin *b*, driven into the bar, keeps it in its place. The dot F repreſents a ſection of the ſtring. ED is the mallet, having a hinge of vellum, by which it is attached to the upper ſurface of the bar E. At the other end is the head D, of wood, covered with ſome folds of prepared leather. The mallet lies in the poſition repreſented in the figure, its lower end reſting on a cuſhion-bar K, which lies horizontally under the whole row of mallets. The key AR has a pin C, tipt with a bit of the ſofteſt cork or buckſkin. This reaches to within $\frac{1}{10}$th of an inch of the ſhank of the mallet, but muſt not touch it. The diſtance E*e* is about $\frac{1}{3}$d or $\frac{1}{4}$th of the length of the ſhank. When the end A of the key is preſſed down on the ſtuffing (two or three thickneſſes of the moſt elaſtic woollen liſt) it raiſes the mallet, by means of the pin C, to the horizontal poſition E*d*, within $\frac{1}{8}$th or $\frac{1}{10}$th of an inch of the wire F; but it cannot be ſo much preſſed down as to make the mallet touch the wire. At the ſame time that the key raiſes the mallet by means of the pin C, it alſo lifts off the damper G (a bit of ſpunge) from the wire. This damper is fixed on the end of a little wooden pin G*g*, connected with the lever *g* H, which has a vellum hinge at H. This motion of the damper is cauſed by the pin I, which is fixed into the key near to R. Theſe pieces are ſo adjuſted, that the firſt touch of the key lifts the damper, and, immediately after, the pin C acts on the ſhank of the mallet. As it acts ſo near to its centre of motion, it cauſes the head D to move briſkly through a conſiderable arch D*d*. Being made extremely moveable, and very light, it is thus *toſſed* beyond the horizontal poſition E*d*, and it ſtrikes the wire F, which is now at liberty to vibrate up and down, by the previous removal of the damper G. Having made its ſtroke, the mallet falls down again, and reſts on the ſoft ſubſtance on the pin C. It is of eſſential importance that this mallet be extremely light. Were it heavy, it would have ſo much force, after rebounding from the wire, that it would rebound again from the pin C, and again ſtrike the wire. For it will be recollected, that the key is, at this time, down, and the pin C raiſed as high as poſſible, ſo that there is very little room for this rebound. Leſſening the momentum of the mallet by making it very light, making the cuſhion on the top of the pin C very ſoft, and great preciſion in the ſhape and figure of all the parts, are the only ſecurities againſt the diſagreeable rattling which theſe rebounds would occaſion. In reſpect to the ſolidity and preciſion of workmanſhip, the Britiſh inſtruments are unrivalled, and vaſt numbers of them are ſent to all parts of the continent.

As the blow of ſo light a mallet cannot bring much ſound from a wire, it has always been found neceſſary to have two ſtrings for each note. Another circumſtance contributes to enfeeble the ſound. The mechaniſm neceſſary for producing it makes it almoſt impoſſible to give any conſiderable extent to the belly or ſound board of the inſtrument. There is ſeldom any more of it than what occupies the ſpace between the tuning pins and the bridge. This is the more to be regretted, becauſe the baſſes are commonly covered ſtrings, that they may be of a moderate length. The baſs notes are alſo of braſs, which has a conſiderably lower tone than a ſteel wire of the ſame diameter and tenſion. Yet even this ſubſtitution for ſteel in the baſs ſtrings is not enough. The higheſt of them are much too ſlack, and the loweſt ones muſt be loaded, to compenſate for want of length. This greatly diminiſhes the fulneſs, and ſtill more the mellowneſs and diſtinctneſs of the tone, and frequently makes the very loweſt notes hardly appreciable. This inequality of tone about the middle of the inſtrument is ſomewhat diminiſhed by conſtructing the inſtrument with two bridges; one for the ſteel, and the other for the braſs wires. But ſtill the

Piano Forte

the bafs notes are very much inferior to the treble. It would furely be worth while to conftruct fome piano fortes, of full fize, with naked baffes. If thefe were made with all the other advantages of the grand piano forte, they would furpafs all other inftruments for the regulating power of their thorough bafs. We wifh that the artifts would alfo try to conftruct them with the mechanifm of mallets, &c. above the found board. This would allow to it the full extent of the inftrument, and greatly improve the tone. It does not feem impoffible, nor (we think) very difficult.

For directions how to tune this pleafing inftrument, fee TEMPERAMENT in this *Supplement*.

PIGMENTS, or PAINTS, are furnifhed by both the mineral and vegetable kingdoms. The former are the moft durable, and are generally prepared from the OXYDS of metals (fee CHEMISTRY-*Index* in this *Suppl.* and *Colour-Making*, Encycl.); but Fourcroy thinks that chemiftry furnifhes a method of fixing vegetable colours completely. From a number of experiments, which we need not detail, as they will be noticed in the article *Vegetable* SUBSTANCES, he draws the following conclufions:

1. That oxygen, when combined with vegetable fubftances, changes their colour.

2. That different proportions of this principle produce different fhades in coloured vegetable matter.

3. That thefe fhades pafs, by a fort of degradation, from the darkeft colours to the lighteft; and that the extreme point of the latter may be confidered as a complete deprivation of colour.

4. That in many vegetable fubftances this degradation does not take place, as M. Berthollet has obferved.

5. That many red, violet, purple, chefnut, and blue vegetable colours, are produced by different proportions of oxygen; but that none of thefe are completely faturated with this principle.

6. That the complete faturation here fpoken of generally produces yellow colours, which are the leaft changeable of all.

7. That vegetable fubftances coloured by oxygen, not only change their colour according to the proportion of oxygen they have imbibed, but that they alfo change their nature in the fame proportion, and approach more to a refinous ftate as they become nearer to a yellow colour.

Laftly, that the caufe of the changeability of the red, brown, and violet colours, procured from vegetables, is fuch as has been ftated above; that there exifts a method of fixing them, or rendering them permanent, by impregnating them with a certain quantity of oxygen, by means of the oxygenated muriatic acid; imitating, by this procefs, the method purfued by nature, who never forms fixed and permanent colours, except in fubftances which have been long expofed to the open air.

PITCH. See *Encycl.*—The beft black pitch is made of the refufe of rofin and turpentine, fuch as will not pafs through the ftraw filter, and the cuttings around the incifion on the tree. Thefe materials are put into a boiler fix or feven feet in circumference, and eight or ten high. Fuel is laid around the top, and the materials as they melt flow through a channel cut in the fire-place into a tub half filled with water. It is at that time very red, and almoft liquid. To give this a proper confiftence, it is put in a cauldron placed in a furnace, and boiled down in the fame manner as rofin, but it requires much lefs precaution and double the time. It is then poured into moulds of earth, and forms the beft kind of black pitch. See ROSIN and TURPENTINE in this *Suppl.*

BASTARD PITCH, is a mixture of colophony, black pitch, and tar. They are boiled down together, and put into barrels of pine wood, forming, when the ingredients are mixed in equal portions, a fubftance of a very liquid confiftence, called in France *bray gras*. If, on the contrary, it is defired of a thicker confiftence, a greater proportion of colophony is added, and it is caft in moulds. It is then called *baftard pitch*.

PLAGUE (fee MEDICINE-*Index*, Encycl.), is a difeafe which has been lately afferted by Dr Mofeley to be not contagious. In fupport of this opinion, he quotes many paffages from medical writers, ancient and modern; but he feems to place the greateft confidence (as is indeed natural) in his own obfervations on peftilential fevers in the Weft Indies, and on what is faid of the plague in Berthier's account of Buonaparte's expedition into Syria.

"At [illegible] (fays this Frenchman), [illegible] a malady [illegible] in the [illegible] felves up [illegible] every [illegible] have [illegible]

"Citizen De[illegible] phyfician to the army, [illegible] entitle him to [illegible] were attacked [illegible] had [illegible] founded [illegible] by the officers [illegible] Citizen Degenettes [illegible] vifited all the patients, felt the [illegible] fwellings, dreffed them, declared and maintained that the diftemper was not the plague, but a malignant fever with glandular fwellings, which might eafily be cured by attention, and keeping the patient's mind eafy."

Degenette's views in making this diftinction were highly commendable; but certainly, fays Dr Mofeley, this fever was the plague. The phyfician, however, carried his courage fo far, as to make two incifions, and to inoculate the fuppurated matter from one of thefe buboes above his breaft and under his arm-pits, but was not affected with the malady. He thus eafed the minds of the foldiers, the firft ftep to a cure; and, by his affiduity and conftant attendance in the hofpitals, a number of men attacked with the plague were cured. His example was followed by other officers of health.

The lives of a number of men Citizen Degenettes was

(A) This can hardly be true. Every one knows that Mahometans are fatalifts in the ftricteft fenfe of the word; and Mr Browne, whofe knowledge of Syria and its inhabitants muft be at leaft equal to that of Berthier, affures us, that, far from abandoning his friend in the plague, "the Moflem, awe-ftruck, and refigned to the unalterable decrees of fate, hangs over the couch of his expiring relative."

Plague.

was thus inftrumental of faving. He difmiffed thofe who had been ill with the fever and buboes, without the leaft contagion being communicated to the army.

"There are (fays Dr Mofeley) annual or feafonal diforders, more or lefs fevere, in all countries; but the plague, and other great depopulating epidemics, do not always obey the feafons of the year. Like comets, their courfe is eccentric. They have their revolutions; but from whence they come, or whither they go after they have made their revolutions, no mortal can tell.

"To look for the caufe of an epidemic in the prefent ftate of the air, or weather, when it makes its appearance, is a very narrow contracted method of fcrutiny. The caufe of peftilential epidemics cannnot be confined, and local. It muft lie in the atmofphere, which furrounds, and is in contact with every part of us; and in which we are immerfed, as bodies in fluids.

"Thefe difeafes not appearing in villages and thinly inhabited places, and generally attacking only great towns and cities, may be, that the atmofphere, which I conceive to be the univerfal propagator of peftilence, wants a commixture, or union, with fome compounded and peculiar air, fuch as is generated in populous communities, to releafe its imprifoned virulence, and give it force. Like the divided feminal principles of many plants, concealed in winds and rains until they find fuitable materials and foil to unite their feperated atoms, they then affume vifible forms in their own proper vegetation.

"Difeafes originating in the atmofphere feize fome, and pafs by others; and act exclufively on bodies graduated to receive their impreffions; otherwife whole nations would be deftroyed. In fome conftitutions of the body the accefs is eafy, in fome difficult, and in others impoffible.

"The air of confined places may be fo vitiated as to be unfit for the purpofes of the healthy exiftence of any perfon. Hence gaol, hofpital, and fhip fevers. But as thefe diftempers are the offspring of a local caufe, that local caufe, and not the diftempered people, communicate the difeafe.

"Plagues and peftilences, the produce of the great atmofphere, are conveyed in the fame manner, by the body being in contact with the caufe; and not by its being in contact with the effect. If peftilences were propagated by contagion, from infected perfons, the infection muft iffue from their breath or excrements, or from the exhalations of the bodies of the difeafed. The infection, if it were not in the atmofphere, would be confined within very narrow limits; have a determinate fphere of action; and none but phyficians and attendants on the fick would fuffer; and thefe muft fuffer; and the caufe and the effects would be palpable to our fenfes. Upon this ground the precaution of quarantine would be rational. But who then would vifit and attend the fick, or could live in hofpitals, prifons, and lazarettos?"

From thefe reafonings and facts, the author is convinced, that the bubo and carbuncle, of which we hear fo much in Turkey, and read fo much in our own hiftory of plagues, arife from heating food and improper treatment; that they contain no infection; and confequently that they are not the natural depofit of the morbific virus feparated from the contagion.

He is equally confident that no peftilential or pandemic fever was ever imported or exported; and hence he confiders the fumigating of fhip-letters, and fhutting up the crews and paffengers of veffels, on their arrival from foreign places, feveral weeks, for fear they fhould give difeafes to others which they have not themfelves, as an ignorant barbarous cuftom. Whence was the importation of the plague at Naples in 1656; by which 20,000 people died in one day? Can any perfon, for a moment reflecting, believe, that the great plague of London in 1665, which imagination traced from the Levant to Holland, and from Holland to England, was caufed by opening a bag of cotton in the city, or in Long Acre; or a package of hemp in St Giles's parifh? Quarantine, always expenfive to commerce, and often ruinous to individuals, is a reflection on the good fenfe of countries.

That Dr Mofeley is a man of learning, and a lively writer, is known to every one who has looked into his works, and is not himfelf a ftranger to letters. On this account, and ftill more on account of the opportunities which he has poffeffed of making accurate obfervations on various kinds of peftilential difeafes, we have detailed at fome length his notions of the plague; but as it does not appear that he ever *faw* the difeafe which is *known* by the name of *the plague*, juftice requires that we give fome account of it from a man who had the beft poffible opportunities of obtaining correct information on the fubject.

"The facts that appear to be chiefly afcertained relative to the plague (fays Mr Browne), are, 1. That the infection is not received but by actual contact. In this particular, it would feem lefs formidable than feveral other diforders. 2. That it is communicated by certain fubftances, by others not; as by a woollen cloth, or rope of hemp, but not by a piece of ivory, wood, or a rope made of the date tree; nor by any thing that has been completely immerfed in water. It would appear from the report of the Kahirines*, that no animal but man is affected with this diforder; though, it is faid, a cat paffing from an infected houfe has carried the contagion. 3. That perfons have often remained together in the fame houfe, and entirely under the fame circumftances, of whom one has been attacked and died, and the others never felt the fmalleft inconvenience. 4. That a perfon may be affected any number of times. 5. That it is more fatal to the young than the old 6. That no climate appears to be exempt from it; yet, 7. That the extremes of heat and cold both appear to be adverfe to it. In Conftantinople it is often, but far from being always, terminated by the cold of winter, and in Kahira by the heat of fummer; both circumftances being, as may be conjectured, the effect of indifpofition for abforption in the fkin, unlefs it be fuppofed that in the latter cafe it may be attributed to the change the air undergoes from the increafe of the Nile.

"The firft fymptoms are faid to be thirft; 2. cephalalgia; 3. a ftiff and uneafy fenfation, with rednefs and tumor about the eyes; 4. watering of the eyes; 5. White puftules on the tongue The more advanced fymptoms of buboes, fœtor of the breath, &c. &c. are well known; and I have nothing authentic to add to them. Not uncommonly, all thefe have fucceffively fhewn themfelves, yet the patient has recovered; in which cafe, where fuppuration has had place, the fkin always remains difcoloured, commonly of a purple hue. Many who have been bleeded in an early ftage of the diforder,

* The inhabitants of Cairo, which Mr Browne uniformly calls Kahira.

disorder, have recovered without any fatal symptoms; but whether from that or any other cause, does not appear certain (B). The same operation is reported to have been commonly fatal in a late stage. It is said that embrocating the buboes continually with oil has sometimes wrought a cure; but this remedy is so difficult and dangerous for the operator, that it would appear experiments must yet be very defective"

They are not, perhaps, so defective as Mr Browne supposes. In the hospital of St Anthony at Smyrna, it has been the practice for many years past to rub over with warm olive oil the bodies of persons infected by the plague; and that practice has been attended with wonderful success. It was first suggested by Mr Baldwin the English consul; and from him adopted by *P. Luigi di Pavia*, who for upwards of 27 years has exposed himself to infection by his unremitting attendance on those who are labouring under this dreadful distress. This excellent man, whose philanthropy equals that even of "Marseilles' good bishop," declares, that during the long period mentioned, he has found no remedy comparable to that of rubbing olive oil, with the strongest friction, into the whole body of the infected person. When the body is thus rubbed, the pores being opened, imbibe the oil, and a profuse perspiration takes place, by which the poisonous infection is again thrown out. This operation must be performed the first day of the infection; and if only a weak perspiration ensues, it must be repeated till it is observed that every particle of infection is removed, and that the whole body of the patient is covered with a profuse sweat. Neither the patient's shirt nor bed-clothes must be changed till the perspiration has entirely ceased. The operation must be performed in a very close apartment; and at every season of the year there must be kept in it a fire-pan, over which sugar and juniper must be thrown from time to time, that the vapour which thence arises may promote the perspiration. The whole body of the patient, the eyes alone excepted, must in this manner be anointed, or rather rubbed over with the greatest care.

This practice of the pious monk is mentioned by Mr Howard in his work on Lazarettos; but a more satisfactory account of it is given by Count *Leopold von Berchtold*, who adds the following remarks by way of illustration: 1. The operation of rubbing in the oil must be performed by means of a sponge, and so speedily as not to last more than about three minutes. 2. The interval between the first and the second rubbing, if a second be necessary, must be determined by circumstances, as the second must not be performed till the first perspiration is over, and this will depend on the constitution of the patient. If any sweat remains upon the skin, it must be wiped off with a warm cloth before the second rubbing takes place. This strong friction with oil may be continued, for several days successively, until a favourable change is remarked in the disease; after which the rubbing may be performed in a more gentle manner. The quantity of oil requisite each time cannot be determined with accuracy; but, in general, a pound may be sufficient. The purest and freshest oil is the best for this operation: it must not be hot, but only lukewarm. The breast and privities must be rubbed softly. In a cold climate such as ours, those parts only into which the oil is rubbed must be exposed naked. The other parts must be covered with warm clothing. In this manner each part of the body must be rubbed with oil in succession, as quickly as possible, and be then instantly covered. If the patient has boils or buboes, they must be rubbed over gently with the oil till they can be brought to suppurate by means of emollient plasters. The persons who attend the patients to rub in the oil must take the precaution to rub themselves over in the like manner, before they engage in the operation. They must, if possible, avoid the breath of the patient, and not be under any apprehensions of catching the infection.

P. Luigi then says, "In order to prevent the patients from losing their strength, I prescribed for them, during four or five days, soup made of vermicelli boiled in vinegar without salt. I gave them six or seven times a-day a small spoonful of preserved sour cherries; preserved not with honey, but with sugar, as the former might have occasioned a diarrhoea. When convinced that the patients were getting better, I usually gave them the fifth morning a cup of good Mocha coffee, with a piece of toasted biscuit (*biscotto*) prepared with sugar; and I doubled the latter according to the strength and improvement of my patients."

In the course of five years, during which friction with oil was employed in the hospital at Smyrna, of 250 persons attacked by the plague the greater part were

(B) Dr Mosely, we think, has assigned a very sufficient reason why bleeding should generally prove effectual, if recourse be had to it at the commencement of the disease. "In the common order of pestilential fevers (says he), they commence with coldness and shivering; simply demonstrating, that something unusual has been in contact with the skin, agonizing cutaneous sensibility. Sickness at the stomach, and an immoveable pressure about the præcordia, follow. These demonstrate, that the blood cannot pervade the extremities of the body, and that the quantity which ought to dilate through the whole machine is confined to the larger organs, and is crowding and distending the heart and central vessels.

"The restraining power of the remoter blood-vessels being destroyed, the thinner parts of the blood escape their boundaries; hence arises yellowness in the skin in some climates; in others, the extravasated grosser parts of the blood stagnate, forming black lodgements, bubo, anthrax, and exanthemata.

"The object in these fevers is, to decide the contest between the solids and the fluids; and this appears to me to be only practicable, when spontaneous sweats do not happily appear, or cannot be raised by a cooling regimen; and by draining the vital parts, by bleeding and purging, before the fluids have burst their confines, and dissolved their bond of union with the solids. The next step is to regain the lost energy of the surface of the body, by exciting perspiration; and then of the whole system, by tonics.

"When these things are not done in the first hours of attack, in pestilential fevers, and the conflict is not *extinguished* at once, attempting to extort sweats from the body, by heating alexapharmics, will do mischief; and bark, wine, stimulants, and cordials, may be called on, like undertakers, to perform an useless ceremony."

Plague, Plants.

were cured; and this would have been the case with the rest had they not neglected the operation, or had it not been employed too late after their nervous system had been weakened by the disease so as to render them incurable. Immense numbers of people have been preserved from the effects of this malady by the above means; and of all those who have anointed themselves with oil, and rubbed it well into their bodies, not one has been attacked by the plague, even though they approached persons already infected, provided they abstained from heavy and indigestible food.

Thus we see, if this account may be depended on, that oil rubbed into the skin acts as a preventative, as well as a cure. When the operation is performed to prevent infection, and it is successfully performed with that view at Smyrna, as often as the plague makes its appearance in the city, as it is not done for the purpose of promoting perspiration, it is not requisite that it should be performed with the same speed as when for curing the disorder; nor is it necessary to abstain from flesh and to use soups; but it will be proper to use only fowls or veal for ten or twelve days, boiled or roasted, without any addition or seasoning *(condimento)*. In the last place, it will be necessary to guard against fat and indigestible food, and such liquors as might put in motion or inflame the mass of the blood.

This important discovery deserves the serious consideration of all medical men; for if olive oil has been found efficacious in curing or preserving against one species of infection, it is not absurd to suppose that the same or other kinds of oil might be productive of much benefit in other malignant infectious diseases. We hope soon to hear of some trial being made with it in this country. Would it be of any service in the yellow fever, so prevalent in the western world? See the *Philosophical Magazine*, Vol. II.

PLANETARY HOURS, are twelfth parts of the artificial day and night; being each double in length to the hour used in civil computation in Europe. They are still used by the Jews as they were among their forefathers; and hence are called Jewish hours. The reason of their being called *planetary* hours, is that, according to the astrologers, a new planet comes to predominate every hour, and that the day takes its denomination from that which predominates the first hour of it; as Monday from the moon, &c.

PLANTS, organised bodies, of which a full account has been given in the *Encycl.* under the title BOTANY, PLANT, SEXES, *&c.* The establishment of the sexual system in vegetables, and the acknowledged analogy between vegetable and animal bodies, has suggested a method of improving plants, as animals are confessedly improved, by what is called *crossing the breed*. This thought occurred first, we believe, to Andrew Knight, Esq; and in the Transactions of the Royal Society for 1799, we have an account of some very curious experiments made by him, with the view of ascertaining whether the improvement which he had conceived be actually practicable. Those were chiefly made on the garden pea, of which he had a kind growing in his yard; which having been long cultivated in the same soil, had ceased to be productive, and did not appear to recover the whole of its former vigour when removed to a soil of a somewhat different quality. On this his first experiment in 1787 was made. Having opened a dozen of its immature blossoms, he destroyed the male parts, taking great care not to injure the female ones; and a few days afterwards, when the blossoms appeared mature, he introduced the farina of a very large and luxuriant grey pea into one half of the blossoms, leaving the other half as they were. The pods of each grew equally well; but he soon perceived that of those into whose blossoms the farina had not been introduced, the seed remained nearly as they were before the blossom expanded, and in that state they withered. Those in the other pods attained maturity, but were not in any sensible degree different from those afforded by other plants of the same variety; owing, he imagines, to the external covering of the seed (as he had found in other plants) being furnished entirely by the female. In the succeeding spring, the difference, however, became extremely obvious; for the plants from them arose with excessive luxuriance, and the colour of their leaves and stems clearly indicated that they had all exchanged their whiteness for the colour of the male parent: the seeds produced in autumn were dark grey. By introducing the farina of another white variety (or in some instances by simple culture), he found this colour was easily discharged, and a numerous variety of new kinds produced; many of which were in size and every other respect much superior to the original white kind, and grew with excessive luxuriance, some of them attaining the height of more than twelve feet.

The dissimilarity he observed in the offspring, afforded by different kinds of farina in these experiments, pointed out to him an easy method of ascertaining whether superfœtation (the existence of which has been admitted among animals) could also take place in the vegetable world. For as the offspring of a white pea is always white, unless the farina of a coloured kind be introduced into the blossom, and as the colour of the grey one is always transferred to its offspring, though the female be white, it readily occurred to Mr Knight, that if the farina of both were mingled or applied at the same moment, the offspring of each could be easily distinguished.

His first experiment was not altogether successful; for the offspring of five pods (the whole which escaped the birds) received their colour from the coloured male. There was, however, a strong resemblance to the other male in the growth and character of more than one of the plants; and the seeds of several in the autumn very closely resembled it in every thing but colour. In this experiment he used the farina of a white pea, which possessed the remarkable property of shrivelling excessively when ripe; and in the second year he obtained white seeds from the grey ones above mentioned, perfectly similar to it. He is therefore strongly disposed to believe that the seeds were here of common parentage; but doth not conceive himself to be in possession of facts sufficient to enable him to speak with decision on this question. We have no right to form a decided opinion on this part of the subject, having paid to it very little attention; but at present we are inclined to think differently from the author. We admit, indeed, that if the female afford the first organized atom, and the male act only as a stimulus, it is by no means impossible that the explosion of two vesicles of farina, at the same moment (taken from different plants), may afford seeds of common parentage; but whether the female or the male affords the first organized atom, is the question which to us appears not yet decided.

Another ſpecies, however, of ſuperfœtation, in which one ſeed appears to have been the offspring of two males, has occurred to Mr Knight ſo often, as to remove, he ſays, all poſſibility of doubt as to its exiſtence. In 1797, the year after he had ſeen the reſult of the laſt mentioned experiment, having prepared a great many white bloſſoms, he introduced the farina of a white and that of a grey nearly at the ſame moment into each; and as in the laſt year the character of the coloured male had prevailed, he uſed its farina more ſparingly than that of the white one; and now almoſt every pod afforded plants of different colours. The majority, however, were white; but the characters of the two kinds were not ſufficiently diſtinct to allow him to judge with preciſion whether any of the ſeeds were produced of common parentage or not. In the year 1798 he was more fortunate; having prepared bloſſoms of the little early frame pea, he introduced its own farina, and immediately afterwards that of a very large and late grey kind, and ſowed the ſeeds thus obtained in the end of ſummer. Many of them retained the colour and character of the ſmall early pea, not in the ſlighteſt degree altered, and bloſſomed before they were eighteen inches high; whilſt others (taken from the ſame pods), whoſe colour was changed, grew to the height of more than four feet, and were killed by the froſt before any bloſſoms appeared.

It is evident, that in theſe inſtances ſuperfœtation took place; and it is equally evident that the ſeeds were not all of common parentage. Should ſubſequent experience evince, that a ſingle plant may be the offſpring of two males, the analogy between animal and vegetable nature may induce ſome curious conjectures relative to the proceſs of generation in the animal world.—It certainly may; but either we do not perfectly underſtand the author's meaning, or this experiment is not concluſive. There were here ſeeds of different colours produced by the farina of different males, operating on the ſame female plant; and there are well atteſted inſtances of twin children being born of different colours, in conſequence of the coition of different males, a negro and a white man, with the ſame woman. Had Mr Knight diſcovered, not that the ſame pod, but that the ſame individual *pea*, was the offſpring of two males, his diſcovery would indeed have led to ſome curious conjectures reſpecting animal generation. But to proceed with his experiments:

By introducing the farina of the largeſt and moſt luxuriant kinds into the bloſſoms of the moſt diminutive, and by reverſing this proceſs, he found that the powers of the male and female, in their effects on the offſpring, are exactly equal. The vigour of the growth, the ſize of the ſeeds produced, and the ſeaſon of maturity, were the ſame, though the one was a very early and the other a late variety. He had in this experiment a ſtriking inſtance of the ſtimulative effects of croſſing the breeds; for the ſmalleſt variety, whoſe height rarely exceeded two feet, was increaſed to ſix feet; whilſt the height of the large and luxuriant kind was very little diminiſhed. By this proceſs it is evident, that any number of new varieties may be obtained; and it is highly probable, that many of theſe will be found better calculated to correct the defects of different ſoils and ſituations than any we have at preſent.

The ſucceſs of Mr Knight's experiments on the pea induced him to make ſimilar experiments on wheat; but theſe did not anſwer his expectations. The varieties indeed which he obtained, eſcaped the blights of 1795 and 1796; but their qualities were not otherwiſe good, nor were they permanent. His experiments on the apple, the improvement of which was the firſt object of his attention, have, as far as he could judge from the cultivated appearance of trees which had not borne fruit when he wrote his memoir, been fully equal to his hopes. The plants which he obtained from his efforts to unite the good qualities of two kinds of apple, ſeem to poſſeſs the greateſt health and luxuriance of growth, as well as the moſt promiſing appearance in other reſpects. In ſome of theſe the character of the male appears to prevail; in others that of the female; and in others both appear blended, or neither is diſtinguiſhable. Theſe variations, which were often obſervable in the ſeeds taken from a ſingle apple, evidently ariſe from the want of permanence in the character of this fruit, when raiſed from ſeed. Many experiments of the ſame kind were tried on other plants; but it is ſufficient to ſay, that all tended to evince, that improved varieties of every fruit and of eſculent plants may be obtained by this proceſs, and that Nature intended that a ſexual intercourſe ſhould take place between neighbouring plants of the ſame ſpecies.

Plants, Nutrition of. This is a ſubject on which a variety of opinions has been entertained by modern chemiſts. Haſſenfratz conſiders carbon as the ſubſtance which nouriſhes vegetables. Ingenhouſz, in his work on the nutrition of plants, publiſhed in 1797, endeavours to prove, that if carbon has any influence in this reſpect, it can be only in the ſtate of carbonic acid, as that acid is abſorbed and decompoſed by vegetables; while the ligneous carbon, furniſhed by Nature, produces no effect on the [illegible] plants. Mr A. Young has endeavoured to [illegible] the ſame thing by experiments. Mr Rafn, a Daniſh chemiſt, deſirous of diſcovering [illegible] theſe contradictory opinions, [illegible] years, a ſeries of experiments, from [illegible] by the vegetation, ſize, and colour of [illegible] that carbon, either vegetable or [illegible] a decided influence in the nouriſhment of vegetables. What is new, and particularly worthy of remark in theſe reſearches, is, that, according to Mr Rafn, the carbonic acid produces exactly the ſame effect as charcoal of wood.

According to Mr Rafn, coal aſhes, on which the German and Engliſh farmers beſtow ſuch praiſe, deſtroy the plants if the ſoil contains an eighth part of that admixture. The leaves become faded, as if ſcorched, at the end of from fifteen to twenty days, and the plants themſelves die at the end of four or five weeks.

No ſeed germinates in oil. A ſingle grain of common ſalt, in 200 grains of water, is ſufficient to retard the vegetation of plants, and may even kill them if they are watered with that ſaline liquor.

Shavings of horn, next to infuſion animals, are the moſt favourable to vegetation: charcoal holds the third rank. For the truth of theſe opinions, ſee *Vegetable Substances* in this *Suppl.*

PLATINUM, or Platina (See Chemistry, *Suppl.* Part I. Chap. iii. Sect. 3.), is a metal, of which every chemiſt regrets the difficulty of making it malleable. Of the different proceſſes adopted to accompliſh this end, we have reaſon to believe that of Mr Richard Knight the moſt ſucceſsful; and, with the ſpirit

spirit of a true philosopher, he wishes to make that process as generally known, as possible. We shall give it in his own words:

"To a given quantity of crude platinum, I add (says he) 15 times its weight of nitro-muriatic acid (composed of equal parts of nitric and muriatic acids) in a tubulated glass retort, with a tubulated receiver adapted to it. It is then boiled, by means of an Argand's lamp, till the acid has assumed a deep saffron colour: it is then poured off; and if any platina remains undissolved, more acid is added, and it is again boiled until the whole is taken up. The liquor, being suffered to rest till quite clear, is again decanted: a solution of sal-ammoniac is then added, by little and little, till it no longer gives a cloudiness. By this means the platina is thrown down in the form of a lemon-coloured precipitate, which having subsided, the liquor is poured off, and the precipitate repeatedly washed with distilled water till it ceases to give an acid taste (too much water is injurious, the precipitate being in a certain degree soluble in that liquid); the water is then poured off, and the precipitate evaporated to dryness."

Thus far our author's method, as he candidly observes himself, differs not from that which has been followed by many others; but the remainder of the process is his own. "A strong, hollow, inverted cone of crucible earth being procured, with a corresponding stopper to fit it, made of the same materials, the point of the latter is cut off about three-fourths from the base. The platina, now in the state of a light yellow powder, is pressed tight into the cone, and a cover being fixed slightly on, it is placed in an air-furnace, and the fire raised gradually to a strong white heat. (The furnace used by Mr Knight is portable, with a chamber for the fire only eight inches in diameter.) In the mean time the conical stopper, fixed in a pair of iron tongs suitable for the purpose, is brought to a red, or to a bright white heat. The cover being then removed from the cone, the point of the heated stopper is introduced [illegible] of the furnace, and pressed at first gently on the platina, at this time in a state nearly as soft as dough, till it at length acquires a more solid consistence. It is then repeatedly struck with the stopper, as hard as the nature of the materials will admit, till it [illegible] to receive no farther impression. The cone is then removed from the furnace; and being struck lightly with a hammer, the platina falls out in a metallic button, from which state it may be drawn, by repeatedly heating and gently hammering, into a bar fit for flatting, drawing into wire, planishing, &c.

"Besides the comparative facility of this process, it has the farther advantage of rendering the platina much purer than when red-hot iron is obliged to be had recourse to; for platina, when of a white heat, has a strong affinity for iron, and, with whatever care it may have been previously separated from that metal, will be found to have taken up a portion of it, when it is employed of a red heat, to serve to unite the particles of the platina."

PLATONIC Bodies, see *Regular Bodies, Suppl.*

PLUVIAMETER, a machine for measuring the quantity of rain that falls, otherwise called Ombrometer; which see, *Encycl.*

POLLARDS, the name of a coarse kind of wheaten flour. When the flour of wheat is separated into three degrees of fineness, the third is the pollards. There is nothing between it and the bran.

PORCELAIN, a kind of earthen or stone ware, of the manufacture of which a full account is given in the *Encyclopædia* from Grosier and Reaumur. It may be proper, however, to add here, from Sir George Staunton, that one of the principal ingredients in the Chinese porcelain called *pe-tun-tse*, is a species of fine granite, or compound of quartz, feldspath, and mica, in which the quartz bears the largest proportion. "It appears (says Sir George) from several experiments, that *pe-tun-tse* is the same as the growan-stone of the Cornish miners. The micaceous part in some of this granite from both countries, often contains some particles of iron; in which case it will not answer the potter's purpose. This material can be calcined and ground much finer by the improved mills of England, than by the very imperfect machinery of the Chinese, and at a cheaper rate, than the prepared *pe tun-tse* of their own country, notwithstanding the cheapness of labour there. The *kao-lin*, or principal matter mixed with the *pe-tun-tse*, is the growan clay also of the Cornish miners. The *wha-she* of the Chinese is the English soap rock, and the *she-kao* is asserted to be gypsum.

"The manufacture of porcelain is said to be precarious from the want of some precise method of ascertaining and regulating the heat within the furnaces, in consequence of which, their whole contents are baked sometimes into one solid and useless mass." If this be so, Wedgewood's thermometer would be a present highly valuable to the Chinese potter, if that arrogant and conceited people would condescend to be taught by a native of Europe.

POSITION, Centre of, is a point of any body, or system of bodies, so selected, that we can estimate with propriety the situation and motion of the body or system by the situation and motion of this point. It is very plain that, in all our attempts to accurate discussion of mechanical questions, especially in the present extended sense of the word *mechanism*, such a selection is necessary. Even in common conversation, we frequently find it necessary to ascertain the distance of objects with a certain precision, and we then perceive that we must make some such selection. We conceive the distance to be mentioned, neither with respect to the nearest nor the remotest point of the object, but as a sort of average distance; and we conceive the point so ascertained to be somewhere about the middle of the object. The more we reflect on this, we find it the more necessary to attend to many circumstances which we had overlooked. Were it the question, to decide in what precise part of a country parish the church should be placed, we find that the geometrical middle is not always the most proper. We must consider the populousness of the different quarters of the parish, and select a point such, that the distances of the inhabitants on each side, in every direction, shall be as equally balanced as possible.

In mechanical discussions, the point by whose position and distance we estimate the position and distance of the whole, must be so selected, that its position and distance, estimated in any direction whatever, shall be the average of the positions and distances of every particle of the assemblage, estimated in that direction.

This will be the case, if the point be so selected that, when a plane is made to pass through it *in any direction*

Position. *tion whatever*, and perpendiculars are drawn to this plane from every particle in the body or system, the sum of all the perpendiculars on one side of this plane is equal to the sum of all the perpendiculars on the other side. If there be such a point in a body, the position and motion of this point is the average of the positions and motions of all the particles.

Plate XL. For if P (fig. 1.) be a point so situated, and if QR be a plane (perpendicular to the paper) at any distance from it, the distance P*p* of the point from this plane is the average of the distances of all the particles from it. For let the plane APB be passed through P, parallel to QR. The distance CS of any particle C from the plane QR is equal to DS−DC, or to P*p*—DC. And the distance GT of any particle G lying on the other side of APB, is equal to HT+GH, or to P*p*+GH. Let *n* be the number of particles on that side of AB which is nearest to QR, and let *o* be the number of those on the remote side of AB, and let *m* be the number of particles in the whole body, and therefore equal to $n+o$. It is evident that the sum of the distances of all the particles, such as C, is *n* times P*p*, after deducting all the distances, such as DC. Also the sum of all the distances of the particles, such as G, is *o* times P*p*, together with the sum of all the distances, such as GH. Therefore the sum of both sets is $\overline{n+o} \times \mathrm{P}p +$ sum of GH — sum of DC, or $m \times \mathrm{P}p +$ sum of GH — sum of DC. But the sum of GH, wanting the sum of DC, is nothing, by the supposed property of the point P. Therefore $m \times \mathrm{P}p$ is the sum of all the distances, and P*p* is the *m*th part of this sum, or the average distance.

Now suppose that the body has changed both its place and its position with respect to the plane QR, and that P (fig. 2.) is still the same point of the body, and π P 3 a plane parallel to QR. Make $p\,\pi$ equal to *p* P of fig. 1. It is plain that P*p* is still the average distance, and that $m \times \mathrm{P}p$ is the sum of all the present distances of the particles from QR, and that $m \times \pi p$ is the sum of all the former distances. Therefore $m \times \mathrm{P}\pi$ is the sum of all the changes of distance, or the whole quantity of motion estimated in the direction π P. Pπ is the *m*th part of this sum, and is therefore the average motion in this direction. The point P has therefore been properly selected; and its position, and distance, and motion, in respect of any plane, is a proper representation of the situation and motion of the whole.

It follows from the preceding discussion, that if any particle C (fig. 1.) moves from C to N, in the line CS, the centre of the whole will be transferred from P to Q, so that PQ is the *m*th part of CN; for the sum of all the distances has been diminished by the quantity CN, and therefore the average distance must be diminished by the *m*th part of CN, or PQ is $= \frac{\mathrm{CN}}{m}$.

But it may be doubted whether there is in every body a point, and but one point, such that if a plane pass through it, *in any direction whatever*, the sum of all the distances of the particles on one side of this plane is equal to the sum of all the distances on the other.

It is easy to shew that such a point may be found, with respect to a plane parallel to QR. For if the sum of all the distances DC exceed the sum of all the distances GH, we have only to pass the plane AB a little nearer to QR, but still parallel to it. This will diminish the sum of the lines DC, and increase the sum of the lines GH. We may do this till the sums are equal.

In like manner we can do this with respect to a plane LM (also perpendicular to the paper), perpendicular to the plane AB. The point wanted is somewhere in the plane AB, and somewhere in the plane LM. Therefore it is somewhere in the line in which these two planes intersect each other. This line passes through the point P of the paper where the two lines AB and LM cut each other. These two lines represent planes, but are, in fact, only the intersection of those planes with the plane of the paper. Part of the body must be conceived as being above the paper, and part of it behind or below the paper. The plane of the paper therefore divides the body into two parts. It may be so situated, therefore, that the sum of all the distances from it to the particles lying above it shall be equal to the sum of all the distances of those which are below it. Therefore the situation of the point P is now determined, namely, at the common intersection of three planes perpendicular to each other. It is evident that this point alone can have the condition required in respect of these three planes.

But it still remains to be determined whether the same condition will hold true for the point thus found, in respect to *any other* plane passing through it; that is, whether the sum of all the perpendiculars on one side of *this fourth* plane is equal to the sum of all the perpendiculars on the other side. Therefore

Let AGHB (fig. 3.), AXYB, and CDFE, be three planes intersecting each other perpendicularly in the point C; and let CIKL be any other plane, intersecting the first in the line CI, and the second in the line CL. Let P be any particle of matter in the body or system. Draw PM, PO, PR, perpendicular to the first three planes respectively, and let PR, when produced, meet the oblique plane in V; draw MN, ON, perpendicular to CE. They will meet in one point N. Then PMNO is a rectangular parallelogram. Also draw NQ perpendicular to CE, and therefore parallel to AB, and meeting CI in S. Draw SV; also draw ST perpendicular to VP. It is evident that SV is parallel to CL, and that STRQ and STPM are rectangles.

All the perpendiculars, such as PR, on one side of the plane CDFE, being equal to all those on the other side, they may be considered as compensating each other; the one being considered as positive or additive quantities, the other are negative or subtractive. There is no difference between their sums, and the sum of both sets may be called o or nothing. The same must be affirmed of all the perpendiculars PM, and of all the perpendiculars PO.

Every line, such as RT, or its equal QS, is in a certain invariable ratio to its corresponding QC, or its equal PO. Therefore the positive lines RT are compensated by the negative, and the sum total is nothing.

Every line, such as TV, is in a certain invariable ratio to its corresponding ST, or its equal PM, and therefore their sum total is nothing.

Therefore the sum of all the lines PV is nothing; but each is in an invariable ratio to a corresponding perpendicular from P on the oblique plane CIKL. Therefore the sum of all the positive perpendiculars on this plane is equal to the sum of all the negative perpendiculars, and the proposition is demonstrated, viz. that

in

in every body, or system of bodies, there is a point such. that if a plane be passed through it *in any direction whatever*, the sum of all the perpendiculars on one side of the plane is equal to the sum of all the perpendiculars on the other side.

The point P, thus selected, may, with great propriety, be called the CENTRE OF POSITION of the body or system.

If A and B (fig. 4.) be the centres of position of two bodies, whose quantities of matter (or numbers of equal particles) are a and b, the centre C lies in the straight line joining A and B, and $AC : CB = b : a$, or its distance from the centres of each are inversely as their quantities of matter. For let $\alpha C \beta$ be any plane passing through C. Draw $A\alpha$, $B\beta$, perpendicular to this plane. Then we have $a \times A\alpha = b \times B\beta$, and $A\alpha : B\beta = b : a$, and, by similarity of triangles, $CA : CB = b : a$.

If a third body D, whose quantity of matter is d, be added, the common centre of position E of the three bodies is in the straight line DC, joining the centre D of the third body with the centre C of the other two, and $DE : EC = a + b : d$. For, passing the plane $\delta E \kappa$ through E, and drawing the perpendiculars $D\delta$, $C\kappa$, the sum of the perpendiculars from D is $d \times D\delta$; and the sum of the perpendiculars from A and B is $\overline{a+b} \times C\kappa$, and we have $d \times D\delta = \overline{a+b} \times C\kappa$; and therefore $DE : EC = a + b : d$.

In like manner, if a fourth body be added, the common centre is in the line joining the fourth with the centre of the other three, and its distance from this centre and from the fourth is inversely as the quantities of matter; and so on for any number of bodies.

If all the particles of any system be moving uniformly, in straight lines, in any directions, and with any velocities whatever, the centre of the system is either moving uniformly in a straight line, or [illegible].

For, let m be the number of particles in the system. Suppose any particle to move uniformly in any direction. It is evident from the reasoning in a former paragraph, that the motion of the common centre is the mth part of this motion, and is in the same direction. The same must be said of every particle. Therefore the motion of the centre is the motion which is compounded of the mth part of the motion of each particle. And because each of these was supposed to be uniform and rectilineal, the motion compounded of them all is also uniform and rectilineal; or it may happen that they will so compensate each other that there will be no diagonal, and the common centre will remain at rest.

Cor. 1. If the centres of any number of bodies move uniformly in straight lines, whatever may have been the motions of each particle of each body, by rotation or otherwise, the motion of the common centre will be uniform and rectilineal.

Cor. 2. The quantity of motion of such a system is the sum of the quantities of motion of each body, reduced to the direction of the centre's motion. And it is had by multiplying the quantity of matter in the system by the velocity of the centre.

The velocity of the centre is had by reducing the motion of each particle to the direction of the centre's motion, and then dividing the sum of those reduced motions by the quantity of matter in the system.

By the selection of this point, we render the investigation of the motions and actions of bodies incomparably more simple and easy, freeing our discussions from numberless intricate complications of motion, which would frequently make our progress almost impossible.

POSITION, in arithmetic, called also *False Position*, or *Supposition*, or *Rule of False*, is a rule so called, because it consists in calculating by false numbers supposed or taken at random, according to the process described in any question or problem proposed, as if they were the true numbers, and then from the results, compared with that given in the question, the true numbers are found.

Thus, take or assume any number at pleasure for the number sought, and proceed with it as if it were the true number, that is, perform the same operations with it as, in the question, are described to be performed with the number required: then if the result of those operations be the same with that mentioned or given in the question, the supposed number is the same as the true one that was required; but if it be not, make this proportion, *viz.* as your result is to that in the question, so is your supposed false number to the true one required.

Example. What number is that, to which if we add $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, and $\frac{1}{6}$ of itself, the sum will be 240?

Suppose 99

$$\begin{array}{rl} 49.5 & = \frac{1}{2} \\ 33. & = \frac{1}{3} \\ 24.75 & = \frac{1}{4} \\ 16.5 & = \frac{1}{6} \\ \hline 222.75 & = \text{result} \end{array}$$

Then, as $222.75 : 240 :: 99 : 106.6$ = Answer.

$$\begin{array}{rl} 53.\dot{3} & = \frac{1}{2} \\ 35.\dot{5} & = \frac{1}{3} \\ 26.\dot{6} & = \frac{1}{4} \\ 17.\dot{7} & = \frac{1}{6} \\ \hline 240. & = \text{proof.} \end{array}$$

This is *single* position.

Sometimes it is necessary to make two different suppositions or assumptions, when the same operations must be performed with each as in the single rule. If neither of the supposed numbers solve the question, find the differences between the results and the given number; multiply each of these differences into the other's position; and if the errors in both suppositions be of the same kind, *i. e.* if both suppositions be either less or greater than the given number, divide the differences of the products by the differences of the errors. If the errors be not of the same kind, *i. e.* if the one be greater and the other less than the given number, divide the sum of the products by the sum of the errors. The quotient, in either case, will be the answer.

Example. Three partners, A, B, and C, bought a sugar-work which cost them L. 2000; of which A paid a certain sum unknown; B paid as much as A, and L. 50 over; C paid as much as them both, and L. 75 over: What sum did each pay?

(1.) Suppose A paid L. 500

$$\begin{array}{rr} \text{B} \text{ ---- } & 550 \\ \text{C} \text{ ---- } & 1075 \\ \hline & 2125 \\ & 2000 \\ \hline & 125 = \text{error of excess.} \end{array}$$

(2.) Sup-

(2.) Suppose A paid L. 400
B —— 450
125 = excess. C —— 875

400 = 2d position. 1725
2000
50000
275 = error of defect.
500 = 1st position.

1st error, 125 137500
2d —— 275 50000

400)187500

Answers. { 468.75 = sum paid by A. / 518.75 = —— B. / 1012.5 = —— C. }

2000... = proof.

This is called double position.

POTTERY is an art of very considerable importance; and in addition to what has been said on it in the *Encyclopædia*, the following reflections, by that eminent chemist Vauquelin, will probably be acceptable to many of our readers.

Four things (says he) may occasion difference in the qualities of earthen-ware: *1st*, The nature or composition of the matter; *2d*, The mode of preparation; *3d*, The dimensions given to the vessels; *4th*, The baking to which they are subjected. By composition of the matter, the author understands the nature and proportions of the elements of which it is formed. These elements, in the greater part of earthen-ware, either valuable or common, are silex, argil, lime, and sometimes a little oxyd of iron. Hence it is evident that it is not so much by the diversity of the elements that good earthen-ware differs from bad, as by the proportion in which they are united. Silex or quartz makes always two-thirds at least of earthen-ware; argil or pure clay, from a fifth to a third; lime, from 5 to 20 parts in the hundred; and iron, from 0 to 12 or 15 parts in the hundred. Silex gives hardness, infusibility, and unalterability; argil makes the paste pliable, and renders it fit to be kneaded, moulded, and turned at pleasure. It possesses at the same time the property of being partially fused by the heat which unites its parts with those of the silex; but it must not be too abundant, as it would render the earthen-ware too fusible and too brittle to be used over the fire.

Hitherto it has not been proved by experience that lime is necessary in the composition of pottery: and if traces of it are constantly found in that substance, it is because it is always mixed with the other earths, from which the washings and other manipulations have not been able to separate it. When this earth, however, does not exceed five or six parts in a hundred, it appears that it is not hurtful to the quality of the pottery; but if more abundant, it renders it too fusible.

The oxyd of iron, besides the inconvenience of communicating a red or brown colour, according to the degree of baking, to the vessels in which it forms a part, has the property of rendering them fusible, and even in a greater degree than lime.

As some kinds of pottery are destined to melt very penetrating substances, such as salts, metallic oxyds, glass, &c. they require a fine kind of paste, which is obtained only by reducing the earths employed to very minute particles. Others destined for melting metals, and substances not very penetrating, and which must be able to support, without breaking, a sudden transition from great heat to great cold, require for their fabrication a mixture of calcined argil with raw argil. By these means you obtain pottery, the coarse paste of which resembles *breche*, or small-grained pudding-stone, and which can endure sudden changes of temperature.

The baking of pottery is also an object of great importance. The heat must be capable of expelling humidity, and agglutinating the parts which enter into the composition of the paste, but not strong enough to produce fusion; which, if too far advanced, gives to pottery a homogenuousness that renders it brittle. The same effect takes place in regard to the fine pottery, because the very minute division given to the earths reduces them nearly to the same state as if this matter had been fused. This is the reason why porcelain strongly baked is more or less brittle, and cannot easily endure alternations of temperature. Hence coarse porcelain, in the composition of which a certain quantity of calcined argil is employed, porcelain retorts, crucibles, tubes, and common pottery, the paste of which is coarse, are much less [illegible] formed of the same substances [illegible].

The general and [illegible] different parts of which of earthen-ware [illegible] their [illegible] to stand the fire.

In some cases the glazing or covering [illegible] when too thick, and of a nature different from [illegible] liable to break. [illegible] in [illegible] it is always [illegible] [illegible] the principles; 2d. To [illegible] the paste, by grinding [illegible] [illegible] which it is intend[illegible] [illegible] de[illegible] [illegible] fused [illegible] [illegible] of [illegible] possible to that of [illegible] may be more intimately [illegible]

C. Vauquelin being persuaded that the quality of good pottery depends chiefly on using proper proportions of the earthy matters, thought it might be of importance to those engaged in this branch of manufacture, to make known the analysis of different natural clays employed for this purpose, and of pottery produced by some of them, in order that, when a new earth is discovered, it may be known by a simple analysis whether it will be proper for the same object, and to what kind of pottery already known it bears the greatest resemblance.

	Hessian Crucibles.	Argil of Dieux.	Porcelain Capsules.	Wedgewood's Pyrometers.
Silex	69	43·5	61	64·2
Argil	21·5	33·2	28	25
Lime	1	3·5	6	6
Oxyd of iron	8	1	0·5	0·2
Water	. . .	18	. . .	6·2

Raw

Raw kaolin 100 parts.—Silex 74, argil 16·5, lime 2, water 7. A hundred parts of this earth gave eight of alum, after being treated with the sulphuric acid.

Washed kaolin 100 parts.—Silex 55, argil 27, lime 2, iron 0·5, water 14. This kaolin, treated with the sulphuric acid, gave about 45 or 50 *per cent.* of alum.

Petuntzé.—Silex 74, argil 14·5, lime 5·5, loss 6. A hundred parts of this substance, treated with the sulphuric acid, gave seven or eight parts of alum. But this quantity does not equal the loss sustained.

Porcelain of retorts.—Silex 64, argil 28·8, lime 4·55, iron 0·50, loss 2·77. Treated with the sulphuric acid, this porcelain gave no alum.

There is a kind of earthen vessels, called *Alcarrazes*, used in Spain for cooling the water intended to be drunk. These vessels consist of 60 parts of calcareous earth, mixed with alumina and a little oxyd of iron, and 36½ of siliceous earth, also mixed with alumina and the same oxyd. The quantity of iron may be estimated at almost one hundredth part of the whole. This earth is first kneaded into a tough paste, being for that purpose previously diluted with water; formed into a cake of about six inches in thickness, and left in that state till it begin to crack. It is then kneaded with the feet, the workman gradually adding to it a quantity of sea-salt, in the proportion of [illegible] pounds to a hundred and fifty; after which it is applied to the lath, and baked in any kind of furnace used by potters. The alcarrazes, however, are only about half as much baked as the better kinds of common earthen ware; and being exceedingly porous, water comes through their whole sides. Hence the air, which comes in contact with it, by making it evaporate, carries off the caloric contained in the water [illegible] rendered remarkably cool.

POULES, or Foulahs, [illegible] nations which inhabit the banks [illegible] They possess an extent of [illegible] river, and extend [illegible] ders with the interior of the country [illegible] so black as the other negroes, but [illegible] much inclining to red. [illegible] their children who are sent to Senegal [illegible] for some years, become much blacker [illegible] are very handsome, and the whites of Senegal [illegible] take care to procure some of them. But they are of a bad disposition, and utterly incapable of attachment. When a man has a mistress of this nation, he must watch her conduct very narrowly, and even chastise her, that she may not be guilty of infidelity to him whom she honours with her favours. The dread of the bastinado will, in such case, effect what attention and complaisance can never bring about.

Although the Poules inhabit one of the finest spots in Africa, they are nevertheless a wretched people; they are base, cruel, thievish, and fanatic in the extreme. They are commanded by a chief of their religion, which is a contemptible mixture of Mahometanism and idolatry. This chief is called the *Almamy;* he is always chosen from among the Tampsirs, who are twelve in number. The Tampsirs are the interpreters of the law, and are the most learned, or rather the most fanatical among them. The Almamy has the power of life and death over his subjects; yet he may be deposed by an assembly of Tampsirs: it is therefore his interest to keep on good terms with them. The payment of customs is made to the Almamy, and is afterwards distributed among the Tampsirs; and although a part belongs to the former, he nevertheless requires a separate present for himself.

Printing.

PRINTING. (See that article, *Encycl.* and TYPOGRAPHY in this *Supplement.*) We shall here only describe a *Printing-Press*, for the invention of which a patent was granted, in 1790, to Mr William Nicholson of New North-street, Red Lion Square, London. This machine, with some slight varieties, is adapted for printing on *paper, linen, cotton, woollen*, and other articles, in a more neat, cheap, and accurate method, the author thinks, than the printing presses now in use.

The invention consists in three particulars, *1st*, The manner of preparing and placing the types, engravings, or carvings, from which the impression is to be made; *2dly*, In applying the ink or colouring matter to types or engravings; and, *3dly*, In taking off the impression.

1st, Mr Nicholson makes his moulds, punches, and matrices, for casting letters, in the same manner, and with the same materials, as other letter-founders do, excepting that, instead of leaving a space in the mould for the stem of one letter only, he leaves spaces for two, three, or more letters, to be cast at one pouring of the metal; and at the lower extremity of each of those spaces (which communicate by a common groove at top) he places a matrix, or piece of copper, with the letter punched upon its face in the usual way. And moreover, he brings the stem of his letters to a due form and finish, not only by rubbing it upon a stone, and scraping it when arranged in the finishing-stick, but likewise by scraping it, on one or more sides, in a finishing-stick whose hollowed part is less deep at the inner than the outer side. He calls that side of the groove which is nearest the face of the disposed letter, the outer side; and the purpose accomplished by this method of scraping is, that of rendering the tail of the letter gradually smaller the more remote it is, or farther from the face. Such letters may be firmly imposed upon a cylindrical surface, in the same manner as common letters are imposed upon a flat stone.

2dly, He applies the ink or colouring matter to the types, forms, or plates, by causing the surface of a cylinder, smeared or wetted with the colouring matter, to roll over the surfaces of the said forms or plates, or by causing the forms or plates apply themselves successively to the surface of the cylinder. The surface of this colouring cylinder is covered with leather, or with woollen, linen, or cotton-cloth. When the colour to be used is thin, as in calico-printing, and in almost every case, the covering is supported by a firm elastic stuffing, consisting of hair, or wool, or woollen cloth wrapped one or more folds round the cylinder. When the covering consists of woollen cloth, the stuffing must be defended by leather, or oilskin, to prevent its imbibing too much colour, and by that means losing its elasticity. It is absolutely necessary that the colouring matter be evenly distributed over the surface of the cylinder; and for this purpose, when the colour is thick and stiff, as in letter-press printing, he applies two, three, or more small cylinders, called distributing-rollers, longitudinally against the colouring cylinders, so that they may be turned by the motion of the latter; and the effect of this application is, that every lump or mass of colour which may be redundant, or irregularly placed upon the face of the colouring cylinder, will be pressed, spread,

Printing.

spread, and partly taken up, and carried by the small rollers to the other parts of the colouring cylinder; so that this last will very speedily acquire and preserve an even face of colour. But if the colouring matter be thinner, he does not apply more than one or two of these distributing rollers; and, if it be very thin, he applies an even blunt edge of metal, or wood, or a straight brush, or both of these last, against the colouring cylinder, for the purpose of rendering its colour uniform. When he applies colour to an engraved plate, or cylinder, or through the interstices of a perforated pattern, as in the manufacturing of some kinds of paper-hangings, he uses a cylinder entirely covered with hair or bristles in the manner of a brush.

3dly, He performs all his impressions, even in letter-press printing, by the action of a cylinder or cylindrical surface. The construction of this machine, and the manner of using it, will be intelligible to every reader, who shall attentively consider Plate XL; where fig. 1. represents a printing press, more especially applicable to the printing of books. A and E are two cylinders, running or turning in a strong frame of wood, or metal, or both. The cylinder A is faced with woollen cloth, and is capable of being pressed with more or less force upon HI, by means of the lever M. HI is a long table, which is capable of moving endwise, backwards and forwards, upon the rollers E and K. The roller A acts upon this table by means of a cog-wheel, or by straps, so as to draw it backwards and forwards by the motion of its handle L. The table is kept in the same line by grooves on its sides, which contain the cylinder A. D is a chase, containing letter set up and imposed. B is a box, containing a colouring-roller, with its distributing rollers CC; it is supported by the arm N. O is a cylinder faced with leather, and lying across an ink-block; this cylinder is fixed by the middle to a bended lever moveable on the joint Q.

The action. When D, or the letter, is drawn beneath the cylinder B, it receives ink; and when it has passed into the position R, a workman places or turns down a tympan with paper upon it (this tympan differs in no respect from the usual one, except that its hinge opens sidewise); it then proceeds to pass under the cylinder A, which presses it successively through its whole surface. On the other side, at S, the workman takes off the paper, and leaves the tympan up. This motion causes the cylinder B to revolve continually, and consequently renders its inked surface very uniform, by the action of its distributing-rollers CC; and, when the table has passed to its extreme distance in the direction now spoken of, the arm G touches the lever P, and raises the cylinder O off the ink-block, by which means it dabs against one of the distributing-rollers, and gives it a small quantity of ink. The returning motion of the table carries the letter again under the roller B, which again inks it, and the process of printing another sheet goes on as before.

Fig. 2. is another printing-press. In this, B is the inking-roller; A is a cylinder, having the letter imposed upon its surface; and E is a cylinder, having its uniform surface covered with woollen cloth: these three cylinders are connected, either by cogs or straps at the edges of each. The machine is uniformly turned in one direction by the handle L. The workman applies a sheet of paper to the surface of E, where it is retained, either by points in the usual manner, or by the apparatus to be described in treating of fig. 4. The paper passes between E and A, and receives an impression; after which the workman takes it off, and applies another sheet; and in the mean time the letter on the surface of A passes round against the surface of B, and receives ink during the rotation of B. The distributing-rollers CC do their office as in the machine fig. 1.; and once in every revolution the tail F, affixed to B, raises the inking-piece G, so as to cause it to touch one of the distributing-rollers, and supply it with ink. In this way therefore the repeated printing of sheet after sheet goes on.

Fig. 3. is a printing press, more particularly adapted to print cottons, silks, paper hangings, or other articles which run of a considerable length. A is a cylinder covered with woollen cloth, or other soft substance. The web or piece of cotton, or other goods, is passed round this cylinder, from the carrying-roller F to the receiving-rollers GH; which are connected by a piece of linen, woollen, or hair-cloth, in the manner of a jack-towel sewed round them; the rotation of this towel carries away the printed stuff or goods, and deposits them at I. KL is a moveable box, containing three rollers, which move against each other in rotation. The lowest roller C revolves in a mass of colour, contained in a trough or vessel in the bottom part of the box KL; the [illegible] of this colour is represented by the line [illegible]. The [illegible] roller B is stuffed and covered as described in [illegible] 2. The pressure of B against C prevents the cylinder B from receiving too much colour. D is a cut or carved cylinder, which receives colour, during the rotation, from the roller B, and imprints it upon the web as it [illegible] round the cylinder A. In this way the construction [illegible] [illegible] is sufficiently obvious. [illegible] cylinders ADB and G [illegible] wheels, straps, or other well-known [illegible]; so that the handle [illegible] depending on [illegible]. The pressure [illegible] adjustment of [illegible] A is governed by [illegible] KL. When it is required [illegible] colour upon a piece, Mr [illegible] it to pass two or more times through the machine; or, in those cases where the materials are liable to change their dimensions, he applies, at one and the same time, two or more such boxes as KL, with their respective cylinders, so that the pattern cylinder of each may make its impression upon the web or material to be printed on.

Fig. 4. is a printing-press, chiefly of use for books and papers. 1, 2, 3, 4, represents a long table, with ledges on each side; so that the two cylinders A and B can run backwards and forwards without any side shake. In one of these ledges is placed a strip or plate of metal cut into teeth, which lock into correspondent teeth in each cylinder; by which means the two cylinders roll along, without the possibility of changing the relative positions of their surfaces at any determinate part of the table. This may also be effected by straps, and may indeed be accomplished, with tolerable accuracy, by the mere rolling of the cylinders on the smooth or flat ledges without any provision. A is the printing-cylinder, covered with woollen cloth, and B is the inking-cylinder, with its distributing rollers. The tab[le]

may be divided into four compartments, marked with a thicker bounding line than the rest, and numbered 1, 2, 3, 4. At 1 is placed a sheet of paper; at 2 is the form or chase, containing letter set and imposed; at 3 is an apparatus for receiving the printed sheet; and 4 is employed in no other use than as a place of standing for the carriage E, after it has passed through one operation, and when it takes ink at F. Its action is as follows: the carriage is thrust forward by the workman, and as the roller A passes over the space numbered 1, it takes up the sheet of paper previously laid there, while the roller B runs over the form and inks the letter. The sheet of paper, being wrapped round the cylinder A, is pressed against the form as that cylinder proceeds, and consequently it receives an impression. When A arrives at the space numbered 3, it lets go the sheet of paper, while the prominent part of the carriage G strikes the lever P, and raises the inking-piece, which applies itself against one of the distributing-rollers. In this manner therefore the cylinder A returns empty, and the cylinder B inked, and in the mean time the workman places another sheet of paper ready in the space numbered 1. Thus it is that the operation proceeds in the printing of one sheet after another.

The preceding description is not incumbered with an account of the apparatus by which the paper is taken up and laid down. This may be done in several ways: Fig. 9. and 10. represent one of the methods. DE is a lever, moving on the centre pin C, and having its end D pressed upwards by the action of the spring G. The shoulder which contains the pin C is fixed in another piece F, which is inserted in a groove in the surface of the cylinder A (fig. 9.), so that it is capable of moving in and out [illegible] to the axis of that cylinder. [illegible] cylinder proceeds, it meets a pin in the table, which [illegible] (fig. 9.) acting on the inclined plane at the other end of the lever, throws the whole inwards [illegible] in fig. 10.; in which case the [illegible] wards, and applies itself against the [illegible].

In fig. 11. is a representation of [illegible]; the dotted square represents a sheet [illegible] the four small shaded squares denote [illegible] with pins standing beside them. When the lever DE (fig. 10.) shoots forward, it is situated in one of these holes, and advances under the edge of the paper, which consequently it presses and retains against the cylinder with its extremity D. Nothing more remains to be said respecting the taking up, but that the cylinder is provided with two pair of these clasps or levers, which are so fixed as to correspond with the four holes represented in fig. 11. It will be easy to understand how the paper is deposited in the compartment n° 3. (fig. 4.) A pin P (fig. 10.) rising out of the platform or table, acts against a pin E, projecting sidewise out of the lever, and must of course draw the slider and its lever to the original position; the paper consequently will be let go, and its disengagement is rendered certain by an apparatus fixed in the compartment numbered 3. (fig. 4.) of exactly the same kind as that upon the cylinder, and which, by the action of a pin duly placed in the surface of the cylinder A, takes the paper from the cylinder in precisely the same manner as that cylinder originally took it up in the compartment numbered 1 (fig. 4.)

Figs. 5, 6, and 7, represent a simpler apparatus for accomplishing the same purpose. If A a B b (fig 7.) be supposed to represent a thick plate of metal of a circular form, with two pins, A and B, proceeding sidewise or perpendicularly out of its plane, and diametrically opposite to each other, and G another pin proceeding in the direction of that plane, then it is obvious that any force applied to the pin A, so as to press it into the position *a* (by turning the plate on its axis or centre X), will at the same time cause the pin G to acquire the position *g*; and, on the other hand, when B is at *b*, or the dotted representation of the side pin, if any pressure be applied to restore its original position at B, the pin *g* will return back to G. Now the figures 5 and 6 exhibit an apparatus of this kind, applied to the cylinder A; and that cylinder, by rolling over the pins P and *p*, properly fixed in the table to re act upon the apparatus, will cause its prominent part G either to apply to the cylinder and clasp the paper, or to rise up and let it go. The compartment numbered 3 (fig. 4.) must of course have an apparatus of the same kind to be acted upon by pins from A, in order that it may take the paper from that cylinder.

There is one other circumstance belonging to this machine which remains to be explained. When the carriage E (fig. 4.) goes out in the direction of the numbers 1, 2, 3, 4, both rollers, A and B, press the form of letter in their passage; but in their return back again the roller A, having no paper upon it, would itself become soiled, by taking a faint impression from the letter, if it were not prevented from touching it; the manner of effecting this may be understood from fig. 12. The apparatus there represented is fixed upon the outside of the carriage E, near the lower corner, in the vicinity of the roller A; the whole of this projects sidewise beyond the ledge of the table, except the small truck or wheel B. The irregularly triangular piece, which is shaded by the stroke of the pen, carries this wheel, and also a catch moveable on the axis or pin E. The whole piece is moveable on the pin A, which connects it to the carriage. CD, or the part which is shaded by dotting, is a detent, which serves to hold the piece down in a certain position. It may be observed, that both the detent and the triangular piece are furnished each with a claw, which holds in one direction, but trips or yields in the other, like the jacks of a harpsichord, or resembling certain pieces used in clock and watch making, as is clearly represented in the figure. These claws overhang the side of the table, and their effect is as follows: There is a pin C (fig. 4.) between the compartments of the table numbered 2 and 3, but which is marked F in fig. 12. where GH represents the table. In the outward run of the carriage these claws strike that pin, but with no other effect than that they yield for an instant, and as instantly resume their original position by the action of their respective slender back-springs. When the carriage returns, the claw of the detent indeed strikes the pin, but with as little effect as before, because its derangement is instantly removed by the action of the back spring of the detent itself; but, when the claw of the triangular piece takes the pin, the whole piece is made to revolve on its axis or pin A, the wheel B is forced down, so as to lift that end of the carriage, and the detent, catching on the piece at C, prevents the former position from being recovered.

covered. The consequence of this is, that the carriage runs upon the truck B (and its correspondent truck on the opposite side) instead of the cylinder A, which is too much raised to take the letter, and soil itself; but as soon as the end of the carriage has passed clear of the letter, another pin R (fig. 4.) takes the claw of the detent, and draws it off the triangular piece; at which instant the cylinder A subsides to its usual place, and performs its functions as before. This last pin R does not affect the claw of the triangular piece, because it is placed too low; and the claw of the detent is made the longest, on purpose that it may strike this pin.

Fig. 8. represents an instrument for printing floor-cloths, paper-hangings, and the like, with stiff paint and a brush. D is a copper or metallic cylinder fixed in a frame A, like a garden roller; its carved part is thin, and is cut through in various places, according to the desired pattern. A strong axis passes through the cylinder, and its extremities are firmly attached to the frame A. To this axis is fixed a vessel or box of the same kind, and answering the same purpose as the box KL in fig. 3. It carries a cylinder P, which revolves in the colour; another cylinder E, which revolves in contact with P; and a third cylinder B, whose exterior surface is covered with hair, after the manner of a brush, and revolves in contact with E. This cylinder B is adjusted by its axis, in such a manner that its brush-part sweeps in the perforated parts of the metallic cylinder D. The circle C represents a cog-wheel, fixed concentric to the cylinder D, and revolving with it; this wheel takes another wheel concentric to, and fixed to, B; hence the action is as follows: When the metallic cylinder is wheeled or rolled along any surface, its cog-wheel C drives the brush B in the contrary direction; and this brush-cylinder, being connected by cogs or otherwise with E and P, causes those also to revolve and supply it with colour. As the successive openings of the cylinder D, therefore, come in contact with the ground, the several parts of the brush will traverse the uncovered part of that ground, and paint the pattern upon it. The wheel G, being kept lightly on the ground, serves to determine the line of contact, that it shall be the part opposite to B, and no other.

PRINTS (see *Encycl.*) are valuable on many accounts; but they are liable to be soiled by smoke, vapour, and the excrements of insects. Different methods have, of course, been practised to clean them. Some have proposed simple washing with clear water, or a ley made of the ashes of reeds, and then exposing the prints to the dew. Others have cleaned prints with *aqua fortis* (sulphuric acid); but both these methods are attended with a degree of risk at least equal to their advantages. The following method of cleaning prints is recommended in the second volume of Nicholson's Journal of Natural Philosophy, &c. as at once safe and efficacious:

"Provide a certain quantity of the common muriatic acid, for example three ounces, in a glass bottle, with a ground-stopper, of such a capacity that it may be only half full. Half an ounce of minium must then be added; immediately after which the stopper is to be put in, and the bottle set in a cold and dark place. The heat, which soon becomes perceptible, shews the beginning of the new combination. The minium abandons the greatest part of its oxygen with which the fluid remains impregnated, at the same time that it acquires a fine golden yellow, and emits the detestable smell of oxygenated muriatic acid. It contains a small portion of muriat of lead; but this is not at all noxious in the subsequent process. It is also necessary to be observed, that the bottle must be strong, and the stopper not too firmly fixed, otherwise the active elastic vapour might burst it. The method of using this prepared acid is as follows:

"Provide a sufficiently large plate of glass, upon which one or more prints may be separately spread out. Near the edges let there be raised a border of soft white wax half an inch high, adhering well to the glass and flat at top. In this kind of trough the print is to be placed in a bath of fresh urine, or water containing a small quantity of ox-gall, and kept in this situation for three or four hours. The fluid is then to be decanted off, and pure warm water poured on, which must be changed every three or four hours until it passes limpid and clear. The impurities are sometimes of a resinous nature, and resist the action of pure water. When this is the case, the washed print must be left to dry, and alcohol is then to be poured on and left for a time. After the print is thus cleaned, and all the moisture drained off, the muriatic acid prepared with minium is to be poured on in sufficient quantity to cover the print; immediately after which another plate of glass is to be laid in contact with the rim of wax, in order to prevent the inconvenient exhalation of the oxygenated acid. In this situation the yellowest print will be seen to recover its original whiteness in a very short time. One or two hours are sufficient to produce the desired effect; but the print will receive no injury if it be left in [illegible] for a whole night. Nothing more is necessary to complete the work than to decant off the remaining acid, and wash away every trace of acidity by repeated affusions of pure water. The print being then left to dry (in the sun if possible) will be found white, clean [illegible], and in no respect damaged either in the texture of the paper or the tone and appearance of the impression.

"The [illegible] editor of the Journal subjoins the following note, to which collectors of prints will do well to pay attention: "As I have not repeated this process, I cannot estimate how far the presence of the lead may weaken the corrosive action of the acid on the paper, but I should be disposed to recommend a previous dilution of the acid with water. Whoever uses this process will of course make himself master of the proportion of water required to dilute the acid, by making his first trials with an old print of no value.""

PRISM, in geometry, is a body or a solid, whose two ends are any plane figures which are parallel, equal, and similar; and its sides, connecting those ends, are parallelograms. The definition of this figure in the *Encyclopædia* we must, in candour, acknowledge to be unaccountably indistinct, if not unintelligible.

PRISMOID, is a solid or body, somewhat resembling a prism, but that its ends are any dissimilar parallel plane figures of the same number of sides; the upright sides being trapezoids.—If the ends of the prismoid be bounded by dissimilar curves, it is sometimes called a *cylindroid*.

PRISON is said, in the *Encyclopædia*, to be only a place of safe custody, not a place of punishment. Such was

Prison. was, no doubt, the original intention of English prisons; but now temporary confinement is, in England as well as elsewhere, inflicted as a punishment for certain crimes. Perhaps it would be expedient to substitute this punishment more frequently than is yet done in Great Britain, for transportation and death; proportioning the length of the confinement, as well as its closeness, to the heinousness of the crime. In no country, we believe, is this more accurately done, or to better purpose, than in Pennsylvania; and surely in no country has imprisonment been more abused than in Venice under the old government.

By the laws of Pennsylvania, punishment by imprisonment is imposed, not only as an expiation of past offences, and an example to the guilty part of society, but also for another important purpose—the reformation of the criminal's morals. The regulations of the gaol are calculated to promote this effect as soon as possible; so that the building deserves the name of a *penitentiary house* more than that of a *gaol* (see PHILADELPHIA, *Encycl.*) As soon as a criminal is committed to the prison, he is made to wash; his hair is shorn; and, if not decently clothed, he is furnished with clean apparel. He is then thrown into a solitary cell, about nine feet long and four wide, where he remains debarred from the sight of every living being except his gaoler, whose duty is to attend to his bare necessities, but who is forbidden on any account to hold conversation with him. If a prisoner be at all refractory, or if the offence for which he is committed be of a very atrocious nature, he is then confined to a cell secluded even from the light of heaven. The treatment of each prisoner, during his confinement, is varied according to his crime and his subsequent repentance. Solitary confinement in a dark cell is looked upon as the severest usage; next, solitary confinement in a cell with the admission of light; next, solitary confinement in a cell, where the prisoner is allowed to do some sort of work; and, lastly, labour in company with others. The longest period of confinement is for a rape, which is not to [illegible] in ten years, nor more than twenty-one; for treason, it is not to exceed twelve, nor fall short of six years.

The prisoners are obliged to bathe twice every week, proper conveniences for that purpose being provided within the walls of the prison, and also to change their linen, with which they are regularly supplied. Those in solitary confinement are kept upon bread and water; but those who labour are allowed broth, porridge, puddings, and the like. Meat is dispensed only in small quantities, twice in the week; and on no pretence whatever is any other beverage than water suffered to be brought into the prison. Those who labour are employed in the trade to which they have been accustomed; and for those acquainted with no particular trade, some kind of work is devised which they can perform. One room is set apart for shoemakers, another for tailors, a third for carpenters, and so on. In the yards are stone cutters, smiths, nailers, &c. In a word, this prison has all the advantages of the rasping house of Amsterdam, without any of its enormous defects. See *Correction-House* in this *Suppl.*

The prison of Venice is of a very different description, and is worthy of notice here only as a curiosity in the annals of tyranny, which has, we hope, passed away with the government which contrived it. Dr Moseley, in consequence of his being an English physician (a character then highly respected in Venice), was permitted, on the 16th of September 1787, to visit the common prison, but was absolutely refused admittance into the *Sotto Piombi*, where the state prisoners were kept. As the Doctor believes that no foreigner besides himself ever witnessed the scenes, even in the common prison, which he relates, we shall give his relation in his own words. Prison.

"I was conducted (says he) through the prison by one of its inferior dependants. We had a torch with us. We crept along narrow passages as dark as pitch. In some of them two people could scarcely pass each other. The cells are made of massy marble; the architecture of the celebrated Sansovini.

"The cells are not only dark, and black as ink, but being surrounded and confined with huge walls, the smallest breath of air can scarcely find circulation in them. They are about nine feet square on the floor, arched at the top, and between six and seven feet high in the highest part. There is to each cell a round hole of eight inches diameter, through which the prisoner's daily allowance of twelve ounces of bread and a pot of water is delivered. There is a small iron door to the cell. The furniture of the cell is a little straw and a small tub; nothing else. The straw is renewed and the tub emptied through the iron door occasionally.

"The diet is ingeniously contrived for the perduration of punishment. Animal food, or a cordial nutritious regimen, in such a situation, would bring on disease, and defeat the end of this Venetian justice. Neither can the soul, if so inclined, steal away, wrapt up in slumbering delusion, or sink to rest; from the admonition of her sad existence, by the gaoler's daily return.

"I saw one man who had been in a cell thirty years; two who had been twelve years; and several who had been eight and nine years in their respective cells.

"By my taper's light I could discover the prisoners horrid countenances. They were all naked. The man who had been there thirty years, in face and body was covered with long hair. He had lost the arrangement of words and order of language. When I spoke to him, he made an unintelligible noise, and expressed fear and surprise; and, like some wild animals in desarts, which have suffered by the treachery of the human race, or have an instinctive abhorrence of it, he would have fled like lightning from me if he could.

"One whose faculties were not so obliterated; who still recollected the difference between day and night; whose eyes and ears, though long closed with a silent blank, still languished to perform their natural functions—implored, in the most piercing manner, that I would prevail on the gaoler to murder him, or to give him some instrument to destroy himself. I told him I had no power to serve him in this request. He then entreated I would use my endeavours with the inquisitors to get him hanged, or drowned in the Canal' Orfano. But even in this I could not serve him: death was a favour I had not interest enough to procure for him.

"This kindness of death, however, was, during my

ley in Venice, granted to one man, who had been 'from the cheerful ways of man cut off' thirteen years.

"Before he left his dungeon I had some conversation with him; this was six days previous to his execution. His transport at the prospect of death was surprising. He longed for the happy moment. No saint ever exhibited more fervour in anticipating the joys of a future state, than this man did at the thoughts of being released from life, during the four days mockery of his trial.

"It is in the Canal' Orfano where vessels from Turkey and the Levant perform quarantine. This place is the watery grave of many who have committed political or personal offences against the state or senate, and of many who have committed no offences at all. They are carried out of the city in the middle of the night, tied up in a sack with a large stone fastened to it, and thrown into the water. Fishermen are prohibited, on forfeiture of their lives, against fishing in this district. The pretence is the plague. This is the secret history of people being lost in Venice.

"The government, with age, grew feeble; was afraid of the discussion of legal process and of public executions; and navigated this rotten Bucentaur of the Adriatic by spies, prisons, assassination, and the Canal' Orfano.'

This is indeed a frightful narrative, and, we doubt not, true as well as frightful; but when, from the state of the Venetian prisons, the author insinuates, that Howard was not actuated by genuine benevolence, and infers, or wishes his reader to infer, that the proposal of that celebrated philanthropist for substituting solitary confinement, in many cases, for capital punishment, must have resulted from his not taking into consideration the *mind* of the criminal—the insinuation, to say the least of it, is ungenerous, and the conclusion is at war with the premises. That there was something romantic and superfluous in Howard's wanderings, we readily admit; but it seems impossible to doubt of the reality of his benevolence; and though the horrid prison of Venice, into which, as the Doctor assures us, Mr Howard never entered, was calculated to injure the body without improving the mind of the criminal, it does not follow but that solitary confinement, under such regulations as at Philadelphia, is the best means that have yet been thought of for obtaining the object nearest Howard's heart, the reformation of the morals of the criminal.

PROCYON, in astronomy, a fixed star of the second magnitude, in Canis Minor, or the Little Dog.

PROSTHAPHERESIS, in astronomy, the difference between the true and mean motion, or between the true and mean place, of a planet, or between the true and equated anomaly; called also *equation of the orbit*, or *equation of the centre*, or simply the *equation*; and it is equal to the angle formed at the planet, and subtended by the eccentricity of its orbit.

PROTRACTING, or PROTRACTION, in surveying, the act of plotting or laying down the dimensions taken in the field, by means of a protractor, &c. Protracting makes one part of surveying.

Protracting-Pin, a fine pointed pin or needle, fitted into a handle, used to prick off degrees and minutes from the limb of the protractor.

PRUNING. Under this title (*Encycl.*) it is observed, that when large branches of trees bearing stone-fruit are taken off, the trees are subject to gum and decay. For this a remedy has been invented by *Thomas Skip Dyot Bucknall*, Esq; of Conduit street, which, notwithstanding many objections made to it at first, experience has proved to be successful, and for the discovery of which the Society for the Encouragement of Arts, &c. voted the silver medal to the discoverer. It is as follows:

Cut every branch which should be taken away close to the place of its separation from the trunk; smooth it well with a knife; and then with a painter's brush smear the wound over with what Mr Bucknall calls *medicated tar*. This medicated tar is composed of one quarter of an ounce of corrosive sublimate, reduced to fine powder by beating with a wooden hammer, and then put into a three-pint earthen pipkin, with about a glass full of gin or other spirit, stirred well together, and the sublimate thus dissolved. The pipkin is then filled by degrees with vegetable or common tar, and constantly stirred, till the mixture be blended together as intimately as possible; and this quantity will at any time be sufficient for two hundred trees. To prevent danger, let the corrosive sublimate be mixed with the tar as quickly as possible after it is purchased; for, being of a very poisonous nature to all animals, it should not be suffered to lie about a house, for fear of mischief to some part of the family.

By the application of this composition, Mr Bucknall can, without the smallest danger, use the pruning hook on all kinds of trees much more freely than we have recommended its use in the article referred to. "I give no attention (says he) to fruit-branches, and wood-branches; but beg, once for all, that no branch shall ever be shortened, unless for the figure of the tree, and then constantly taken off close to the separation, by which means the wound soon heals. The more the range of the branches shoots circularly, a little inclining upwards, the more equally will the sap be distributed, and the better will the tree bear; for, from that circumstance, the sap is more evenly impelled to every part. Do not let the ranges of branches be too near each other; for remember all the fruit and the leaves should have their full share of the sun; and where it suits let the middle of the tree be free from wood, so that no branch shall ever cross another, but all the extreme ends point outwards."

PULO, the name of several islands of Asia, in the Indian Ocean; the principal of which alone, according to Dr Brooke's, is inhabited. This is the island

Pulo-Condore, which, being visited by Lord Macartney as he sailed to China, is thus described by Sir George Staunton. "It has the advantage of convenient anchoring places in either monsoon. The squadron accordingly stopped on the 17th of May, in a spacious bay on the eastern side of the island; and came to anchor at the entrance of its southern extremity, as the water shoaled there to five fathoms and a half, occasioned by a bank which stretches across two-thirds of the entrance. It was found afterwards, that beyond the bank there is a safe passage to the inner part of the bay, the north of which is sheltered by a small island lying to the eastward. The whole of the bay is formed by four small islands, which approach so nearly to each other, as to appear, from several points, to join.

2 They

They all seem to be the rude fragments of primitive mountains, separated from the great continent in the lapse of time. The principal island is eleven or twelve miles in length, and about three in breadth. It is in the form of a crescent, and consists of a ridge of peaked hills. Its latitude, as calculated from a meridional observation, is 8° 40′ north from the equator; and its longitude, according to a good chronometer, is 105° 55′ east from Greenwich.

"The English had a settlement on Condore until the beginning of the present century, when some Malay soldiers in their pay, in resentment for some unjustifiable treatment, murdered their superiors, with the exception of a very few who escaped off the island, where no Europeans have since resided. At the bottom of the bay was a village situated close to a fine sandy beach, with a long range of cocoa-nut trees before it, and it was defended from the north-east sea by a reef of coral rocks, within which was good anchorage for small vessels, and an easy landing for boats. A party went on shore from Lord Macartney's squadron, with the precaution, however, of being armed, as large canoes were espied within the reef, which might have been Malay pirates. Several of the inhabitants came to the beach, and with the appearance of much urbanity of manners welcomed them on shore, and conducted them to the house of their chief. It was a neat bamboo cabin, larger than the rest. The floor was elevated a few feet above the ground, and strewed with mats, on which were assembled as many men as the place could hold. It was apparently on the occasion of some festival, or pleasurable meeting. There was in one of the apartments an altar decorated with images, and the partitions hung with figures of monstrous deities; but the countenances and deportment of the people conveyed no idea of religious awe, and no person was seen in the posture of prayer or adoration. A few spears stood against the wall with their points downwards, together with some matchlocks and a swivel gun. The dress of these people was composed chiefly of blue cotton worn loosely about them; and their flat faces and little eyes denoted a Chinese origin or relation. Several long slips of paper, hanging from the ceiling, were covered with columns of Chinese writing. One of the missionaries, who was of the party, could not, however, in any degree, understand their conversation; but when the words were written, they instantly became intelligible to him. Though their colloquial language was altogether different from what is spoken in China, yet the characters were all Chinese; and the fact was clearly ascertained on this occasion, that those characters have an equal advantage with Arabic numbers, of which the figures convey the same meaning wherever known; whereas the letters of other languages denote not things, but elementary sounds, which combined variously together, form words, or more complicated sounds, conveying different ideas in different languages, though the form of their alphabet be the same.

"The inhabitants of Pulo Condore were, it seems, Cochin-Chinese, with their descendants, who fled from their own country, in consequence of their attachment to one of its sovereigns, dethroned by several of his own subjects. It was proposed to purchase provisions here; and the people promised to have the specified quantity ready, if possible, the next day, when it was intended, if the weather should be favourable, to land the invalids. The next morning was fair in the beginning; and a party of pleasure was made from the Hindostan to a small island close to Pulo Condore. They were scarcely arrived upon it when the weather began to lower; and the boat set off on its return, in order to reach the ship before the impending storm should begin.

"With difficulty it reached the ship; and as soon as the weather became fair, messengers were dispatched on shore to receive and pay for the provisions promised. When they arrived at the village, they were astonished to find it abandoned. The houses were left open, and none of the effects, except some arms, that had on the first visit been perceived within them, or even of the poultry feeding about the doors, were taken away. In the principal cabin a paper was found, in the Chinese language, of which the literal translation purported, as nearly as it could be made, that 'the people of the island were few in number, and very poor, yet honest, and incapable of doing mischief; but felt much terror at the arrival of such great ships and powerful persons, especially as not being able to satisfy their wants in regard to the quantity of cattle and other provisions, of which the poor inhabitants of Pulo Condore had scarcely any to supply, and consequently could not give the expected satisfaction. They therefore, through dread and apprehension, resolved to fly to preserve their lives. That they supplicate the great people to have pity on them; that they left all they had behind them, and only requested that their cabins might not be burnt; and conclude by prostrating themselves to the great people a hundred times.'

"The writers of this letter had probably received ill treatment from other strangers. It was determined that they should not continue to think ill of all who came to visit them. On their return they were perhaps as much surprised to find their houses still entire, as their visitors had been who found they were deserted. Nothing was disturbed; and a small present, likely to be acceptable to the chief, was left for him in the principal dwelling, with a Chinese letter, signifying that 'the ships and people were English, who called merely for refreshment, and on fair terms of purchase, without any ill intention; being a civilized nation, endowed with principles of humanity, which did not allow them to plunder or injure others who happened to be weaker or fewer than themselves."

Pulo Lingen, another of this cluster, is likewise a considerable island, remarkable for a mountain in its centre, terminating in a fork like Parnassus; but to which the unpoetical seamen bestow the name of *asses ears*. Every day presented new islands to the view, displaying a vast variety in form, size, and colour. Some isolated, and some collected in clusters. Many were clothed with verdure; some had tall trees growing on them; others were mere rocks, the resort of innumerable birds, and whitened with their dung.

PUNCTUATION, in grammar, is an art with which we have said, in the *Encyclopædia*, that the ancients were entirely unacquainted. Candour obliges us to confess that this was said rashly. A learned writer, in the Monthly Magazine for September 179[illegible], who subscribes J. Warburton, has proved, we think completely, that the art is not wholly modern; and we shall

shall lay his proofs, in his own words, before our readers.

"Some species of pauses and divisions of sentences in speaking and writing must have been coeval with the knowledge of communicating ideas by sound or by symbols. Suidas * says, that the *period* and the *colon* were discovered and explained by Thrasymacus, about 380 years before the Christian æra. Cicero † says, that Thrasymacus was the first who studied oratorical numbers, which entirely consisted in the artificial structure of periods and colons. It appears from a passage in Aristotle ‡, that punctuation was known in his time. The learned Dr Edward Bernard § refers the knowledge of pointing to the time of that philosopher, and says, that it consisted in the different positions of one single point. At the bottom of a letter, thus, (A.) it was equivalent to a comma; in the middle (A·) it was equal to a colon; at the top (A˙) it denoted a period, or the conclusion of a sentence.

* Qui primus periodum et colon monstravit *Suidas in Thrasymacho*.
† *Cicero Orat.* § 33.
‡ *Rhet* Lib iii c 5.
§ *Bern Orbis erud. Literat* tab 3. edit 1689.

"This mode was easily practised in Greek manuscripts, while they were written in capitals. But when the small letters were adopted, that is, about the 9th century, this distinction could not be observed; a change was therefore made in the scheme of punctuation. *Unciales literas hodierno usu dicimus eas in vetustis codicibus, quæ priscam formam servant, ac solutæ sunt, nec mutuo colligantur. Hujus modi literæ unciales observantur in libris omnibus ad nonum usque sæculum*—Montf. Palæog. Recens. p. xii.

"According to Cicero, the ancient Romans, as well as the Greeks, made use of points. He mentions them under the appellation of *librariorum notæ*; and in several parts of his works he speaks of '*interpunctæ clausulæ in orationibus*,' of '*clausulæ atque interpuncta verborum*,' of '*interpunctiones verborum*,' &c *.

"Seneca, who died A. D. 65, expressly says, that Latin writers, in his time, had been used to punctuation. '*Nos* †, *cum scribimus interpungere consuevimus*.' Muretus and Lipsius imagined that these words alluded to the insertion of a point after each word: but they certainly were mistaken; for they must necessarily refer to marks of punctuation in the division of sentences, because in the passage in which these words occur, Seneca is speaking of one Q. Haterius, who made no pauses in his orations.

* *Cic de Orat.* l. iii. § 2? ibid ? *Orat pro Murena*, § 25
† *Senec. Epist.*

"According to Suetonius, in his *Illust. Gram.* Valerius Probus procured copies of many old books, and employed himself in correcting, pointing, and illustrating them; devoting his time to this and no other part of grammar. *Multa exemplaria contracta emendare, ac distinguere et adnotare curavit; soli huic, nec ulli prætera, grammatices parti deditus*.

"It appears from hence, that in the time of Probus, or about the year 68, Latin manuscripts had not been usually pointed, and that grammarians made it their business to supply this deficiency.

"Quintilian, who wrote his celebrated treatise on Oratory, about the year 88, speaks of commas, colons, and periods; but it must be observed, that by these terms he means clauses, members, and complete sentences, and not the marks of punctuation ‡.

"Ælius Donatus § published a treatise on Grammar in the 4th century, in which he explains the *distinctio*, the *media distinctio*, and the *subdistinctio*; that is, the use of a single point in the various positions already mentioned.

‡ *Quint.* l. ix. c. 4.
§ A. D. 340.

"Jerom *, who had been the pupil of Donatus, in his Latin Version of the Scriptures, made use of certain distinctions or divisions, which he calls *cola* and *commata*. It has, however, been thought probable, that these divisions were not made by the addition of any points or stops; but were formed by writing, in one line, as many words as constituted a clause, equivalent to what we distinguish by a comma or a colon. These divisions were called στίχοι or ῥήματα; and had the appearance of short irregular verses in poetry. There are some Greek manuscripts still extant, which are written in this manner †."

* *Hieron. Præf in Esaiam. Vide etiam. Præf. in Josuam*, &c tom.iii. p. 26.
† *Vide Montf. Palæog. Græca*, lib. iii. c. 4.

Mr Warburton says, that the best treatise upon punctuation that he has seen, was published some years since by an anonymous author, and dedicated to Sir Clifton Wintringham, Bart. With that treatise we are not acquainted; but we do not think that the art of punctuation can be taught by rules. The only way to acquire it is to observe attentively how the most perspicuous writers dispose of their periods, colons, semicolons, and commas. This will make us acquainted with the importance of each; and then every writer, who knows his own meaning, must be capable of pointing his own pages more correctly than any other man.

PYRAMIDOID, is sometimes used for the parabolic spindle, or the solid formed by the rotation of a semiparabola about its base or greatest ordinate. See PARABOLIC *Spindle*.

PYRITES. See MINERALOGY in this *Suppl.*—In the third volume of Mr Nicholson's Philosophical Journal, we have a method of making artificial pyrites, which we shall give in the words of the author.

"I impregnated water (says he) very strongly with carbonic acid, and introducing some iron filings, I continued the impregnation for a day or two, and afterwards allowed the water to stand in a well corked bottle for some days, till the acid had taken up as much iron as possible. I then poured it into an aerating apparatus; threw up the hepatic gas from sulphuret of potash and sulphuric acid; and after having agitated the water till it had got a good dose of the gas, I poured the water into a large bason: this was in the evening, and next morning when I looked at it I found it covered with a pretty thick film of a most beautiful variegated pyrites. I had so little of it, that the only proof I had of its being this substance was, that it was ignited on its being placed on a hot poker."

QUADRATURE,

Q.

Quadrature.

QUADRATURE, in geometry (fee that article, and likewife FLUXIONS, *Encycl.*), has employed the time and ingenuity of fome of the moft eminent mathematicians both of ancient and of modern times. Dr Halley's method of computing the ratio of the diameter of the circle to its circumference, was confidered by himfelf, and other learned mathematicians, as the eafieft the problem admits of. And although, in the courfe of a century, much eafier methods have been difcovered, ftill a celebrated mathematician of our own times has expreffed an opinion, that no other aliquot part of the circumference of a circle can be fo eafily computed by means of its tangent as that which was chofen by Dr Halley, viz. the arch of 30 degrees. Without taking upon him to determine whether this opinion be juft or not, the Rev. John Hellins has fhewn how the feries by which Dr Halley computed the ratio of the diameter to the circumference of the circle may be transformed into others of fwifter convergency, and which, on account of the fucceffive powers of $\frac{1}{10}$ which occur in them, admit of an eafy fummation. We fhall give the memoir in the author's own words.

"1. The propofed transformation is obtained by means of different forms in which the fluents of fome fluxions may be expreffed; and to proceed with greater clearnefs, "I will here (fays Mr Hellins) fet down the fluxion in a general form, and its fluent, in the two feries which are ufed in the following particular inftance, and may be applied with advantage in fimilar cafes.

"2. The fluent of $\frac{x^{m-1}\dot{x}}{1-x^n}$ is $= \frac{x^m}{m} + \frac{x^{m+n}}{m+n} + \frac{x^{m+2n}}{m+2n} + \frac{x^{m+3n}}{m+3n}$, &c. which feries, being of the fimpleft form which the fluent feems to admit, was firft difcovered, and probably is the moft generally ufeful. But it has alfo been found, that the fluent of the fame fluxion may be expreffed in feries of other forms, which, though lefs fimple than that above written, yet have their particular advantages. Amongft thofe other forms of feries which the fluent admits of, that which fuits my prefent purpofe is $\frac{x^m}{m.\overline{1-x^n}} - \frac{nx^{m+n}}{m.\overline{m+n}.\overline{1-x^n}|^2} + \frac{n.2n.x^{m+2n}}{m.\overline{m+n}.\overline{m+2n}.\overline{1-x^n}|^3} - \frac{n.2n.3n.x^{m+3n}}{m.\overline{m+n}.\overline{m+2n}.\overline{m+3n}.\overline{1-x^n}|^4}$ + &c. which, to fay nothing of other methods, may eafily be inveftigated by the rule given in p. 64. of the third edition of *Emerfon's Fluxions*; or its equality with the former feries may be proved by algebra.

"3. On account of the fign — before x^n, in the laft feries, it may be proper to remark, that its convergency, by a geometrical progreffion, will not ceafe till $\frac{x^n}{1-x^n}$ becomes $= 1$, or x becomes $= \sqrt[n]{\frac{1}{2}}$; and that when x is a fmall quantity, and n a large number, this feries will converge almoft as fwiftly as the former. For inftance, if x be $= \sqrt{\frac{1}{3}}$, and $n = 8$, which are the values in the following cafe, the former feries will converge by the quantity $x^n = \sqrt{\frac{1}{3}}|^8 = \frac{1}{81}$, and this feries by the quantity $\frac{x^n}{1-x^n} = \frac{\frac{1}{81}}{1-\frac{1}{81}} = \frac{1}{80}$; where the difference in convergency will be but little, and the divifions by 80 eafier than thofe by 81.

"4. With refpect to the indices m and n, as they are here fuppofed to be affirmative whole numbers, and will be fo in the ufe I am about to make of them. the reader need not be detained with any obfervations on the cafes in which thefe fluents will fail, when the indices have contrary figns.

"5. It may be proper further to remark, that by putting $\frac{x^n}{1-x^n} = z$, and calling the firft, fecond, third, &c. terms of the feries $\frac{x^m}{m.\overline{1-x^n}} - \frac{nx^{m+n}}{m.\overline{m+n}.\overline{1-x^n}|^2} + \frac{n.2nx^{m+2n}}{m.\overline{m+n}.\overline{m+2n}.\overline{1-x^n}|^3}$ + &c. A, B, C, &c. refpectively, the feries will be expreffed in the concife and elegant notation of Sir Ifaac Newton, viz. $\frac{x^m}{m.\overline{1-x^n}} - \frac{nzA}{m+n} + \frac{2nzB}{m+2n} - \frac{3nzC}{m+3n}$ + &c. which is well adapted to arithmetical calculation.

"6. I come now to the transformation propofed, which will appear very eafy, as foon as the common feries, expreffing the length of an arch in terms of its tangent, is properly arranged.

"If the radius of a circle be 1, and the tangent of an arch of it be called t, it is well known that the length of that arch will be $= t - \frac{t^3}{3} + \frac{t^5}{5} - \frac{t^7}{7} + \frac{t^9}{9} - \frac{t^{11}}{11}$ + &c. Now, if the affirmative terms of this feries be written in one line, and the negative ones in another, the arch will be

$$= \begin{cases} t + \frac{t^5}{5} + \frac{t^9}{9} + \frac{t^{13}}{13} + \frac{t^{17}}{17} + \text{\&c.} \\ -\frac{t^3}{3} - \frac{t^7}{7} - \frac{t^{11}}{11} - \frac{t^{15}}{15} - \frac{t^{19}}{19} - \text{\&c.} \end{cases}$$

And if, again, the firft, third, fifth, &c. term of each of thefe feries be written in one line, and the fecond, fourth, fixth, &c. in another, the fame arch will be expreffed thus:

$$= \begin{cases} + \begin{cases} t + \frac{t^9}{9} + \frac{t^{17}}{17} + \frac{t^{25}}{25} + \frac{t^{33}}{33} + \text{\&c.} \\ \frac{t^5}{5} + \frac{t^{13}}{13} + \frac{t^{21}}{21} + \frac{t^{29}}{29} + \frac{t^{37}}{37} + \text{\&c.} \end{cases} \\ - \begin{cases} \frac{t^3}{3} + \frac{t^{11}}{11} + \frac{t^{19}}{19} + \frac{t^{27}}{27} + \frac{t^{35}}{35} + \text{\&c.} \\ \frac{t^7}{7} + \frac{t^{15}}{15} + \frac{t^{23}}{23} + \frac{t^{31}}{31} + \frac{t^{39}}{39} + \text{\&c.} \end{cases} \end{cases}$$

All which feries are evidently of the firft form [illegible] ticle 2. and therefore their values may be expreffed in the fecond form there given, or more neatly the Newtonian notation mentioned in art. 5. In each of thefe feries the value of n is 8:

And the value of m, $\begin{cases} \text{in the first series, is } 1; \\ \text{in the second series, is } 5; \\ \text{in the third series, is } 3; \\ \text{in the fourth series, is } 7. \end{cases}$

"If now we take $t = \sqrt{\frac{1}{3}}$, the tangent of 30°, which was chosen by Dr Halley, we shall have the arch of 30°

$$= \begin{cases} + \begin{cases} \frac{1}{\sqrt{3}} \times : 1 + \frac{1}{9.81} + \frac{1}{17.81^2} + \frac{1}{25.81^3} + \frac{1}{33.81^4}, \text{ \&c.} \\ \frac{1}{9\sqrt{3}} \times : \frac{1}{5} + \frac{1}{13.81} + \frac{1}{21.81^2} + \frac{1}{29.81^3} + \frac{1}{37.81^4}, \text{ \&c.} \end{cases} \\ - \begin{cases} \frac{1}{3\sqrt{3}} \times : \frac{1}{3} + \frac{1}{11.81} + \frac{1}{19.81^2} + \frac{1}{27.81^3} + \frac{1}{35.81^4}, \text{ \&c.} \\ \frac{1}{27\sqrt{3}} \times : \frac{1}{7} + \frac{1}{15.81} + \frac{1}{23.81^2} + \frac{1}{31.81^3} + \frac{1}{39.81^4}, \text{ \&c.} \end{cases} \end{cases}$$

Six times this quantity will be = the semicircumference when radius is 1, and = the whole circumference when the diameter is 1. If therefore we multiply the last series by 6, and write $\sqrt{12}$ for $\frac{6}{\sqrt{3}}$, and express their value in the form given in art. 5. we shall have the circumference of a circle whose diameter is 1,

$$= \begin{cases} + \begin{cases} \frac{81\sqrt{12}}{80} - \frac{8A}{9.80} + \frac{16B}{17.80} - \frac{24C}{25.80} + \frac{32D}{33.80}, \text{ \&c.} \\ \frac{81\sqrt{12}}{5.9.80} - \frac{8A}{13.80} + \frac{16B}{21.80} - \frac{24C}{29.80} + \frac{32D}{37.80}, \text{ \&c.} \end{cases} \\ - \begin{cases} \frac{81\sqrt{12}}{3.3.80} - \frac{8A}{11.80} + \frac{16B}{19.80} - \frac{24C}{27.80} + \frac{32D}{35.80}, \text{ \&c.} \\ \frac{81\sqrt{12}}{7.27.80} - \frac{8A}{15.80} + \frac{16B}{23.80} - \frac{24C}{31.80} + \frac{32D}{39.80}, \text{ \&c.} \end{cases} \end{cases}$$

"7. All these new series, it is evident, converge somewhat swifter than by the powers of 80. For in the first series, which has the slowest convergency, the coefficients $\frac{8}{9}$, $\frac{16}{17}$, $\frac{24}{25}$, &c. are each of them less than 1; so that its convergency is somewhat swifter than by the powers of 80.

"8. But another advantage of these new series is, that the numerator and denominator of every term except the first, in each of them, is divisible by 8; in consequence of which, the arithmetical operation by them is much facilitated, the division by 80 being exchanged for a division by 10, which is no more than removing the decimal point. These series, then, when the factors which are common to both numerators and denominators are expunged, will stand as below (each of which still converging somewhat quicker than by the powers of 80), and we shall have the circumference of a circle whose diameter is 1,

$$= \begin{cases} + \begin{cases} \frac{81\sqrt{12}}{80} - \frac{A}{9.10} + \frac{2B}{17.10} - \frac{3C}{25.10} + \frac{4D}{33.10}, \text{ \&c.} \\ \frac{9\sqrt{12}}{400} - \frac{A}{13.10} + \frac{2B}{21.10} - \frac{3C}{29.10} + \frac{4D}{37.10}, \text{ \&c.} \end{cases} \\ - \begin{cases} \frac{9\sqrt{12}}{80} - \frac{A}{11.10} + \frac{2B}{19.10} - \frac{3C}{27.10} + \frac{4D}{35.10}, \text{ \&c.} \\ \frac{3\sqrt{12}}{7.80} - \frac{A}{15.10} + \frac{2B}{23.10} - \frac{3C}{31.10} + \frac{4D}{39.10}, \text{ \&c.} \end{cases} \end{cases}$$

"By which series the arithmetical computation will be much more easy than by the original series."

Quadrature Lines, or *Lines of Quadrature*, are two lines often placed on Gunter's sector. They are marked with the letter Q, and the figures 5, 6, 7, 8, 9, 10; of which Q denotes the side of a square, and the figures denote the sides of polygons of 5, 6, 7, &c. sides. Also S denotes the semidiameter of a circle, and 90 a line equal to the quadrant or 90° in circumference.

QUADRIPARTITION, is the dividing by 4, or into four equal parts. Hence *quadripartite*, &c, the 4th part, or something parted into four.

QUADRUPLE, is four fold, or something taken four times, or multiplied by 4; and so is the converse of quadripartition.

QUART, a measure of capacity, being the quarter or 4th part of some other measure. The English quart is the 4th part of the gallon, and contains two pints. The Roman quart, or quartarius, was the 4th part of their congius. The French, besides their quart or pot of two pints, have various other quarts, distinguished by the whole of which they are quarters; as *quart de muid*, and *quart de boisseau*.

QUARTILE, an aspect of the planets when they are at the distance of three signs or 90° from each other; and is denoted by the character □.

QUELPAERT, an island lying in the mouth of the channel of Japan, and subject to the king of Corea (See that article *Encycl.*) Till the last voyage of La Perouse, this island was known to Europeans only by the wreck of the Dutch ship Sparrow-hawk in 1635. On the 21st of May 1787, the French Commodore made this island, and determined the south point of it to be in Lat. 33° 14′ north, and in Lon. 124° 15′ east from Paris. He ran along the whole south east side, at six leagues distance, and says that it is scarcely possible to find an island which affords a finer aspect; a peak of about a thousand toises, which is visible at the distance of eighteen or twenty leagues, occupies the middle of the island, of which it is doubtless the reservoir; the land gradually slopes towards the sea, whence the habitations appear as an amphitheatre. The soil seemed to be cultivated to a very great height. By the assistance of glasses was perceived the division of fields; they were very much parcelled out, which is the strongest proof of a great population. The very varied gradation of colours, from the different states of cultivation, rendered the view of this island still more agreeable. Unfortunately, it belongs to a people who are prohibited from all communication with strangers, and who detain in slavery those who have the misfortune to be shipwrecked on these coasts. Some of the Dutchmen of the ship Sparrow-hawk, after a captivity of eighteen years there, during which they received many bastinadoes, found means to take away a bark, and to cross to Japan, from which they arrived at Batavia, and afterwards at Amsterdam.

QUEUE D'ARONDE, or *Swallow's Tail*, in fortification, is a detached or outwork, whose sides spread or open towards the campaign, or draw narrower and closer towards the gorge. Of this kind are either single or double tenailles, and some horn-works, whose sides are not parallel, but are narrow at the gorge, and open at the head, like the figure of a swallow's tail. On the contrary, when the sides are less than the gorge, the work is called *contre queue d'aronde*.

Queue, Quintal

Queue d'aronde, in carpentry, a method of jointing, called also *dove-tailing*.

QUINTAL, the weight of a hundred pounds, in most countries: but in England it is the hundred weight, or 112 pounds. Quintal was also formerly used for a weight of lead, iron, or other common metal, usually equal to a hundred pounds, at 6 score to the hundred.

Quintile

QUINTILE, in astronomy, an aspect of the planets when they are distant the 5th part of the zodiac, or 72 degrees; and is marked thus, C, or Q.

R.

Rachitis.

RACHITIS, Rickets (See Medicine-*Index*, *Encycl.*), is a disease so formidable to children, that we believe no parent will think the following abstract of *Bonhomme's* memoir on the nature and treatment of it too long even for this *Supplement*.

The change which the bones undergo in this disorder, has long been attributed to the action of an acid on their substance; but this supposition was grounded on mere conjecture and remote analogy. Bonhomme holds the same opinion on better grounds; and the principal notions which constitute the basis of his memoir are the following:

1. According to him, the nature of the rachitic disorder arises, on the one hand, from the developement of an acid approaching in its properties to the vegetable acids, particularly the oxalic; and, on the other, from the defect of phosphoric acid, of which the combination with the animal calcareous earth forms the natural basis of the bones, and gives them their solidity. Whence it follows, that the indication resulting from this proposition, if once adopted, would be, that the treatment of rachitis must depend on two principal points, namely, to prevent the developement of the oxalic acid, and to re-establish the combination of the phosphoric acid with the basis of the bones to which they owe their solidity.

2. The author proves, by experiments and observations, in the first place, that alkaline lotions of the parts affected with rachitis contribute to their cure; next, that the calcareous phosphate taken internally is really transmitted by the lymphatic passages, and contributes to ossification; and, lastly, that the internal use of calcareous phosphate, whether alone or combined with the phosphate of soda, powerfully contributes to restore the natural proportions in the substance of the bones, and accelerate the cure of rachitis.

With regard to the author's endeavours to prove that the calcareous acid is wanting in the bones of those who are disordered with rachitis, and that the developement of oxalic acid contributes to the disease, we must not conceal that his memoir contains views rather than absolute proofs of these two positions. He declares, himself, he was not provided with the necessary means to establish an exact and complete analysis. He therefore presents his ideas, in this respect, merely as conjectures approaching to the truth.

The effect of the action of acids upon bones was before known; that is to say, that when deprived of calcareous phosphate, and reduced to the gelatinous parenchyma which forms one of their elements, they lose their consistence, and become flexible. Hence it was already conjectured by various physicians, that the rachitis was the effect of a peculiar acid.

Rachitis.

A disposition to acescence in the first passages is observable in all infants. The odour which characterizes this acescence is often manifest in their breath, and even their perspiration. The bile corrects this disposition; but in general the bile is wanting in rachitic infants. It does not colour their excrements, and the acids accordingly are developed in a very decided manner. They disturb the circulation, and attack and soften the bones. As it is by defect of animalization that these acids develope themselves, it follows that their character is analogous to the fermentescible vegetable acids, and more or less to the oxalic acid; and that, on the contrary, the animal acid or phosphoric acid ceases to be formed, and to unite with the animal calcareous earth; whence they are deprived of the principle of their solidity. This is the theory of Citizen Bonhomme.

In order to establish this doctrine upon precise experiments, it was requisite to analyse rachitic bones comparatively with those of healthy individuals of the same age; and as it is known that the urine of rachitic subjects deposites a great quantity of a substance of sparing solubility and earthy appearance, it would have been advantageous to have joined a complete analysis of this urine and its sediment. Citizen Bonhomme, not being provided with the means sufficient to make these analyses, and being besides of opinion that such rachitic bones as are destroyed by this malady exist in a progressive state of change, which might render their analysis scarcely susceptible of comparison, limited himself to a collection of some of the most remarkable phenomena of the urine, of the aged, the adult, and infants in the healthy state, of infants in the rachitic state, and of patients after the perfect cure of this disorder. From these observations he has deduced several important results.

It is known, that when the urine contains disengaged phosphoric acid, as happens to aged individuals, and in some peculiar circumstances of the system, if lime water be poured in, there is a speedy deposition of calcareous phosphate. It is also known, that when a solution of the nitrate of mercury is poured to the fresh urine of adults, a rose-coloured precipitate is formed, which is a phosphate of mercury produced by the decomposition of the phosphates contained in the urine. These two proofs are therefore extremely proper to ascertain the presence of phosphoric acid, whether free or combined, in

in a fluid which in its natural state contains a remarkable proportion. Besides this principle, the urine deposits more or less of sediment, either gelatinous or of an earthy appearance; and, lastly, by evaporation, a saponaceous and saline extract, in greater or less abundance, is obtained by evaporation. By means of these four methods of examination, the author has ascertained the following facts:

1. In the healthy state, the sediment naturally deposited by urine is almost totally gelatinous in the infant and the adult, and in the aged individual it is surcharged with an abundant sediment of an earthy appearance similar to the earth of bones, which consequently is calcareous phosphate. 2. The quantity of brown saponaceous saline extract afforded by evaporation is greater in proportion to the age. 3. The presence of disengaged phosphoric acid, as shewn by lime water, is none in the urine of infants, scarcely perceptible in that of adults, but very remarkable in that of old men. For two ounces of this last urine afforded by this means ten grains of phosphate of lime. 4. The decomposition of the phosphates by nitrate of mercury is not seen in the urine of infants; an abundant precipitate of a light rose colour is produced in this way from the urine of adults; and in that of old men this precipitate is always of a grey colour, and very abundant. Hence Citizen Bonhomme concludes, that the phosphoric acid, whether at liberty or combined, does exist in the urine of healthy individuals in proportion to the destruction of the solids by age, and that it increases with the age.

With regard to the urine of rachitic subjects, the most remarkable facts are, 1. The abundant and apparently earthy sediment it deposits (spontaneously) is different from that of old men, by its colour, which is grey, and does not resemble phosphate of lime, and also by its much greater quantity. For a pound of this urine let fall two gros, whereas the same quantity of the urine of old men deposited only 45 grains. 2. The extract left by evaporation is likewise much more considerable than in other urine. It is one-third more in quantity than the extract afforded even by the urine of aged persons.

From these two first observations it follows, that the solids in rachitic subjects are destroyed with much more rapidity than even in old men; and that they afford a much more abundant portion of waste to the urine.

3. The light deposition occasioned by lime water in the urine of rachitic subjects is very small in quantity, brown, gelatinous when fresh, and pulverulent when dry. It does not at all resemble calcareous phosphate. 4. The deposition formed by the solution of mercurial nitrate is not abundant, neither of a rose colour as in the urine of adults, nor grey like that of old men. It is always white, and consequently has no external resemblance to the phosphate of mercury. The author affirms that it resembles a mercurial oxalate. Lastly, the urine of the same rachitic subjects when cured, exhibits again all the characters observed in the urine of healthy children. We shall not add to the reflections of the author. In effect, though these first observations are curious, they are incomplete. We offer them to physicians simply as the elements of an investigation which it is of importance to continue and bring to perfection. We shall therefore proceed to the curative and experimental parts of the memoir.

One of the facts which it was of the utmost importance to establish, was the transition of the calcareous phosphate from the intestinal passages, into those of circulation and secretion. Fourcroy had already well ascertained that the serum of milk contains this salt naturally. Vauquelin had proved its existence, as well as that of pure soda, in the seminal fluid; but was it possible that it could pass unaltered from the stomach and intestines into the vessels which contain the blood and lymph? Could it by this means apply itself to the bones? This was to be ascertained by experiments; and the following are the experiments made by Bonhomme for that purpose. We give them in a translation of his own words.

"I caused (says he) several young fowls of the same incubation to be fed in different manners. Some received the usual food without any mixture; others received daily a certain quantity of calcareous phosphate mixed in the same paste as formed the support of the others; and, lastly, one of them was fed with variations in the use of the mixture: the calcareous phosphate was sometimes given and sometimes suspended. When these fowls, after two months, had acquired their ordinary growth, I examined and carefully compared the state of their bones. The progress of the ossification in the epiphyses was various according to the nature of the food the animal had received. The bones of the last fowl, which had received the phosphate only from time to time, were rather more advanced than the bones of those which had been fed without mixture. The bones of those fowls which had been habitually fed with the mixture were evidently more solid, and their epiphyses were much less perceptible. Simple inspection was sufficient to shew these differences when the bones were mixed together.

"I had fed several young fowls of the same incubation according to another plan. Some were fed on a simple paste, without mixture; for others it was mixed with pulverised madder-root; and a third composition was made of this last paste and calcareous phosphate. This was also given habitually to other fowls. When, after two months I examined the progress of ossification in the bones of these different animals, I easily perceived the red traces of the madder in the ossified parts of all those which had used it; but I observed, that the ossification was not more advanced by the simple mixture of this root than by the ordinary food: on the contrary, the bones of those fowls which had swallowed the phosphate mixed with madder were much more solid than the others. The red colour served admirably to distinguish the extremities of the long bones from their epiphyses. After an exact comparison, there could be no doubt of the efficacy of calcareous phosphate in favour of the progress of ossification. The virtue of the madder seemed confined to that of giving colour to the ossified parts."

From these experiments, it was natural to make the trial of calcareous phosphate in addition to the remedies made use of in the treatment of rachitic subjects. Here follows what the author himself says of two remarkable instances in which the calcareous phosphate was administered with success:

"The daughter of Mr Ranchon watch-maker, aged two years and a half, walked with a feeble and tottering pace, and the extremities of all her bones presented epiphyses very

 very prominent. In this situation she exhibited the appearance of imperfect rachitis, or the first period of this disorder. Alkaline lotions, which I immediately advised, were attended with a good effect. Her sleep became more firm; and as the first passages were in a good state, I gave, without internal preparation, one scruple of a mixture of equal parts of phosphate of lime and phosphate of soda twice a day. In the course of three weeks her legs were perfectly restored; and this amiable infant has ever since had the satisfaction to run with spirit and agility.

"A female infant, of the name of Boiard, aged four years, had experienced from her birth the most decided symptoms of rachitis. The protuberance of the epiphyses and tumefaction of the abdomen first indicated the disease. The impossibility of supporting herself and walking at the usual age confirmed these unfortunate symptoms. By degrees the glands of the neck and of the mesentery became swelled; the teeth were blackened, became carious, and were not replaced. This situation became still more afflicting by crises almost periodical at an interval of three or four weeks. At these afflicting periods, a fever of considerable strength, cardialgia, and even convulsions, particularly in the night, were observed. The termination of each paroxysm was announced or ascertained by abundant stools, and the evacuation of urine strongly charged with an earthy sediment. The imprudent exhibition of a purge at the beginning of one of these crises had nearly deprived the patient of her life. In this state it was that I beheld her for the first time in the month of January 1791. The alkaline lotion was the only remedy the mother adopted in the first instance, and it produced a remarkable effect. After eight days the infant was so much better as to be able to support herself. The remedy was then laid aside, and eight days afterwards the child was incapable of standing without support. The use of the alkaline solution being renewed, was attended with the same success, and its discontinuance was again followed by the complete return of all the symptoms. In the first days of March, the other remedies I had advised were exhibited. The constipation which had always existed became less, and the following crisis was effected without pain. And at length the convulsions, the pains, and the crises disappeared; but the impossibility of walking still remained. At this time, namely on the second of May, I gave the child the phosphate of soda and calcareous phosphate mixed together, in the dose of half a dram twice a-day. At the end of the month she was able to stand upright, leaning against a chair, and the swellings began to diminish. She continued for a long time afterwards to take the mixture of the phosphates. I likewise gave her occasionally one grain of the extract of bile, prepared with spirit of wine; and at length in the month of July I had the pleasure to see the patient run and play in the middle of the street with the other children of her own age, &c."

The author gives other instances of this medicine being administered with complete success to rachitic children, and one in which it was attended with the best effects in a case of incurvated spine. These it is needless to insert, because we trust that none of our less learned readers will have recourse to the medicine without the advice of a physician; and to him an enumeration of cases could serve no purpose. It may be proper, however, as alkaline lotions and their beneficial effects are mentioned, to give here the author's account of the lotion which he used.

"In ordinary cases of rachitis, particularly at the commencement of the disorder, it is of advantage to use a simple solution of pot-ash to wash the parts affected. This solution is made by dissolving from half an ounce to an ounce of purified pot-ash in a pound of distilled or very pure spring water. When it is to be used, the skin must first be rubbed with a dry cloth or a piece of fine flannel. After this precaution, the diseased extremities are to be washed carefully with the warm solution, and at length wiped, so as to leave no trace of moisture. This practice and washing must be repeated at least twice a-day. I can affirm, from repeated trials, that it will always be attended with success."

In a note on this passage, M. Hallé, who analysed the memoir at the desire of the Society of Medicine at Paris, justly observes, that as pure potash, or the vegetable alkali, is a most powerful caustic, it cannot be used in these proportions; adding, that he found one-eighth part of the salt here indicated to form too strong a lotion for the skin of an infant. M. Bonhomme, upon enquiry being made, informed him, that the potash which he used was that of the shops, which is very far from being pure; and Mr Nicholson conjectures that it was the common salt of tartar of our shops. This, we think, extremely probable, especially as M. Bonhomme assures us that even a lixium of wood ashes, such as is used for washing fine linen, may answer the purpose extremely well.

For a fuller account of this interesting memoir our readers are referred to the 17th volume of the *Annales de Chimie*, or to the first volume of *Nicholson's Philosophical Journal*.

RAJA, the *ray fish*. See *Encyclopædia*, where it is said that the *oxyrinchus* or sharp nosed ray, is supposed to be the *bos* of the ancients; but if there be any truth in the following narrative, which we confess has much the air of fiction, this is probably a mistake. It is the narrative of Vaillant, and we shall give it in his own words.

"In the latitude 10° 15′ north, and longitude 355, an enormous flat fish of the ray genus (says he), came and swam round our vessel. It differed from the common ray, however, in the shape of its head, which, instead of being pointed, formed a crescent, and from the extremities of the semicircle issued two arms as it were, which the sailors called horns. They were two feet wide at the base, and only five inches at the extremity. This monster they told me was called the *sea-devil*.

"A few hours after, we saw two others with this, one of which was so extremely large, that it was computed by the crew to be *fifty* or *sixty* feet wide. Each swam separately, and was surrounded by those small fish which usually precede the shark, and which are therefore called by seamen *pilot-fish*. Lastly, all three carried on each of their horns a white fish, about the size of a man's arm, and half a yard long, which appeared to be stationed there on duty.

"You would have said they were two sentinels placed to keep watch for the safety of the animal, to inform him of any approaching danger, and to guide his movements. If he approached too near the vessel, they quitted their posts, and, swimming briskly before, led him

him away. If he rose too high above the water, they passed backward and forward over his back till he had descended deeper. If, on the contrary, he swam too low, they disappeared, and we saw no more of them, because, no doubt, they were passing underneath, as in the preceding instance they had passed above him. Accordingly we found him reascend towards the surface, and then the two sentinels reassumed their posts, each on his horn."

These manœuvres continued three days; and to give our author the better opportunity of observing them, the ship most fortunately was becalmed the whole time. He was naturally very desirous of catching one of them that he might examine it at leisure; and, by bribing the seamen with a dozen of bottles of wine, he accomplished his object. One of the fish was struck with twelve or fifteen harpoons; several halsers were passed round his body, and he was hoisted on board.

"This (says our author) was the least of the three, being only *eight-and-twenty* feet in its extreme breadth, and *one-and-twenty* in length from the extremity of the horns to that of the tail. The tail, which was thick in proportion to the body, was *twenty-two inches* long. The mouth, placed exactly like that of the ray, was wide enough to swallow a man with ease. The skin was white under the belly, and brown on the back, like that of the ray. We reckoned the animal to weigh not less, certainly, than a ton."

We think it was fortunate that they chanced to strike the smallest fish; for an addition of eight or ten ton weight, which the largest ray must have weighed, as certainly as the smallest weighed one ton, might have been very inconvenient on board a ship already loaded. We do not remember to have anywhere met with a description of this ray before, and we think it should be considered as a new species; but we shall not give it a name till its existence be better ascertained, when we submit to the pupils of Linnæus, whether it may not be proper to give it the ancient name *bos*.

RAJAH. (See *Encyclopædia*.) We learn from Sir Charles Rouse Boughton's *Dissertation concerning the Landed Property of Bengal*, that this title is conferred upon Hindoos by the emperor, and frequently given out of courtesy to the greater zemindars. It would appear therefore that the Rajahs can never be independent of the Mogul but by a successful rebellion.

RAYEL-UL-MULK, in the language of Bengal, the usage of the country, the common law.

RATIO (See *Encyclopædia*) has been defined by Euclid, in the 5th book of his Elements, in terms to which many mathematicians have objected; and his definition of proportion, which is so ultimately connected with it, is still more objectionable. The Rev. Abraham Robertson of Oxford, in a small tract published in 1789, demonstrates the truth of the two definitions in question in seven propositions, of which the substance is as follows He first lays down these four definitions:

"1. Ratio is the relation which one magnitude has to another, of the same kind, with respect to quantity.

"2 If the first of four magnitudes be exactly as great when compared to the second, as the third is when compared to the fourth, the first is said to have to the second the same ratio that the third has to the fourth.

3. If the first of four magnitudes be greater, when compared to the second, than the third is when compared to the fourth, the first is said to have to the second a greater ratio than the third has to the fourth.

"4. If the first of four magnitudes be less, when compared to the second, than the third is when compared to the fourth, the first is said to have to the second a less ratio than the third has to the fourth."

He then demonstrates, by reasoning strictly geometrical, the following propositions:

Prop. 1. If the first of four magnitudes have to the second, the same ratio which the third has to the fourth; then, if the first be equal to the second, the third is equal to the fourth; if greater, greater; if less, less.

Prop. 2. If the first of four magnitudes be to the second as the third to the fourth, and if any equimultiples whatever of the first and third be taken, and also any equimultiples of the second and fourth; the multiple of the first will be to the multiple of the second as the multiple of the third to the multiple of the fourth.

Prop. 3. If the first of four magnitudes be to the second as the third to the fourth, and if any like aliquot parts whatever be taken of the first and third, and any like aliquot parts whatever of the second and fourth, the part of the first will be to the part of the second as the part of the third to the part of the fourth.

Prop. 4. If the first of four magnitudes be to the second as the third to the fourth, and if any equimultiples whatever be taken of the first and third, and any whatever of the second and fourth; if the multiple of the first be equal to the multiple of the second, the multiple of the third will be equal to the multiple of the fourth; if greater, greater; if less, less.

Prop. 5. If the first of four magnitudes be to the second as the third is to a magnitude less than the fourth, then it is possible to take certain equimultiples of the first and third, and certain equimultiples of the second and fourth, such, that the multiple of the first shall be greater than the multiple of the second, but the multiple of the third not greater than the multiple of the fourth.

Prop. 6. If the first of four magnitudes be to the second as the third is to a magnitude greater than the fourth, then certain equimultiples can be taken of the first and third, and certain equimultiples of the second and fourth, such, that the multiple of the first shall be less than the multiple of the second, but the multiple of the third not less than the multiple of the fourth.

Prop. 7. If any equimultiples whatever be taken of the first and third of four magnitudes, and any equimultiples whatever of the second and fourth; and if when the multiple of the first is less than that of the second, the multiple of the third is also less than that of the fourth; or if when the multiple of the first is equal to that of the second, the multiple of the third is also equal to that of the fourth; or if when the multiple of the first is greater than that of the second, the multiple of the third is also greater than that of the fourth: then, the first of the four magnitudes shall be to the second as the third to the fourth.

RATIONAL, in arithmetic, &c. the quality of numbers, fractions, quantities, &c. when they can be expressed by common numbers; in contradistinction to irrational or surd ones, which cannot be expressed in common numbers.

RAYNAL (William Thomas), commonly called the Abbé Raynal, was educated among the Jesuits, and had become one of the order. The learning of that Society is universally

Raynal univerſally known, as well as the happy talents which its ſuperiors poſſeſſed, of aſſigning to each member his proper employment. Raynal, however, after having acquired among them a taſte for literature and ſcience, had probably become refractory, for he was expelled from the order; and the cauſe of his expulſion, according to the Abbé Barruel, was his impiety.

With the real cauſe of his expulſion M. Barruel is ſurely much better acquainted than we can pretend to be; but we have a ſtrong ſuſpicion that his impieties had not then reached farther than to call in queſtion the ſupreme authority of the church; for our author himſelf aſſures us, that he did not utter his atrocious declarations againſt Chriſtianity till he had ceaſed to be a member of the order of Jeſuits. He then aſſociated himſelf with Voltaire, D'Alembert, and Diderot, and was by them employed to furniſh the theological articles for the *Encyclopedie*. But though his religious opinions were certainly lax, and his moral principles very exceptionable, he could not even then be what, in a Proteſtant country, would be deemed a man remarkable for impiety; for he employed the Abbé Yvon, whom M. Barruel calls an odd metaphyſician, but an inoffenſive and upright man, to write the articles which he was engaged to furniſh. In the conducting of this tranſaction, he ſhewed, indeed, that he poſſeſſed not a proper ſenſe of honour; for he paid poor Yvon with twenty-five louis d'ors for writing theological articles, for which he received himſelf ſix times that ſum. This trick was diſcovered, Raynal was diſgraced, and compelled to pay up the balance to Abbé Yvon; but tho' he had thus ſhewn himſelf to be without honour, it is difficult to believe that he had yet proceeded ſo far as to blaſpheme Chriſt, ſince he had employed a Chriſtian divine to ſupply his place in the *Encyclopédie*.

His firſt work of eminence, and that indeed upon which his fame is chiefly built, is his "Political and Philoſophical Hiſtory of the European Settlements in the Eaſt and Weſt Indies." That this hiſtory is written in an animated ſtyle, and that it contains many juſt reflections, both political and philoſophical, is known to all Europe; for it has been tranſlated into every European language. Its beauties, however, are deformed by many ſentiments that are irreligious, and by ſome that are impure. It was followed, we think, in 1780, by a ſmall tract entitled "The Revolution of America;" in which the author pleads the cauſe of the revolted coloniſts with a degree of zeal, cenſures the conduct of the Britiſh government with a keenneſs of aſperity, and diſplays a knowledge of the principles and intrigues of the different factions which at that period divided the Engliſh nation, that ſurely was not natural to the impartial pen of a philoſophic foreigner. Hence he has been ſuppoſed to have been incited to the undertaking, and to have been furniſhed with part of his materials, by that deſperate faction which uniformly oppoſed the meaſures of Lord North, and ſecretly fomented the rebellion in America. Be this as it may, he propagated, both in this tract and in his hiſtory, a number of licentious opinions reſpecting government and religion, of which he lived to regret the conſequences.

A proſecution was inſtituted againſt him by the French government on account of his hiſtory of the Eaſt and Weſt Indies; but it was conducted with ſo little ſeverity, that he had ſufficient time to retire to the dominions of the King of Pruſſia, who afforded him the protection he Raynal ſolicited, although his Majeſty's character was treated by the author in his book with no great degree of veneration. Raynal alſo experienced the kindneſs of the Empreſs of Ruſſia; and it is not a little remarkable of this ſingular perſonage, that, although he was always ſevere in diſcuſſing the characters of princes, yet the moſt deſpotic among theſe heaped upon him many marks of favour and generoſity. The Abbé alſo received a very unuſual mark of reſpect from a Britiſh Houſe of Commons. It was once intimated to the ſpeaker that Raynal was a ſpectator in the gallery. The buſineſs was immediately ſuſpended, and the ſtranger conducted to a more convenient and honourable ſituation. How different was the conduct of Dr Johnſon, who, when a friend advanced to him with our author, ſaying, "Will you give me leave, Doctor, to introduce to you the Abbe Raynal?" turned on his heel, and vociferated, "No, Sir!" We are far from wiſhing to vindicate the rudeneſs of the ſage; but it was perhaps as proper as the politeneſs of the Houſe of Commons.

The great trait of Raynal's character was a love of liberty, which, in his earlier writings, he did not properly define; but when he lived to ſee ſome of the conſequences of this, in the progreſs of the French Revolution, he made one glorious effort to retrieve his errors. In the month of May 1791, he addreſſed to the conſtituent aſſembly one of the moſt eloquent, argumentative, and impreſſive letters that ever was written on any ſubject; a letter which, if the majority of them had not been intoxicated with their newly acquired conſequence, muſt have given ſome check to their mad career. After complimenting them upon what they had done, he proceeds thus: "I have long dared to ſpeak to kings of their duty; ſuffer me now to ſpeak to the people of their errors, and to their repreſentatives of the dangers which threaten us. I am, I own to you, deeply afflicted at the crimes which plunge this empire into mourning. Is it true that I am to look back with horror at myſelf for being one of thoſe who, by feeling a noble indignation againſt arbitrary power, may perhaps have furniſhed arms to licentiouſneſs? Do then religion, the laws, the royal authority, and public order, demand back from philoſophy and reaſon the ties which united them to the grand ſociety of the French nation, as if, by expoſing abuſes, and teaching the rights of the people and the duties of princes, our criminal efforts had broken thoſe ties? But, no!—never have the bold conceptions of philoſophy been repreſented by us as the ſtrict rule for acts of legiſlation.

"You cannot juſtly attribute to us what could only be the reſult of a falſe interpretation of our principles. Alas! now that I ſtand on the brink of the grave; now that I am about to quit this immenſe family, whoſe happineſs I have ardently deſired, what do I ſee around me? Religious troubles, civil diſſenſions, conſternation on the one hand, tyranny and audacity on the other; a government the ſlave of popular tyranny; the ſanctuary of the laws ſurrounded by unruly men, who alternately dictate or deſpiſe thoſe laws; ſoldiers without diſcipline; leaders without authority; miniſters without means; a king, the firſt friend of his people, plunged into bitterneſs, inſulted, menaced, ſtripped of all authority; and the public power no longer exiſting but

in clubs, in which ignorant and rude men dare to decide all political questions."

He then proceeds to prove, which he does very completely, that it was not the business of the assembly to abolish every ancient institution; that the genius of the French people is such, that they never can be happy or prosperous but under a well regulated monarchical government; and that, if they wished not the nation to fall under the worst kind of despotism—the despotism of a low faction, they must increase the power of the king. "Alas! (continues he) what are my sufferings, when in the heart of the capital, in the centre of knowledge, I see this misguided people welcome, with a ferocious joy, the most criminal propositions, smile at the recital of murder, and celebrate their crimes as conquests!"

He had then seen comparatively but little; but he lived to see more—to see his countrymen celebrate, as virtues, crimes, compared with which the atrocities of 1791 appear almost as harmless. Being stripped of all his property, which was large, by the robbers of the revolution, he died in poverty in March 1796, and in the 84th year of his age.

Besides the works which we have already mentioned, he wrote "A History of the Parliament of England," and a "History of the Stadholderate;" but these are both of them more remarkable for a specious style and loftiness of invention than for useful observation or solid argument. He wrote likewise "The History of the Divorce of Catharine of Arragon by Henry the Eighth," which is not so much a recital of, and commentary upon, the fact from which he takes the title, as it is an able picture of universal Europe at that period, of the views, interests, and power, of all the different potentates. At the time of his death he was preparing a new edition of all his works, in which were to be made many alterations; and he is said to have left among his manuscripts a "History of the Revocation of the Edict of Nantes," in four volumes; but it is also very certain, that, during the sanguinary reign of Robespierre, he burnt a great part of his papers.

REAPING, the well known operation of cutting corn either by the sickle or by the scythe. Reaping by the sickle is by much the most common practice, and that which, we believe, prevails universally in Scotland; yet the other method, where it is practicable, is certainly the least laborious, and by much the most expeditious. To the scythe, as an instrument of reaping, many objections are urged.

It is said that it shakes the ear, so that many of the grains are lost; that it lets the corn fall, after cutting it, in a confused and scattered state, so that either much of it is lost, or a great deal of time is consumed in gathering it together; that it can only be made use of in land which is very even and free from stones; that it does not leave sufficient length of stubble in the ground to lay the corn on when cut; that it mixes bad weeds with the corn, the seeds of which are sown the next year; and, lastly, that the use of the scythe is prejudicial to the health of the reaper.

These objections, however, are either of no weight, or they are made by those who are not acquainted with the scythes which have been adapted to this purpose, and with the proper manner of using them. With a good scythe, properly managed, the corn, after being cut, remains at first upright, and then falls very gently upon the rake fixed to the scythe, without any shake or jolt; or at least with less than that which it receives when reaped with a sickle. With respect to the loss of grain, that proceeds chiefly from the corn being too dry; consequently it should be reaped only upon proper days, and proper times of the day, which is much more easily done with the scythe than with the sickle, because the work is so much shorter. The stalks, kept together by the rake, may be laid upon the ground, or rather against the corn not yet cut, in so regular and collected a state, that those who gather and tie the sheaves, whether they are women or children, have nothing but their own negligence to accuse if any thing is left behind. When land is properly ploughed and harrowed, it is sufficiently even; and in such as is stony, the only precaution necessary is to keep the scythe a little higher in using it, that it may not strike against the stones. If the stubble left in the ground be short, the straw which is cut off will be the longer; and the latter is certainly of more value than the former, which only serves to incommode the cattle which afterwards go to feed in the field.

These considerations, and others of a like nature, induced the patriotic society of Milan to send, some years ago, to those parts in which scythes are made use of for reaping; and having procured a model of a scythe from Silesia, they caused one to be made of a proper size. It was first tried upon corn, and afterwards upon millet; and although the first scythe was not accurately made, and the reaper had never before made use of such an instrument, yet it was found that nearly half the usual time was saved, and that the labour and fatigue were much diminished; the corn also was cut without receiving any shock that could be hurtful to it, and fell in an even and regular state, so that it was afterwards easily bound up in compact sheaves. They were afterwards presented with a scythe somewhat different from the Silesian, which is very generally used in Austria.

These instruments are so simple, that the figure of one of them renders the description of either almost unnecessary. In fig. 1. is shewn the Silesian scythe tried by the Society; the difference between that and the Austrian one we shall mention in our description. The first, or Silesian scythe, differs very little from the scythe we commonly use for mowing grass, except that the blade is rather smaller; to it are added four teeth of wood, parallel to the blade, fixed and secured in a proper manner, and intended to keep the corn together after being cut, so that instead of its falling in a confused state, the reaper may lay it down in a regular and compact one. The second, or Austrian scythe, is similar to the former, except that the blade is larger; consequently the wooden teeth, of which there are five, are longer; the handle also is more flat, and rather crooked.

Plate XLII.

In the *first*, the handle *a b* (see fig. 1.) is two Milanese brasses (A), and nine inches and a half in length; the

(A) One hundred Milanese *brasses* are equal to fifty-eight English yards and a half.

Reaping-Rectification.

the blade $b c$ is one brass three inches and a half; the piece of wood in which the teeth are fixed, one brass one inch and a half. In the *second*, the handle is two brasses, and seven inches long; the blade, one brass eleven inches; the piece in which the teeth are fixed, eleven inches and a quarter. The proportions of the other parts may be conceived from the figure.

The difference in the construction of these two scythes makes it requisite to use them in a different manner; but that will be better acquired in practice than by precept. Such of our countrymen as are accustomed to the use of the common scythe will very soon find out the most convenient and advantageous manner of using these new kinds of scythe, and of laying down the corn properly when cut.

It should, however, be observed, that in mowing grass the feet are kept almost parallel to each other, whereas in reaping corn they should be kept upon a line, one behind the other, thrusting the right foot forward, and drawing the left towards it. This is necessary, because when grass is mowed it is left to fall just where it is cut; but when corn is cut, it is to be carried and laid in a proper manner against that which is not yet cut, and which is at the left band of the reaper; and if the feet were kept parallel to each other, the reaper would be obliged to extend and turn his body in a very inconvenient manner.

After having made public these observations, the society made farther experiments upon the subject, in which it was found, that when, on account of very wet weather, the stalks of the corn are bent down, the wooden teeth of the forementioned scythes are apt to lay hold of some ears, to the stalks of which the iron does not reach; and consequently not being cut below, they are pulled so that the grain is scattered. This happens chiefly when the reapers, not being yet sufficiently accustomed to that kind of scythe, do not know how to adapt it to particular circumstances.

To remedy this inconvenience, it occurred to an ingenious blacksmith to add to the common scythe a *gatherer* or *collector* made of cloth, as may be seen at fig. 2. where $a b c$ is a common scythe; [illegible] is the gatherer; which at $c d e$ is composed of a thin plate of iron, having at its extremity a hollow for receiving the point of the blade. At $e d$ are holes for sewing in the cloth, which is coarse, light, and of low price; it is also fixed to two thick iron wires, of which the upper one is continued to f, where it terminates in a hole in the handle; the other is fixed to the back of the blade. The manner of fixing this gatherer to the blade of the scythe will be better understood by referring to fig. 3. which represents one of the irons which, by means of a screw, are fastened to the back of the scythe. These irons proceed from, and make part of, the upright irons $m n$, $l o$, which serve to keep the gatherer extended.

This is a very simple and cheap contrivance; but an attempt was made to render it still more simple, by substituting for the gatherer two iron hoops, which are shown in fig. 2. by the dotted lines $h g$, $k i$, with a cross piece p which connects them. Experience, however, has shewn, that the gatherer is in general preferable to these hoops, as it does not leave an ear of corn behind.

RECTIFICATION OF ETHER, a process for depriving ether of its sulphureous acid (See CHEMISTRY, *Index* in this *Suppl.*) It has been usual to add an alkali for this purpose; but Dizé has found it much more advantageous to add a substance which might afford the requisite quantity of oxygen to convert the sulphureous into the sulphuric acid; in which state it is not disposed to rise and come over. Various metallic oxyds were tried, among which the black oxyd of manganese proved the best and the cheapest. His process is as follows:

Rectification, Turkey Red.

The sulphureous acid contained in unrectified ether being neutralized with oxyd of manganese, the fluid is decanted into a pewter vessel of the capacity of fifty ounces, which is placed on a water bath. To this vessel a head and worm are adapted, the latter of which passes through a refrigeratory constantly supplied with water in a stream from below, which causes the heated water to flow off above. The distillation is then performed by raising the bath to a temperature of [illegible] (113° Fahrenheit, if the decimal thermometer be here meant). The rectification by this treatment [illegible] requires a day to complete it. The flavour of the ether is of the best kind, and the product about one sixth more than in the usual method with retort and receiver. Dizé has practised this method with success for three years.—*Journal de Physique, April*, 179[illegible].

RECTIFICATION, in geometry, is the finding of a right line equal to a curve. The rectification of curves is a branch of the higher geometry, a branch in which the use of the inverse method of fluxions is especially useful.

TURKEY-RED, *Levant-Red*, and *Adrianople-Red*, the names indifferently given to that beautiful [illegible] which distinguishes the cotton manufactured in the Ottoman empire, and at *Astracan* in the dominions of Russia. We have two accounts of the process of communicating this dye to the stuffs; one by Professor Pallas as he saw it practised at Astracan; the other in the 92d number of the *Annales de Chimie* by Citizen Felix. As every thing relating to useful manufactures is of general importance, we shall give pretty copious extracts from both papers.

According to Dr Pallas, the dye stuffs employed at Astracan are, madder, sumach, gall-nuts, alum, an inferior kind of soda, and fish-oil. The process of dyeing is as follows:

The roots of the madder, when fresh gathered, are placed above each other in a stove, or in a pit dug in viscous earth which has been strongly heated. Earth is then thrown over the madder, and it must sweat until the stove or pit becomes cold; when the roots, the second or third day, are taken from it, and either spread out or hung up to dry. When it is thoroughly dried in the sun, the madder is ground to a very fine powder, as are likewise the round leaves of the sumach (*rhus cotinus*). The fish-oil is boiled from the entrails of the sturgeon and other large fishes; and the proof of its being proper for dyeing is, that when mixed with a lixivium of soda, it must immediately assume a milky appearance. Should that not be the case, it cannot be used by the dyers.

The cotton to be dyed red is first washed exceedingly clean in running water; and when the weather is clear, hung up on poles to dry. If it does not dry before the evening, it is taken into the house, on account of

Turkey-Red.

of the ſaline dews ſo remarkable in the country around Aſtracan, and again expoſed to the air next morning. When it is thoroughly dry it is laid in a tub, and fiſh-oil is poured over it till it is entirely covered. In this ſtate it muſt ſtand all night; but in the morning it is hung up on poles, and left there the whole day; and this proceſs is repeated for a week, ſo that the cotton lies ſeven nights in oil, and is expoſed ſeven days to the atmoſphere, that it may imbibe the oil, and free itſelf from all air. The yarn is then again carried to a ſtream, cleaned as much as poſſible, and hung up on poles to dry.

After this preparation a mordant is made of three materials, which muſt give the grounds of the red colour. The pulverized leaves of the ſumach are firſt boiled in copper kettles; and when their colouring matter has been ſufficiently extracted, ſome powdered galls are added, with which the liquor muſt be again boiled; and by theſe means it acquires a dark dirty colour. After it has been ſufficiently boiled the fire is taken from under the kettle, and alum put into the ſtill hot liquor, where it is ſoon diſſolved. The proportion of theſe three ingredients cannot be aſcertained, as the dyers vary that proportion at pleaſure. The powder of the ſumach leaves is meaſured into the kettle with ladles; the water is poured in according to a gauge, on which marks are made to ſhew how high the water muſt ſtand in the kettle to ſoak ſix, eight, ten, &c. puds of cotton yarn. The galls and alum are added in the quantity of five pounds to each pud of cotton. In a word, the whole mordant muſt be ſufficiently yellow, ſtrong, and of an aſtringent taſte.

As ſoon as the alum is diſſolved, no time muſt be loſt in order that the mordant may not be ſuffered to cool. The yarn is then put into hollow blocks of wood ſhaped like a mortar, into each of which ſuch a quantity of the mordant has been poured as may be ſufficient to moiſten the yarn without any of it being left. As ſoon as the workman throws the mordant into the mortar, he puts a quantity of the yarn into it, and preſſes it down with his hand till it becomes uniformly moiſtened, and the whole cotton yarn has ſtruck. By this it acquires only a pale yellow colour, which, however, is durable. It is then hung up on poles in the ſun to dry; again waſhed in the ſtream, and afterwards dried once more.

The next part of the proceſs is to prepare the madder dye. The madder, ground to a fine powder, is ſpread out in large troughs, and into each trough is poured a large cupful of ſheep's blood, which is the kind that can be procured with the greateſt facility by the dyers. The madder muſt be ſtrongly mixed in it by means of the hand, and then ſtand ſome hours in order to be thoroughly ſoaked by it. The liquor then aſſumes a dark red appearance, and the madder in boiling yields more dye.

After this proceſs water is made hot in large kettles, fixed in brickwork; and as ſoon as it is warm, the prepared red dye is put into it, in the proportion of a pound to every pound of cotton. The dye is then ſuffered to boil ſtrongly; and when it is enough, which may be tried on cotton threads, the fire is removed from under the kettle, and the prepared cotton is depoſited near it. The dyer places himſelf on the edge of the brickwork that incloſes the kettle; dips the cotton yarn, piece by piece, into the dye; turns it round backwards and forwards; preſſes it a little with his hands; and lays each piece, one after the other, in pails ſtanding ready for the purpoſe. As ſoon as all the cotton has received the firſt tint, it is hung up to dry; as the red, however, is ſtill too dull, the yarn, which has been already dyed once, and become dry, is put once more into the dyeing-kettle, and muſt be left there to ſeethe for three hours over a ſtrong fire; by which it acquires that beautiful dark red colour which is ſo much eſteemed in the Turkey yarn. The yarn is now taken from the dye with ſticks; the ſuperfluous dye which adheres to it is ſhaken off; the hanks are put in order, and hung up, one after another, to dry. When it is thoroughly dry, it is waſhed in the pure ſtream, and again dried.

Turkey-Red.

In the laſt place, the above mentioned ſoda is diſſolved with boiling water in tubs deſtined for that purpoſe, and it is uſual at Aſtracan to allow 20 pounds of ſoda to 40 pounds of cotton, or half the weight. Large earthen jars, which are made in Perſia of very ſtrong clay, a yard and a half in height, almoſt five ſpans wide in the belly, and ending in a neck a ſpan and a half in diameter, incloſed by means of cement in brickwork over a fire-place, in ſuch a manner that the necks only appear, are filled with the dyed cotton yarn. The ley of diſſolved ſoda, which is blackiſh and very ſharp, is then poured over it till the jars be filled; and ſome clean rags are preſſed into their mouths, that the uppermoſt ſkains of yarn may not lie uncovered. A fire is then made in the fire place below, and continued for 24 hours; and in the mean time the ſteam which ariſes from the jars is ſeen collected among the rags in red drops. By this boiling the dye is ſtill more heightened, and is made to ſtrike completely; every thing ſuperfluous is removed, and all the fat matter which ſtill adheres to the yarn is waſhed out. Nothing more is then neceſſary for completing the dye of the yarn but to rinſe it well ſeveral times in running water, and then to dry it.

Cotton cloth is dyed with madder at Aſtracan in the ſame manner; but many purſue a fraudulent proceſs, by dying with red wood, and then ſell their cloth as that which has been dyed in the proper manner.

The proceſſes followed in the Grecian manufactories in the Levant, as deſcribed by M. Felix, varies in ſome particulars from this. The firſt proceſs is that of cleaning the cotton: for which purpoſe three leys are employed; one of ſoda, another of aſhes, and a third of lime. The cotton is thrown into a tub, and moiſtened with the liquor of the three leys in equal quantities: it is then boiled in pure water, and waſhed in running water.

The ſecond bath given to the cotton is compoſed of ſoda and ſheep's dung diſſolved in water. To facilitate the ſolution, the ſoda and dung are pounded in a mortar. The proportions of theſe ingredients employed, are one occa of dung, ſix of ſoda, and forty of water; each occa being equal to about fifty ounces. When the ingredients are well mixed, the liquor expreſſed from them is ſtrained; and being poured into a tub, ſix occas of olive oil are added to it, and the whole is well ſtirred till it becomes of a whitiſh colour like milk. The cotton is then beſprinkled with this water; and when the ſkains are thoroughly moiſtened, they are wrung,

wrung, preſſed, and expoſed to dry. The ſame bath muſt be repeated three or four times, becauſe it is this liquor which renders the cotton more or leſs fit for receiving the dye. Each bath is given with the ſame liquor, and ought to continue five or ſix hours. It is to be obſerved that the cotton, after each bath, muſt be dried without being waſhed, as it ought not to be rinſed till after the laſt bath. The cotton is then as white as if it had been bleached in the fields.

It may be ſuppoſed that the dung is of no utility for fixing the colours: but this ſuppoſition would be raſh; for, as M. Felix obſerves, it is well known that this ſubſtance contains a great quantity of volatile alkali in a diſengaged ſtate, which has the property of giving a roſy hue to the red. It is therefore probable that it is to this ingredient that the red dyes of the Levant are indebted for their ſplendour and vivacity. This much, at any rate, is certain, that the Morocco leather of the Levant is prepared with dog's dung; becauſe it has been found that this dung is proper for heightening the colour of the lack.

The proceſs of galling, which follows the bath of dung, is performed by immerſing the cotton in a bath of warm water, in which five occas of pulveriſed gall-nuts have been boiled. This operation renders the cotton more fit for being ſaturated with the colour, and gives to the dye more body and ſtrength. After the galling comes aluming, which is performed twice, with an interval of two days, and which conſiſts in dipping the cotton into a bath of water in which five occas of alum have been infuſed, mixed with five occas of water alkaliſed by a ley of ſoda. The aluming muſt be performed with care, as it is this operation which makes the colouring particles combine beſt with the cotton, and which ſecures them in part from the deſtructive action of the air. When the ſecond aluming is finiſhed, the cotton is wrung; it is then preſſed, and put to ſoak in running water, after being incloſed in a bag of thin cloth.

The workmen then proceed to the dyeing. To compoſe the colours, they put in a kettle five occas of water, and 25 occas of a root which the Greeks call *ali-zari*, or painting colour, and which in Europe is known under the name of *madder*. The madder, after being pulveriſed, is moiſtened with one occa of ox or ſheep's blood. The blood ſtrengthens the colour, and the doſe is increaſed or leſſened according to the ſhade of colour required. An equal heat is maintained below the kettle, but not too violent; and when the liquor ferments, and begins to grow warm, the ſkains are then gradually immerſed before the liquor becomes too hot. They are then tied with packthread to ſmall rods placed croſſwiſe above the kettle for that purpoſe; and when the liquor boils well, and in an uniform manner, the rods from which the ſkains were ſuſpended are removed, and the cotton is ſuffered to fall into the kettle, where it muſt remain till two-thirds of the water is evaporated. When one third only of the liquor remains, the cotton is taken out and waſhed in pure water.

The dye is afterwards brought to perfection by means of a bath alkaliſed with ſoda. This manipulation is the moſt difficult and the moſt delicate of the whole, becauſe it is that which gives the colour its tone. The cotton is thrown into this new bath, and made to boil over a ſteady fire till the colour aſſumes the required tint. The whole art conſiſts in catching the proper degree: a careful workman, therefore, muſt watch with the utmoſt attention for the moment when it is neceſſary to take out the cotton; and he will rather burn his hand than miſs that opportunity. Turkey-Red || Reflector.

It appears that this bath, which the Greeks think of ſo much importance, might be ſupplied by a ley of ſoap; and it is probable that ſaponaceous water would give the colour more brightneſs and purity.

M. Felix ſeems doubtful whether the ali-zari of the Greeks be the ſame plant with the European madder. If it be, its ſuperiority muſt ariſe from the mode in which it is cultivated, and the method employed to dry it. The ali-zari is not collected till the fifth or ſixth year of its growth, when it has acquired its full ſtrength; and as it is the woody part of the roots which affords the greateſt quantity of colouring particles, this muſt give it an obvious ſuperiority over madder, which is collected before it has arrived at maturity. The mode of deſiccation contributes alſo, in the opinion of our author, to improve the quality of the ali-zari. The Levantines dry it in the open air; and this operation is eaſy in a country where great dryneſs prevails in the atmoſphere, while in our damp climates we are obliged to dry the madder by ſtoves. Hence it happens that the ſmoke, which mixes itſelf with the cold air, and penetrates the roots, impregnates them with fuliginous particles, which alter the colouring ſubſtance; an accident which does not take place when the madder is dried without the aſſiſtance of fire.

For the philoſophical principles of theſe proceſſes of dyeing, ſee *Animal and Vegetable Substances* in this *Supplement*.

REDINTEGRATION, is the taking or finding the integral or fluent again from the fluxion. See Fluxions, *Encycl.*

REFLECTOR for a light-house, is compoſed of a number of ſquare plane glaſs mirrors, ſimilar to thoſe with which Archimedes is ſaid to have ſet fire to the Roman fleet at the ſiege of Syracuſe (See Burning, *Encycl.*) Each of theſe mirrors is about an inch ſquare; and they are all diſpoſed cloſe to each other in the concave of a parabolic ſegment, formed of ſtucco or any other proper bed. Stucco has been found to anſwer the purpoſe beſt; and is accordingly employed in all the reflectors of the light-houſes erected by Mr Thomas Smith tinplate worker, Edinburgh, at the expence, and by the authority, of government. This ingenious and modeſt man ſeems to have conceived the idea of illuminating light-houſes by means of lamps and reflectors inſtead of coal-fires, without knowing that ſomething of the ſame kind had been long uſed in France; he has therefore all the merit of an inventor, and what he invented he has carried to a high degree of perfection.

His parabolic moulds are from three to five or ſix feet in diameter; and in the centre or apex of each is placed a long ſhallow lamp of tin-plate, filled with whale oil. In each lamp are ſix cotton wicks, almoſt contiguous to each other, which are ſo diſpoſed as to burn without trimming for about ſix hours. The light of theſe is reflected from each mirror ſpread over the concave ſurface, and is thus multiplied, as it were, by the number of mirrors. The ſtucco moulding is covered on the back with tin plate, from which a tube, immediately over the lamp, proceeds to the roof of the

 light

light room, and serves as a funnel, through which the smoke escapes without sullying the faces of the mirrors. The light-room is a cupola or lantern of from eight to twelve sides, composed entirely of glass, fixed in cast-iron frames or sashes, and roofed with copper. On circular benches passing round the inside of this lantern, at about eighteen inches from the glass frames, are placed the reflectors with their lamps, so as that the concave surfaces of two or three of the reflectors front every point of the compass, and throw a blaze of light in all directions. In the roof immediately over the centre of the room is a hole, through which pass all the funnels already mentioned, and which serves likewise to admit fresh air to the lamps. This light-room is firmly fixed on the top of a round tower so as to be immoveable by the weather; and the number of the reflectors, and the height of the tower, are less or greater according as it is the intention that the light should be seen at a less or a greater distance.

A man judging from mere theory would be very apt to condemn light-houses of this kind; because the firmest building shakes in a violent storm, and because such shaking, he might think, would sometimes throw the whole rays of light into the air, and thus mislead the bewildered seaman. This opinion, we know, was actually entertained of them by one of the profoundest philosophers and most scientific mechanicians of the age. Experience, however, has convinced him, as well as the public at large, that such apprehensions are groundless, and that light-houses with lamps and reflectors are, in every point of view, preferable to those with fires burning in the open air. They are supported at much less expence; their light is more brilliant, and seen at a greater distance, whilst it can never be obscured by

r beaten down on the lee side by a violent gust and what is perhaps of still greater importance, the reflectors with their lamps may be so variously placed, that, as Mr Smith observes, one light-house cannot be mistaken for another. If we add to all this, that the lamps do not stand in need of trimming so often as open fires require fuel, and that the light man is never exposed either to cold or to wet by attending to his duty, we must be convinced that light-houses with reflectors are much less liable to be neglected in stormy weather than those with open fires, and that this circumstance alone would be enough to give the former a preference, almost incalculable, over the latter.

It has been proposed to make the concave surface of the parabola one speculum of metal, instead of covering it over with a multitude of plain glass mirrors; or to diminish the size of each mirror, if they are to be retained in preference to the metallic speculum. To every man who has but dipped into the science of optics, it must be obvious, that either of these alterations would be wrong. The brightest metal does not reflect such a quantity of light as well foliated clear glass; and were the size of the mirrors to be diminished, the number of joinings would be increased, in each of which some light is lost, not merely in the seam, but from its being almost impossible to foliate glass perfectly at its edge.

REFLEXITY, a word employed by Mr Brougham to denote a property of light which causes the different rays to be acted upon by bodies, and to begin to be refracted, reflected, inflected, and deflected, at different distances. This property follows the same law that the other optical properties of light follow: the red ray having most reflexity, and the violet least (See *Philosophical Transactions*, 1797, p. 360.) Mr Brougham has denoted this property by the three words, *refrangity*, *reflexity*, and *flexity*; but as the power is the same, there is no occasion for different names. Some philosophers have refused to admit this as a new property; we have not verified it by experiment.

REFRACTION OF ALTITUDE, is the arc or portion of a vertical circle, by which the altitude of a star is increased by the refraction of light.

Refraction of Ascension and Descension, is an arc of the equator, by which the ascension and descension of a star, whether right or oblique, is increased or diminished by the refraction.

Refraction of Declination, is an arc of a circle of declination, by which the declination of a star is increased or diminished by refraction.

Refraction of Latitude, is an arc of a circle of latitude, by which the latitude of a star is increased or diminished by the refraction.

Refraction of Longitude, is an arc of the ecliptic, by which the longitude of a star is increased or diminished by means of the refraction.

Terrestrial Refraction, is that by which terrestrial objects appear to be raised higher than they really are, in observing their altitudes. The quantity of this refraction is estimated by Dr Maskelyne at one tenth; by Le Gendre at one fourteenth; by De Lambre at one-eleventh; and by others at a twelfth of the distance of the object observed, expressed in degrees of a great circle. But it is obvious that there can be no fixed quantity of this refraction, since it depends upon the state of the atmosphere, which is extremely variable. Hence some very singular effects of it are relat which the following is worthy of notice. It is from the Philosophical Transactions of London, being an extract of a letter, dated Hastings, August 1797.

"On Wednesday, July 26, about five o'clock in the afternoon, while I was sitting in my dining room at this place, which is situated upon the Parade, close to the sea shore, nearly fronting the south, my attention was excited by a number of people running down to the sea-side. Upon enquiring the reason, I was informed that the coast of France was plainly to be distinguished by the naked eye. I immediately went down to the shore, and was surprised to find that, even without the assistance of a telescope, I could very plainly see the cliffs on the opposite coast; which, at the nearest part, are between 40 and 50 miles distant, and are not to be discerned, from that low situation, by the aid of the best glasses. They appeared to be only a few miles off, and seemed to extend for some leagues along the coast. I pursued my walk along the shore eastward, close to the water's edge, conversing with the sailors and fishermen upon the subject. They at first could not be persuaded of the reality of the appearance; but they soon became so thoroughly convinced, by the cliffs gradually appearing more elevated, and approaching nearer, as it were, that they pointed out and named to me the different places they had been accustomed to visit; such as the Bay, the Old Head or Man, the Windmill, &c. at Boulogne; St Vallery, and other places on the coast of Picardy; which they afterwards confirmed when they

Regis || Regulus.

they viewed them through their teleſcopes. Their obſervations were, that the places appeared as near as if they were ſailing, at a ſmall diſtance, into the harbours."

The writer of this extract was W. Latham, Eſq; F. R. S. and A. S. who adds, that the day was extremely hot, that it was high water at Haſtings about two o'clock P. M. and that not a breath of wind was ſtirring the whole day.

REGIS (Peter Sylvain), a French philoſopher, and great propagator of Carteſianiſm, was born in Agenois 1632. He cultivated the languages and philoſophy under the Jeſuits at Cahors, and afterwards divinity in the univerſity of that town, being deſigned for the church. He made ſo uncommon a progreſs, that at the end of four years he was offered a doctor's degree without the uſual charges; but he did not think it became him to accept of it till he had ſtudied alſo in the Sorbonne at Paris He went thither, but was ſoon diſguſted with theology: and as the philoſophy of Des Cartes began at that time to make a noiſe through the lectures of Rohault, he conceived a taſte for it, and gave himſelf up entirely to it. He frequented theſe lectures; and becoming an adept, went to Toulouſe in 1665, and read lectures in it himſelf. Having fine parts, a clear and fluent manner, and a happy way of making himſelf underſtood, he drew all ſorts of people; the magiſtrates, the learned, the eccleſiaſtics, and the very women, who now all affected to abjure the ancient philoſophy. In 1680 he returned to Paris; where the concourſe about him was ſuch, that the ſticklers for Peripateticiſm began to be alarmed. They applied to the archbiſhop of Paris, who thought it expedient, in the name of the king, to put a ſtop to the lectures; which accordingly were diſcontinued for ſeveral months. The whole life of Regis was ſpent in propagating the new philoſophy. In 1690 he publiſhed a formal ſyſtem of it, containing logic, metaphyſics, phyſics, and morals, in 3 vols 4to, and written in French. It was reprinted the year after at Amſterdam, with the addition of a diſcourſe upon ancient and modern philoſophy. He wrote afterwards ſeveral pieces in defence of his ſyſtem, in which he had diſputes with M. Huet, Du Hamel, Malebranche, and others. His works, though abounding with ingenuity and learning, have been diſregarded, in conſequence of the great diſcoveries and advancement in philoſophic knowledge that have been ſince made. He died in 1707. He had been choſen member of the academy of ſciences in 1699*.

* Biog. Dict. new edit.

REGULAR BODY, called alſo *Platonic Body*, is a body or ſolid comprehended by like, equal, and regular plane figures, and whoſe ſolid angles are all equal.

The plane figures by which the ſolid is contained are the faces of the ſolid; and the ſides of the plane figures are the edges, or linear ſides of the ſolid.

There are only five regular ſolids, viz.

The tetrahedron, or regular triangular pyramid, having four triangular faces;

The hexahedron, or cube, having ſix ſquare faces;

The octahedron, having eight triangular faces;

The dodecahedron, having twelve pentagonal faces;

The icoſahedron, having twenty triangular faces.

Beſides theſe five, there can be no other regular bodies in nature. See PLATONIC *Body*, Suppl.

REGULUS, in aſtronomy, a ſtar of the firſt magnitude, in the conſtellation Leo; called alſo, from its ſituation, *Cor Leonis*, or the *Lion's Heart*: by the Arabs, *Allabor*; and by the Chaldeans, *Kalbeleced*, or *Karbeleced*; from an opinion of its influencing the affairs of the heavens.

Reid.

REID (Thomas, D. D.), ſo well known to the public by his moral and metaphyſical writings, was the ſon of the Rev. Lewis Reid, miniſter of the pariſh of Strachan, in the county of Kincardine, North Britain. His mother was the daughter of David Gregory, Eſq; of Kinardie, of whom ſome account has been given in this *Supplement*, and ſiſter to David, James, and Charles Gregories, who were at the ſame time profeſſors of aſtronomy, or mathematics, in the univerſities of Oxford, Edinburgh, and St Andrews.

He was born at the parſonage houſe of Strachan in April 1710, and received the rudiments of his education at the pariſh ſchool of Kincardine-oniel. At that period the parochial ſchools of Scotland were very ſuperior to what they are now; and young men went from them to the univerſity well furniſhed with philological learning. The progreſs of young Reid muſt have been rapid; for he was removed from ſchool to the Mariſchal College, Aberdeen, when not more than twelve years of age; and we have never heard that he was admitted into the univerſity before he wa to profit by the lectures of the profeſſors. On the trary, he ſoon diſplayed the genius of his mother's family, and ſhone conſpicuous among the ſtudents of mathematics in a college where that ſcience has been at all times cultivated with ardour and ſucceſs.

After the uſual courſe of four years employed in the ſtudy of Latin, Greek, Mathematics, and Philoſophy, he probably took his degree of M. A. which at that period, and for a long time ſubſequent to it, univerſal practice in the univerſity of Aberdeen, and then commenced the ſtudy of theology. In due time he was licenſed to preach the goſpel according to the forms of the church of Scotland; but continued to reſide for ſome years in Aberdeen, cultivating his favourite ſcience, mathematics.

The mathematical chair in Mariſchal College was then filled by Mr John Stuart, a man of great eminence in his profeſſion; but who, like many other profound mathematicians, was not happy in his mode of communicating ſcience, at leaſt to the duller part of his pupils. Mr Reid occaſionally read lectures for the profeſſor; and a friend of our's, by no means dull, has often heard to expreſs great ſatisfaction that Mr Stuart was kept a whole winter from the ſchools, when he ſtudent, and that the claſs was taught by Mr Reid. "Had it not been for this circumſtance (ſaid he) I ſhould never have underſtood more of mathematics than the firſt ſix books of Euclid's elements; but Mr Reid had the faculty of making every thing intelligible to the ſtudents which he clearly apprehended himſelf."

He could not, however, ſpend his life in the ſtudy of mathematics, and in reading barren lectures for other men. He had been educated for the church; and it was in the church only that he had the proſpect of gaining a livelihood. He was accordingly preſented, we know not in what year, to the church of *New Machar* in Aberdeenſhire, at a time when the good people of Scotland were very far from being reconciled to the rights of patronage; and the conſequence was, that

that his settlement met with much popular opposition. Even a little riot took place in the church at his ordination, but he soon gained the affections of his flock by his good sense, his acknowledged worth, and his unwearied attention to all their wants, which he was ever ready to relieve to the utmost extent of his abilities. So deeply rooted indeed was their regard for him at last, that, though it is now almost half a century since his relation to the parish of New Machar ceased, his memory continues to be revered in that parish even at the present day; and the following anecdote evinces that it is not revered without reason.

A man who, from being in decent circumstances, and a member of the kirk session (See PRESBYTERIANS, *Encycl*), when Dr Reid was minister, had become, in his old age, poor and infirm, observed to the then minister of the parish, that if he were able to go to Glasgow, and make his case known to his old friend and pastor, he was sure that he would get something done for him. This observation was reported to the Doctor, who instantly recollected the man, though, in all probability, he had not thought of him for thirty years; and he settled upon him an annual pension of ten pounds, which was punctually paid as long as they both lived. The pride of science had not from the mind of this great man eradicated the amiable sympathies of humanity, nor had his philosophic fame made him overlook the unaspiring duties of the Christian pastor.

In the year 1751, about the beginning of the session or annual term, one of the professors of philosophy in King's College, Aberdeen, died; and his death being unexpected, presented to the other members of that learned body some difficulty in carrying on the usual course of education for that year. At this our readers will not be surprised, when they reflect on the mode in which science was taught in that university; for he who could with propriety be placed in the vacant chair, must have been qualified, without much previous preparation, to read lectures on LOGIC, ONTOLOGY, PNEUMATICS, MORALS, POLITICS, MATHEMATICS, and NATURAL PHILOSOPHY (See GERARD, in this *Suppl.*). In such a place as Aberdeen, it is hardly to be supposed that there was a single man unemployed, so completely master of all these branches of science, as to take up the class where it was dropt by the deceased professor, and carry it successfully through that science, whatever it might be, in which, at his death, he chanced to be lecturing. It occurred, however, to the principal, and some of the professors, that the minister of New Machar was fully equal to the task; and the late Dr John Gregory, then professor of medicine, and the Rev. Dr Macleod, the present subprincipal of King's College, were deputed to visit Mr Reid, and request his immediate acceptance of the vacant professorship. He yielded to the request not without some hesitation, and was admitted professor of philosophy on the 22d of November.

He was now in the very situation for which Nature seemed to have intended him. He had not only an opportunity, but it was his duty to cultivate the science to which his attachment was so strong; and the duties of his office made him turn his attention more closely than he had hitherto done to another science, in which he was destined to make a more conspicuous figure than he ever made even in his favourite mathematics.

It was during his professorship in the university of Aberdeen that he wrote his "Essay on Quantity," which was published in the 45th volume of the Philosophical Transactions, and is perhaps the finest specimen of metaphysical mathematics, if we may use such an expression, that is extant in our own or in any other language (See QUANTITY, *Encycl.*). It was during the same period that he published his "Inquiry into the Human Mind on the Principles of Common Sense;" a work of unquestionable merit, which has contributed more than any other work whatever to give a rational turn to metaphysical speculations. It was about this period that the degree of D. D. was conferred upon him by his mother-college.

The well earned fame of Dr Reid attracted the attention of the university of Glasgow to him as the fittest person to succeed the celebrated Dr Adam Smith; and he was admitted professor of moral philosophy in that university on the 11th of June 1764. There his attention was not distracted by a multitude of sciences, which it was his duty to teach; and he had leisure to improve his metaphysical system, though he continued through life to amuse himself occasionally with mathematical speculations.

In the year 1773 appeared, in Lord Kames's "Sketches of the History of Man, a brief Account of Aristotle's Logic; with remarks by Dr Reid." It would seem that he had entered upon this task rather reluctantly, and merely in compliance with the solicitations of his friend, the author of the Sketches. "In attempting (says he) to give some account of the analytics, and of the topics of Aristotle, ingenuity requires me to confess, that though I have often purposed to read the whole with care, and to understand what is intelligible, yet my courage and patience always failed before I had done. Why should I throw away so much time and painful attention upon a thing of so little use? If I had lived in those ages when the knowledge of Aristotle's Organon intitled a man to the highest rank in philosophy, ambition might have induced me to employ upon it some years of painful study; and less, I conceive, would not be sufficient. Such reflections as these always got the better of my resolution, when the first ardour began to cool. All I can say is, that I have read some parts of the different books with care, some slightly, and some perhaps not at all. I have glanced over the whole often; and when any thing attracted my attention, have dipped into it till my appetite was satisfied."

Notwithstanding this modest acknowledgment, we are not sure that any one of Dr Reid's publications does him greater honour than his very perspicuous view of this stupendous system. Having ourselves occasionally looked into the writings of Aristotle, we should not hesitate to say, that it is by much the best analysis of these writings that we have anywhere met with, even though we could not corroborate our own opinion by that of other men much more conversant than we are with the oracular language of the Stagyrite. But when it is known that the late Dr Doig of Stirling, to whom Greek was as familiar as his mother tongue, and an equally learned Doctor of Oxford, who has been reading Aristotle ever since he was fourteen years of age, agreed in opinion, that a more accurate view of his logic could not be given in the same compass than had been

Reid.

been given by Dr Reid, we may furely affirm, with fome degree of confidence, that this fmall work adds much to the fame of our celebrated countryman.

Though Dr Reid's health continued good, and his mental faculties unimpaired, till a very fhort time before his death, he ceafed for fome years to read lectures from his profefforial chair, employing that time in preparations for eternity, and in fitting his lectures for the prefs. Thefe were publifhed in two volumes 4to: the the firft in 1785, under the title of "Effays on the Intellectual Powers of Man," dedicated to his friends Dr Gregory and Profeffor Stewart, both of the univerfity of Edinburgh; and the fecond in 1788, under the title of "Effays on the Active Powers of Man," without any dedication or preface. He continued to enjoy the fame acquired by this work, as well as the affection of his friends and the reverence of the public, for eight years, dying at Glafgow in the end of September, or the beginning of October 1796, in the 87th year of his age. He had been married, and he left behind him one daughter.

To do juftice to the biography of fuch a man as this, we fhould here attempt to draw his intellectual character, and to appreciate the merits of his works; but to perform this tafk in a manner at all worthy of him, or we hope of ourfelves, would require more room than our limits permit us to allot to any article of the kind; and our readers will be pleafed to learn, that they may confidently expect an account of his life, with a critique on his works, by a man better qualified to do juftice to both, than the writer of this fhort fketch pretends to be. His works are in the hands of the fpeculative public; and by that public will be duly valued, as long as found fenfe fhall be preferred to unpleafing jargon. How long that may be, God only knows; but if any [illegible] to guard the minds of our youth againft that [illegible] of which the object is to attribute real agency [illegible] fluids, and to reprefent the elective attractions of chemiftry as perfectly fimilar to human volitions, it will be the unbiaffed ftudy of Dr Reid's "Effays on the Intellectual and Active Powers of Man." They will there find metaphyfics divefted of myftery, and the profoundeft fpeculations rendered intelligible by the conftant ufe of words in one determined fenfe. We think, indeed, that in this confifts the Doctor's chief merit; for, except when treating of our notions of power, he feems not to have added much to what certainly *may be* found in the writings of Locke.

Let not our readers fuppofe, that by this obfervation we wifh to detract in the fmalleft degree from our author's fame, or to leffen him by comparifon with the Englifh philofopher. If on mere topics of fpeculative fcience, he appears to us to have thought as Locke thought, it is on the other hand certain, that the greater part of Locke's doctrines may be gleaned from the logical and metaphyfical writings of Bacon, Hobbes, and Des Cartes. Nor need this furprife any one; for he who reflects a moment on the fubject, muft perceive that fuch a coincidence of thought in metaphyfical fcience is among men of eminence almoft inevitable. Of mind and its powers—the fubject of that fcience—we neither know, nor can know any thing, but by patiently attending to the operations of our own minds, when we fee, hear, feel, think, reafon, and will, &c.: and it is obvious, that every man who is capable of fuch patient attention, and does not labour under the bias of fome prejudice, muft view thefe operations in the fame way. The great fuperiority of Dr Reid over his predeceffors, in this department of fcience, appears to have been this, that he apprehended the operations of his own mind with a clearnefs, which gave to his language a precifion and perfpicuity which the language of Locke certainly does not poffefs.

In the Effay on the Human Underftanding, the term *idea* fometimes fignifies a material fubftance, fometimes the qualities of that fubftance, fometimes the conception of thefe qualities, fometimes the power or faculty of the mind by which we conceive a thing, fometimes a perception of fenfe, and fometimes an intellectual notion. Hence the ambiguity of terms which runs thro' the whole of that immortal work, has furnifhed both the author's friends and his enemies with an opportunity of attributing to him pernicious doctrines, which we are perfuaded he did not maintain, and which, we think, a patient analyfis of the effay muft *convince every man* that he did not maintain. From this ambiguity the writings of Dr Reid are perfectly free. His doctrines, whether well or ill-founded, can never be mifunderftood by him who is defirous to underftand them; and he who knows how much perfpicuity of ftyle depends upon accuracy of thinking, will not deem us enemies to his fame for having faid that his chief merit confifts in the precifion of his language.

He has been much cenfured by fome, and much applauded by others, for introducing the phrafe *common fenfe* into fpeculative philofophy, as the proper name of that faculty of the mind by which we apprehend firft truths; but he is on this account entitled neither to praife nor to cenfure. He adopted the phrafe from others; and has proved, by the moft unexceptionable authorities, both ancient and modern, that it may with great propriety be ufed as he has ufed it. Whether the adopting of it into works of fcience was neceffary, is another queftion, on which we have given our opinion elfewhere; it is fufficient in this place to vindicate his ufe of it, efpecially in his latter works, from ambiguity.

Candour obliges us to acknowledge, that he has advanced fome doctrines which we cannot admit as true. Though not in general partial to Locke, he has adopted his notions refpecting our power of abftraction, with hardly any other variation than the fubftituting of the term *conceptions* for Locke's favourite phrafe *ideas*. He has likewife endeavoured to prove, that we may diftinctly conceive what cannot poffibly exift. Thefe miftakes, for fuch they appear to us, we have pointed out elfewhere (See Metaphysics, Part I. Chap. iii. and iv. *Encycl.*); but they are infinitely more than counterbalanced by his clear, accurate, and fatisfactory difquifitions on our notions of active power. Had Dr Reid never written a fentence but the effay which treats of this delicate and important fubject, he would have been entitled to a place in the very firft rank of ufeful metaphyficians; for, previous to the appearance of his works, we had nothing written directly on *power* but contradictory and unintelligible jargon. We recommend the ferious perufal of this effay, the firft in his fecond volume, to fuch of our readers as fancy that they diftinctly conceive the powers of chemical agents, and that intelligence and volition may refult from any mechanical organization,

Reid.

organization, or any combination whatever of matter and motion.

REISKE (John James), a most profound scholar and sagacious critic, was born in 1706 at a small town of the duchy of Anhalt. After struggling with some difficulties in his school education, in which, however, he, by perseverance, obtained considerable advantages, he went, in 1733, to Leipsic; where he continued, for the sake of study, five years. Here he accomplished himself in Arabic, and translated and published a book from that language. In order to prosecute his study of Arabic with greater effect, he travelled on foot, and with many difficulties, to Leyden. Here he was employed in arranging the Arabic manuscripts, for which, however, he received a very scanty compensation; and here also he translated from the German and French, into Latin, various essays sent him by Dorville, whom he had visited in his journey, and who afterwards inserted these papers in the *Miscellanea Critica*. Dorville was so well pleased with his skill and diligence, that he employed him in more important concerns. At his desire, Reiske translated the whole of the Chariton from the Greek, and the Geography of Abulfeda from the Arabic, into Latin. At Leyden he continued for the space of eight years; where a storm of jealousy and calumny, excited against him by the younger Burman, finally induced him to change his residence. This was principally owing to the freedom he used with respect to the edition of Petronius, edited by the younger Burman at Leyden; however, before he quitted it, he took the degree of doctor of physic, which was given him in a manner which did him the highest honour. He then visited different parts of Germany, till he at length settled at Leipsic a second time. Here, for twelve years, notwithstanding he was made professor of Arabic, he experienced all the inconveniences of poverty, and was obliged to undergo a great deal of drudgery for booksellers, and the editors of periodical publications, to procure a subsistence; at this period, in particular, the *Acta Eruditorum* were greatly indebted to him. Amidst all these hardships, however, he found opportunity to write, and to publish, his *Animadversiones in Auctores Græcos*, in five volumes; a work of extraordinary learning and merit. In 1758, by the death of Haltausius, he obtained a situation at once honourable and lucrative, which placed him above want, and enabled him to follow his favourite pursuits at ease. He was made rector of the academy at Leipsic, in which office he continued till the time of his death. In 1764, he married Ernestina Christina Muller, a woman of wonderful attainments, whose knowledge was hardly inferior to his own and particularly in Greek literature. She assisted him in all his literary labours, and especially in his immortal work of the "Edition of the Greek Orators." Thus, in the manner most grateful to himself, Reiske consumed the remainder of his life, which continued till 1774, when he died possessed of the highest reputation. The number of works which he superintended and published is very great; but it will be sufficient to name those which are most sought after and esteemed. These are, the "Remarks upon Greek Authors," before mentioned. An "Edition of the Greek Orators," in 12 vols 8vo, which was finished by his widow. "Dionysius Halicarnassensis," in 7 vols. "Plutarch's Works," in 9 vols. "Theocritus, &c. &c." This John James Reiske must not be confounded with *John Reiske*, rector of the college of Wolfenbuttel, who was also a learned man, and published various works*.

REMONSTRANTS, in church history, a title given to the ARMINIANS (See that article, *Encycl.*) by reason of the remonstrance which, in 1610, they made to the States of Holland, against the sentence of the synod of Dort, which condemned them as heretics. Episcopius and Grotius were at the head of the *Remonstrants*, whose principles were first openly patronised in England by Archbishop Laud. In Holland, the patrons of Calvinism presented an address in opposition to the remonstrance of the Arminians, and called it a counter-remonstrance. Hence the Dutch Calvinists were termed *Counter remonstrants*. Much controversy was carried on by these rival sects, which, on the side of the Calvinists, was extremely illiberal.

REMORA, or SUCKING FISH, a species of ECHENEIS (See *Encycl.*). M. Vaillant found, upon different parts of his enormous *ray* (See RAJA in this *Suppl.*) about twenty small sucking fish, or *remoras*, fastened so firmly, that they did not drop off when he was hoisted on board. Some naturalists have said, that the head of the sucking fish is viscous on the lower part, and furnished with rough points similar to the teeth of a file; and, according to them, it is by means of these two qualities, its roughness and viscosity, that it is enabled to adhere to other fish.

"Figure to yourself (says one of them) a row of nineteen sharp-edged and dentated laminæ, placed crosswise, and issuing immediately from the rim of the lower jaw, and you will have a just idea of the part with which the remora makes itself fast."

This description (says Vaillant) is exact as far as relates to the figure and number of the dentated laminæ; but it places them on the lower part of the head, whereas they are, in reality, on the upper. Accordingly, when the remora fixes itself, it is obliged to turn upon its back, with its belly upwards.

If the two white fish, however, that posted themselves on the arms of the ray, and served him as pilots, be of the remora species, as he is inclined to think, the laminæ by which that variety adheres to other fishes must be on the lower part of the body, since the two pilots continued in their natural position, and had no occasion to turn over to fix themselves at their post.

REPETEND, in arithmetic, denotes that part of an infinite decimal fraction, which is continually repeated *ad infinitum*. Thus in the numbers 2·13 13 13 &c. the figures 13 are the repetend, and marked thus $\dot{1}\dot{3}$.

REPUBLICANS, the name given by Vaillant, with some propriety, to a kind of birds which were observed in South Africa, both by him and Paterson, to inhabit apparently the same enormous nest. Cutting one of these nests in pieces with a hatchet, he perceived that the principal and fundamental piece consisted of a mass of strong coarse grass (called by the Hottentots *Boshmen's grass*), without any mixture, but so compact and firmly knit together as to be impenetrable to the rain. This nucleus is the commencement of the structure; and each bird builds and applies to it its particular nest. But these cells are formed only beneath and around the mass; the upper surface remains void, without, however, being useless; for, as it has a projecting

* Dict. new edit.

Republicans, Residual.

jecting rim, and is a little inclined, it serves to let the water run off, and preserves each dwelling from the rain. Figure to yourself a huge irregular mass, the summit forming a kind of roof, and all the other parts of the surface completely covered with cells squeezed one against another, and you will have a tolerably accurate idea of these singular edifices.

Each cell is three or four inches in diameter, which is sufficient for the bird. But as they are all in contact with one another through the greater part of the surface of the mass, they appear to the eye to form but one building, and are distinguishable from each other only by a little external aperture, which serves as an entrance to the nest; and even this is sometimes common to three different nests, one of which is situated at the bottom, and the other two at the sides.

The nest which he examined contained 320 inhabited cells, which, supposing a male and female to each, announce a society of 640 individuals. Such a calculation, however, would not be exact; for whenever our author fired at a flock of these birds, he always killed four times as many females as males. "For the rest (says he), these birds have nothing very remarkable in their plumage. It is an uniform brown grey, diversified by a few black spots on the sides; and a large patch of the same colour on the throat. The male is a little larger than the female; in other respects they exactly resemble each other."

RESIDUAL ANALYSIS, a calculus proposed by the inventor, Mr Landen, as a substitute for the method of fluxions. The object of this substitution was to avoid introducing the idea of motion, and of quantities infinitely or indefinitely small, into mathematical investigation. The residual analysis accordingly proceeds, by taking the difference of the same function of a variable quantity in two different states of that quantity, and expressing the relation of this difference to the difference between the two states of the said variable quantity itself. This relation being first expressed generally, is then considered in the case when the difference of the two states of the variable quantity is = 0, and by that means it is evident, that the same thing is done as when the fluxion of a function of a variable quantity is assigned by the ordinary methods.

The evolution of the functions, considered in this very general view, requires the assistance of a new theorem, discovered by Mr Landen, and remarkable for its simplicity, as well as its great extent. It is, that if x and v are any two variable quantities, $\frac{x^{\frac{m}{n}} - v^{\frac{m}{n}}}{x - v}$

$$: x^{\frac{m}{n}-1} \times \frac{1 + \frac{v}{x} + \frac{v^2}{x^2} + \frac{v^3}{x^3} + \cdots (m)}{1 + \left(\frac{v}{x}\right)^{\frac{m}{n}} + \left(\frac{v}{x}\right)^{\frac{2m}{n}} + \left(\frac{v}{x}\right)^{\frac{3m}{n}} \cdots (n)}$$

where m and n are any integer numbers.

This theorem is the basis of the calculus; and from the expressions $x^{\frac{m}{n}} - v^{\frac{m}{n}}$, and $x - v$ having the form of what algebraists call *residuals*, the ingenious inventor gave to his whole method the name of the *residual analysis*.

Residual ‖ Revivification.

The first account of this method was published by Mr Landen in 1758, under the title of a *Discourse concerning the Residual Analysis*. The first book of the Residual Analysis itself was published in 1764; and contained an explanation of the principles of the new calculus, with its application to several of the most considerable problems belonging to the direct method of fluxions. The second book was intended to give the solution of many of the most difficult problems that belong to the inverse method of fluxions, or to the integral calculus; but it has never been published: a circumstance which every one, who has taken the trouble to study the first part of the work, will very much regret.

If we estimate the value of the residual analysis from the genius, profound knowledge, and extensive views required to the discovery of it, it will rank high among works of invention: but if, on the other hand, we estimate its value by its real practical utility, as an instrument of investigation, we must rate it much lower. When compared with the fluxionary calculus, which it was intended to supersede, its principles, though in appearance more rigorous, are much less easily apprehended, much less luminous, and less direct in their application; and therefore, as a means of extending the bounds of mathematical science, it must ever be regarded as vastly inferior to the latter (A).

RETICULA, or RETICULE, in astronomy, a contrivance for measuring very nicely the quantity of eclipses, &c. This instrument, introduced some years since by the Paris Academy of Sciences, is a little frame, consisting of 13 fine silken threads, parallel to, and equidistant from, each other, placed in the focus of object-glasses of telescopes; that is, in the place where the image of the luminary is painted in its full extent. Consequently the diameter of the sun or moon is thus seen divided into 12 equal parts or digits: so that, to find the quantity of the eclipse, there is nothing to do but to number the parts that are dark, or that are luminous. As a square reticule is only proper for the diameter of the luminary, not for the circumference of it, it is sometimes made circular, by drawing six concentric equidistant circles, which represents the phases of the eclipse perfectly. But it is evident that the reticule, whether square or circular, ought to be perfectly equal to the diameter or circumference of the sun or star, such as it appears in the focus of the glass; otherwise the division cannot be just. Now this is no easy matter to effect, because the apparent diameter of the sun and moon differs in each eclipse; nay, that of the moon differs from itself in the progress of the same eclipse. Another imperfection in the reticule is, that its magnitude is determined by that of the image in the focus; and of consequence it will only fit one certain magnitude. See MICROMETER, *Encycl.*

REVETEMENT, in fortification, a strong wall built on the outside of the rampart and parapet, to support the earth, and prevent its rolling into the ditch.

REVIVIFICATION, in physiology, the recalling to

(A) For this view of the *Residual Analysis*, we are obliged to Mr Playfair professor of Mathematics in the University of Edinburgh.

Revivification, French Revolution, 1795.

to life of animals apparently dead. There are many kinds of insects which may be revivified, after all the powers of animation have been suspended for a considerable time. Common flies, small beetles, spiders, moths, bugs, &c. after being drowned in spirit of wine, and continuing apparently dead for more than a quarter of an hour, have been restored to life merely by being thrown among wood-ashes slightly warm.

While Dr Franklin resided in France, he received from America a quantity of Madeira wine which had been bottled in Virginia. In some of the bottles he found a few dead flies, which he exposed to the warm sun, it being then the month of July; and in less than three hours these apparently dead animals recovered life which had been so long suspended. At first they appeared as if convulsed; they then raised themselves on their legs, washed their eyes with their fore feet, dressed their wings with those behind, and began in a little time to fly about.

But the most extraordinary instance of revivification that we ever heard of, is the following: In the warmer parts of France there is an insect very destructive to rye, which seems to begin its operations at the root of the plant, and gradually to proceed upwards to the ear. If the plant be completely dried while the insect is in the root or stem, the animal is irrecoverably killed; but after it has reached the grain, the case is very different. There have been instances, which are noticed in the Academy of Sciences, of these insects being brought to life in a quarter of an hour, by a little warm water, after the grains, in which they were lodged, had been kept dry for 30 years.

What is the metaphysician to think of these phenomena, or what conclusion is he to draw from them with respect to the mind or sentient principle? If he be a sober man, he will draw no conclusion; and for this very good reason, that of the sentient principle of insects, and indeed of every animal but man, he knows nothing. He is conscious that it is the same individual being, which, in himself, thinks, and wills, and feels; he knows, that part of his thought is not in one place and part of it in another; and therefore he rationally concludes that this thinking being is not matter, whilst experience teaches him that it quits the material system as soon as that system becomes completely unfit to discharge its functions, and that when it has once taken its flight, it cannot be recalled. Experience teaches him, on the other hand, that the sentient principle of these insects does not quit the material system as soon as that system seems unfit for its functions; and hence he ought to infer, that the minds of men and of insects (if we may use such language), though probably both immaterial, are very different substances; and that the bond which unites the material and immaterial parts of an insect, is certainly different from that which unites the mind and body of man. This is the only inference which can be legitimately drawn from these phenomena; and he who makes them the basis of materialism, must have his judgment warped by some passion or prejudice.

216 Narrative continued

REVOLUTION OF FRANCE. We formerly presented to our readers a concise statement of the commencement and progress of this extraordinary event (See REVOLUTION, *Encycl.*). The singularity of its nature, and the important place which it must hereafter occupy in the moral and political history of mankind, require that we should now resume and continue the detail of its wide-wasting career. We left the subject towards the commencement of the year 1795, at the close of that wonderful campaign, during which the armies of the Republic had exerted themselves with such unparalleled success in every direction. On the one side they had crossed the Pyrennees, and shaken the Spanish monarchy to its centre; while on the other they had driven the united forces of Austria, Prussia, and Britain, from the walls of Landrecies across the Rhine, at all points from Hageneau to the sea, and had finally closed their efforts by the conquest of Holland. At that period, though a prolongation of hostilities was threatened, we scarcely expected that Europe was so soon to witness, or we to record, a succession of military enterprises of a still more romantic and extraordinary nature, the scene of which was even to extend into barbarous countries, where the opinions and the quarrels of the European nations had hitherto remained unknown.

217 Diminished energy of the Convention,

The campaign of 1794, however, was not immediately followed by any important military exertions. The British troops were recalled home, Prussia had been gradually withdrawing from the coalition, and the Austrian armies remained upon the defensive. Neither was the French government in a situation which could enable it to renew its enterprises with vigour, or to give much trouble to the allies. The Convention still existed; but it was no longer that terrible assembly which, under Robespierre and his associates, had, in the short period of fifteen months, reduced two thirds of France under its dominion, and sent forth armies which the combined strength of the rest of Europe seemed unable to resist. While its authority remained almost concentrated in one man, and while the fear of foreign invasion, and the new born enthusiasm for freedom, induced the people to submit to every measure of government, however oppressive or arbitrary, the power of the Convention, and the number of its armies, were unbounded. The dreadful price, however, which they had paid for liberty, and the facility with which they saw it might be lost, had now diminished the political zeal of all classes of citizens. The removal of the foreign armies had dispelled the dread of invasion, and the death of Robespierre, by dissolving the unity of its efforts, and suffering it to fall into contending factions, had greatly weakened the authority of the Convention, and diminished its efficiency as a government.

The fall of Robespierre had been accomplished by two separate conspiracies. At the head of one of these were, Barrere, Billaud Varennes, and Collot d'Herbois, who had been members of the Committee of public safety. The other conspiracy consisted of members of the Convention who did not belong to the committees, and had no immediate share in the administration. Among these, Tallien, Bourdon de l'Oise, and Lecointre of Versailles, were conspicuous. After the destruction of their mutual tyrant, a contest for power took place between these parties. The popularity of Robespierre had once been so considerable, and all men had submitted so tamely to his dominion, that both parties accounted it necessary, in their speeches and writings, to justify to the nation the share they had taken in accomplishing his ruin. It was easy to be eloquent upon such a topic; but its discussion naturally operated to the discredit of the members of the committee, and of the

218 And discredit of the Jacobins,

French Revolution, 1795. the more violent Jacobins, who had been the immediate instruments for carrying into effect his sanguinary measures. They nevertheless retained possession, for some time, of a considerable portion of power. The current of public opinion, however, ran so strongly against them, and the restoration to their seats in the Convention of the seventy one imprisoned members of the Girondist party, added so much to the strength of their antagonists, that they gradually lost their influence, and were threatened to be brought to trial for their conduct.

As early as August 1794, Lecointre of Versailles had denounced the members of the old committee of safety; but his accusation at that time produced little effect. Towards the end of that year, however, their approaching fall became evident. On the 26th of December the Convention ordered, on the motion of Clauzel, that the committees should immediately report upon the conduct of the representatives denounced by Lecointre and all France. Accordingly, on the following day, Merlin of Douay reported, in the name of the committees, that there was no cause for inquiry into the conduct of Vouland, Amar, and David; but that there was room for examining the conduct of Barrere, Billaud Varennes, Collot d'Herbois, and Vadier.

219 Whose leaders were accused, In consequence of this report, a committee of twenty-one members was appointed to make the enquiry. On the 2d of March this year (1795), Saladin presented the report of the commission; in which these four deputies were accused of having participated, as members of the governing committee, in the tyranny and atrocious measures of Robespierre. Their trial commenced before the Convention on the 22d of March; but previous to that period, Vadier had made his escape. The others remained, and rested their defence upon this ground, that although members of the committee of safety, they had no power to resist Robespierre, and that they were not more culpable in having acquiesced in his tyranny than the other members of the Convention, who had all been overpowered for the time by the knowledge that instant destruction awaited every man who should dare to oppose his measures. Except in the case of the cruelties committed by Collot d'Herbois at Lyons, this defence was probably by no means destitute of foundation. It had much weight with the nation at large; in whose eyes it tended, not to exculpate the three persons now accused, but to criminate and degrade the character of the whole Convention.

Carnot, Lindet, Cambon, Duhem, and the other members of what was now called the *Jacobin party*, defended their leaders with considerable ability, and with much vehemence. Nor was the party less active without doors than within the hall of the Convention.

220 And defended by an insurrection For some time they had drawn their friends to the capital from all quarters of the country; and in the morning sitting of the first of April, they commenced their operations by an open insurrection. An immense multitude having assembled in the suburbs, proceeded to the hall of the Convention. A real or factitious scarcity existed at the time. Taking advantage of this circumstance, they pretended they were going to petition for bread; and this pretence drew numbers along with them who had no share in their designs.

Boissy d'Anglas, a conspicuous member of the moderate party, was addressing the Convention upon the means of removing the present scarcity when the insurgents arrived, drove the centinels from their posts, and suddenly filled the hall. They tumultuously demanded "Bread, and the Constitution." The Jacobin party supported the insurgents; and one of the multitude, in a vehement harangue, exclaimed, "We are men of the 14th of July, of the 10th of August, and of the 31st of May." He demanded, that the Convention should change its late measures, that the people should no longer be the victims of mercantile rapacity, and that the accused patriots should not be sacrificed to the passions of their antagonists. The Convention ordered the tocsin to be rung, and the people of Paris to be called to arms. General Pichegru was in Paris at the time; and, upon the motion of Barras, he was appointed to the command of the military force.

221 Which is quelled by Pichegru. The citizens of Paris, who remembered with horror the domination of Robespierre and his adherents, and now saw themselves menaced with its return, instantly called each other to arms, and assembled, by six in the evening, for the protection of the Convention, to the amount of 20,000 men. Till that time the assembly had remained under no small disquietude, surrounded by the insurgents, and listening to the addresses of their orators, and the speeches of the Jacobin minority in their favour. The majority was now rescued from this state of constraint; and, on the motion of Dumont, without proceeding farther in the trial, it was decreed that Barrere, Collot d'Herbois, and Billaud Varennes, should immediately be transported to Guiana.

During the following day the insurgents were completely subdued; and the majority of the Convention, taking advantage of their victory, decreed the arrest and confinement, in the castle of Ham in Picardy, of several of the most obnoxious of their antagonists. Among these were Leonard Bourdon, Duhem, Chasles, Choudieu, Ruamps, Foussedoire, Huguet, Bayle, Lecointre, Cambon, Thuriot Maignet, Hentz, Crassons, and Levasseur. 222 Victory of the Convention By departing from the punishment of death, and adopting that of banishment on this occasion, the Convention expected to diminish the ferocity of the contending factions in the state, by rendering the result of a political defeat less fatal than formerly. The design was good; but in attempting to accomplish it, they established the pernicious precedent of inflicting punishment without a trial, which could scarcely fail to prove highly dangerous, if not ultimately fatal, to all their prospects of a free and just government.

223 Proposal for a new constitution. The Convention now followed up its victory with the popular measure of preparing for its own dissolution, by endeavouring to frame a fixed constitution for the Republic. The constitution which had been decreed in 1793, under the auspices of Robespierre, was considered as impracticable, and a committee was appointed to report upon the measures which ought now to be adopted. It consisted of Sieyes, Cambaceres, Merlin of Douay, Thibaudeau, Mathieu, Le Sage of Eure and Loire, and Latouche. On the 19th of April, Cambaceres reported, that it was the opinion of this committee that a commission should be appointed to frame an entirely new constitution. The Convention accordingly appointed the following persons to this important office, Le Sage, Louvet, Boissy d'Anglas, Creuze, Latouche, Bertier, Daunow, Baudin, Durand, Maillane, Languinais, La Reveillere Lepaux, and Thibaudeau. All other citizens of every description were

French Revolution, 1795.

at the same time invited to communicate projects upon the subject, and the committee was required to order the best conceived of these to be printed.

The Convention farther gratified the feelings of the great majority of the nation, by bringing to trial Fouquier Jenville the president, and fifteen judges and jurors of the late revolutionary tribunal. They were convicted on the 8th of May, and executed on the following day, amidst the execrations of a multitude of spectators.

224 New insurrection of the Jacobins.

In the mean time, though defeated on the 1st and 2d of April, the Jacobins by no means considered themselves as subdued. On the contrary, they were preparing a new and more extensive insurrection, which should not, like the former, be confined to the capital. They fixed upon the 20th of May as the day of revolt. Thuriot, and Robespierre's financier Cambon, had found means to escape from the castle of Ham in Picardy, and to come to Paris. They concealed themselves in the suburb St Antoine, and from thence gave counsel to their party, and urged them to action. The scarcity of bread had increased, and advantage was again taken of this circumstance. For some days the walls were covered in various places of Paris with printed accusations against the Convention of withholding bread from the people, and attempts were made to excite the troops in the city to join the disaffected party. On the evening of the 19th, a paper was openly distributed in the different sections, explaining the object of the approaching insurrection. It declared insurrection to be the most sacred duty of the people, and called upon the citizens of Paris to proceed in a mass to the Convention, to demand from it bread and the establishment of Robespierre's constitution, together with a new election of national representatives.

On the morning of the 20th, the tocsin was rung, and drums beat to arms in the suburb St Antoine, which had always been the quarter of the city in which the Jacobins possessed the greatest strength. Upon this alarm the Convention assembled; but although the intended insurrection was no secret, and though the committee of public and general safety now made a report, in which they confessed their previous knowledge of it, yet it does not appear that any vigorous measures of precaution had been taken; for it was only at the instant when the insurgents were actually approaching, that General Hoche was appointed to command the armed force, and was sent forth to assemble the military and the citizens for the defence of the Convention. In the mean time, the multitude surrounded the hall. They soon overpowered the guards, and burst into the midst of the assembly. In all the turbulent days of the revolution, the women of Paris have never failed to act a conspicuous part. On this occasion they greatly augmented the crowd by their numbers, and the tumult by their cries of "Bread, and the constitution of 1793," which was the rallying exclamation of the party. After some fruitless efforts to restore tranquillity, Vernier the president, an old man, resigned the chair to Boissy D'Anglas, who remained in it with much firmness during the day. The whole strength of the insurgents had not arrived at once; for the first party that approached, although they forced their way into the hall, were soon repulsed by the aid of a few soldiers and citizens, who came to the assistance of the Convention. A short interval of tranquillity was thus obtained; but the attack was speedily renewed with double fury by armed men, who subdued all opposition, and entered the hall with cockades, on which was written the inscription, "Bread, and the constitution of 1793." While things were in this state, a citizen of the party of the Convention rashly tore off the hat of one of the insurgents, and was immediately assaulted with swords by the multitude. He fled towards the president's chair, and was killed at the side of it by a musket shot. Ferand, one of the members, having attempted to rescue him, was also attacked. He escaped into one of the passages, where he was also killed, and his head was brought into the Convention upon a pike. The greater number of the members now gradually departed, and left the hall in possession of the insurgents, who acted with some regularity, and proposed a variety of laws favourable to their party, which were instantly decreed. Duroi, Duquesnoi, Bourbotte, and Goujon, were the members who stood most openly forward on this occasion, and appeared as chiefs of the insurrection. But their triumph only lasted a few hours. Towards the evening a large body of citizens joined the military, and marched to the aid of the Convention. Having overcome the insurgents, they entered the hall in great force, and restored the powers of the majority. The decrees that had been forced upon them were repealed as speedily as they had been enacted, and the deputies who had proposed or supported them were arrested.

French Revolution, 1795.

225 Who murder some of the Convention, and drive it from the hall.

The citizens of Paris, and even the members of the Convention, appear now to have fancied their victory complete; for they adopted no adequate measures to prevent a new disturbance. But the Jacobins did not so easily give up their own cause. On the following day they once more assembled in the suburbs, and in the afternoon they returned to the attack. They took possession of the Carousal without opposition, and pointed some pieces of cannon against the hall of the Convention. This assembly was now unprotected, and attempted not to subdue, but to flatter, the insurgents. A deputation of the members was sent forth to fraternise with them, and to carry forth two decrees passed at that instant, which ordained that bread should abound; and that Robespierre's constitution of 1793 should immediately be put in force. The insurgents, in return, sent a deputation to the Convention, to express their satisfaction with the decrees, to demand the release of the imprisoned patriots, and the punishment of those who preferred money to assignats. The Convention pretended to agree to all their demands, and the president was ordered to give to the deputation the fraternal embrace.

226 Meanness of the Convention.

The 22d, which was the third day of the insurrection, appears to have been passed by both parties in a strange degree of inaction. The Convention proceeded in its ordinary business; and the Jacobins, at their head quarters in the suburb St Antoine, were occupied in consultations and preparations for new movements. But on the following day the citizens assembled at their sections, and hastened from thence to the Thuilleries to defend the Convention. Considerable bodies of the military were also collected, and the assembly at last resolved to act upon the offensive. A decree was passed, declaring, that if the suburb St Antoine did not instantly surrender its arms and cannon, together with the

French Revolution, 1795.

the murderer of Ferand, it should be considered as in a state of rebellion. The conventional generals were at the same time ordered to reduce it by force. The insurgents now found themselves unequal to the contest,

227 Its victory over the Jacobins.

and were compelled to surrender without conditions by the inhabitants of the suburb, who dreaded the destruction of their property by military operations. Several soldiers being found among the prisoners, were put to death; and six members of the Convention were tried and condemned on this occasion by a military commission. Three of these perished by self slaughter, and three were executed. The majority of the Convention, elated by their victory, ordered back Collot D'Herbois, Billaud Varennes, and Barrere to take their trial; but the two former had sailed before the arrival of the courier. Barrere only remained, and he was brought back and imprisoned.

In the mean time, the Jacobins in the south were not less active than their brethren at Paris On the 20th of May they formed a vigorous insurrection at Toulon They seized the gates, and mounted them with cannon; they liberated such of their associates as had been imprisoned, and detained the fleet which was about to sail. Having begun their operations in this successful manner, they marched from Toulon towards Marseilles. Their force amounted to three thousand men and twelve pieces of cannon. They were encountered on their way, however, and defeated by Generals Charton and Pactod. Three hundred of them were carried prisoners to Marseilles, and Toulon was speedily retaken.

The party of the *Mountain*, as it had been called, or of the violent Jacobins, who wished to revive the reign of terror and the measures of Robespierre, was now reduced very low both in the Convention and out of it. Those who adhered to it were even in many places, and more especially in the south, exposed to very violent persecution. Associations were formed, called Companies of *Jesus* and of the *Sun*, for the purpose of avenging the crimes committed by them during the period of their power. At Lyons several of them were massacred in prison, and many of them in all places perished by assassination. On considering the merciless character of the government of Robespierre and his associates, and the persecution which was suffered under it, not merely by the nobles and the rich, but by every man who was distinguished by integrity, talents, or literature, it may appear surprising that it should have obtained admirers, or that any number of individuals should have been found willing to hazard their lives to procure its restoration. Accordingly, from the period of the fall of its leader, the party had gradually been forsaken by its adherents; and the more closely its conduct was considered, it lost ground the more rapidly in the estimation of the public. After the unsuccessful insurrections of the 20th of May, it was treated with the utmost contempt, and its unpopularity was extreme. Still, however, a party remained. It was small, indeed, but its members compensated the inferiority of

228 Who still retain their spirit;

their numbers by superior enterprise and activity. They consisted of outrageous republicans, whose heated imaginations beheld royalty and aristocracy in every proposal for sober and regular government. In the conduct of Robespierre, they remembered only the energy of his measures, by which France was enabled to triumph over the combined efforts of the kings of Europe; and overlooked the atrocities by which he had brought disgrace upon their cause, and rendered his party odious to their own countrymen, as well as to the neighbouring nations. Amidst this universal odium, however, the Jacobins did not despair of rising once more into power; and it is not a little singular, that we must date the revival of their strength from the period of the unsuccessful insurrections which we have just recorded, and which seemed to have extinguished their hopes for ever.

The unpopularity under which the Jacobins laboured soon began to affect the Convention itself. The tame submission of that body to the government of Robespierre was now remembered. It was recollected, that the majority of its members had been the instruments of his power, and had applauded, or at least acquiesced in his crimes. As the press was now free, and the reins of government unsteadily held, their conduct was represented to the public in the most odious colours. A celebrated song, *Le Reveil du Peuple*, became extremely popular, as the means of marking dislike both to the Convention and to the Jacobins; and their conduct was canvassed with the utmost bitterness in a great variety of publications, but more especially in a journal that at this time attracted much notice and which was conducted by Freron, who had himself been a Jacobin, but had now abandoned his party.

229. And terrify the Convention.

In this state of things, the majority of the Convention speedily began to repent of their late victory over the Jacobins. In the first efforts of their zeal, they had taken measures for the immediate formation and establishment of a settled constitution to supersede their own authority; but they now regretted their rashness, when they perceived, from the temper the nation was in, that the men, the most avowedly hostile to their character and measures, would without doubt be elected as their successors. They, and their friends, had arisen to great distinction and wealth under the revolutionary government; and they now began to dread, not only the loss of power, but also a severe investigation of their conduct. These considerations soon produced their natural effects. The decrees for forming and putting in force the constitution could not decently be recalled; but the majority of the Convention set about devising means for rendering them of little importance, so far as they themselves were concerned.

230 New constitution, consisting of

On the 23d of June, Boissy D'Anglas presented the report of the committee that had been appointed to prepare the plan of a constitution. It began, like the former constitutions, with a declaration of the rights of man; and in addition to this, consisted of fourteen chapters, upon the following subjects:—The extent of the territorial possessions of the Republic, the political state of citizens, the primary assemblies, the electoral assemblies, the legislature, the executive power, the municipal bodies, the judicial authority, the public force, public instruction, the finances, foreign treaties, the mode of revising the constitution, and, lastly, an enactment, that no rank or superiority should exist among citizens, excepting what might arise from the exercise of public functions.

The primary assemblies were to possess the right of electing the members of the electoral assemblies, and also the justices of the peace. The electoral assemblies were to nominate the judges and the legislators of the state.

French Revolution, 1795.

ſtate. The legiſlature was divided into two aſſemblies; the one of which conſiſted of 250 members, and was called the *Council of the Ancients*, as none but married men and widowers above 40 years of age could be members of it. The other aſſembly or council conſiſted of 500 members, and poſſeſſed the excluſive privilege of propoſing the laws; the Council of Ancients being only intitled to reject or approve, without power to alter the decrees preſented to it. To this rule there was one exception, which was afterwards employed as the means of overturning the whole fabric of the conſtitution; the Council of the Ancients might decree the removal of the legiſlature from its ordinary place of ſitting. To this decree the approbation of the Council of Five Hundred was not neceſſary; and when once enacted, it could not be reconſidered even by the Council of Ancients itſelf. One-third of the members of the two Councils was to be elected annually. A member might be once re-elected, but he could not be elected a third time till an interval of two years had elapſed.

231 Two Councils and an

232 Executive Directory.

The executive power was intruſted to five perſons of forty years of age at leaſt, to be ſtyled the *Executive Directory*. Its members were elected by the two Councils; the Council of Five Hundred electing ten times the number of candidates that might be neceſſary to fill up the vacancies, and the Council of Two Hundred and Fifty nominating the directors from this liſt of candidates. One member of the Directory was to go out annually; ſo that the whole might be changed every five years. The Executive Directory had no vote in the enactment of laws; but it ſuperintended their execution, regulated the coining of money, and diſpoſed of the armed force. Foreign treaties made by it were not binding till ratified by the legiſlative body, nor could it make war without the authority of a decree of the two aſſemblies. The public functionaries were to receive ſalaries, and to appear dreſſed in an appropriated habit.

Each article of this conſtitution was ſeparately diſcuſſed; and on the 23d of Auguſt the whole was declared to be complete, and ordained to be tranſmitted to the primary aſſemblies for their approbation. Previous to this reſolution, however (that is, on the 22d of the ſame month), the majority of the Convention had brought forward the grand meaſure by which they meant to provide for their own ſafety, and the ſafety of their friends and adherents, againſt the change which the public opinion had undergone concerning them. They decreed, that at the approaching general election, the electoral bodies ſhould be bound to chooſe *two-thirds* of the new legiſlature from among the members of the preſent convention; and they afterwards decreed, that, in default of the election of two thirds of the Convention, the Convention ſhould fill up the vacancies themſelves.

233 The Convention fetters the freedom of election.

Theſe decrees were tranſmitted, along with the Conſtitution, to the primary aſſemblies, to be accepted or rejected by them. Many of the primary aſſemblies underſtood, that they could not accept of the conſtitution without accepting along with it the law for the re-election of the *two-thirds*. The point had, in all probability, been purpoſely left under a certain degree of ambiguity; and as the people were now weary of this Convention, they acquieſced in any conditions that gave them the proſpect of one day getting quit of it. But at Paris, and in the neighbouring departments, where the ſubject was more accurately inveſtigated, the public diſapprobation of the Convention diſplayed itſelf with great vehemence.

234 Conſequences of this conduct.

There was indeed ſomething extremely aukward in the decree about the re-election of two thirds of the Convention. That body might, if neceſſary, have continued its own exiſtence for ſome time longer, or it might have diſmiſſed one third of its number by ballot or otherwiſe, and allowed a new election only to that extent; but a compulſory election was an abſurdity ſo new, and ſo obvious, that it gave their antagoniſts every advantage againſt them. Accordingly, at the meetings of the ſections of Paris, the laws for the re-election were rejected with contempt, and their abſurdity demonſtrated with much acrimony. In conſequence of the debates which took place at theſe meetings, the minds of men were gradually inflamed, and it became obvious that a political convulſion approached. On the one ſide, the Convention took care to publiſh daily the approbation of the decrees, along with the conſtitution, by the majority of the primary aſſemblies, by moſt of which the two had been confounded and accepted in the groſs. Its committees alſo called in the aid of the troops of the line for its protection. On the other hand, the language of the ſections became every day more violent. The whole Convention was repreſented as a band of tyrants and of murderers, the aſſociates of all the cruelty of Robeſp[illegible] Mountain party. It was even propoſe[illegible] trial every individual member of the aſſe[illegible] new revolutionary tribunal, and to puniſh him according to his demerits.

For ſome time much anxiety prevailed on both ſides. Numerous deputations were repeatedly ſent from the ſections to the Convention, to remonſtrate againſt the obnoxious decrees. But the eagerneſs with which theſe remonſtrances were made, ſerved only to convince more ſtrongly the members of the Convention of the danger to themſelves as individuals which would attend a reſignation of their power, and confirmed the reſolution they had taken to retain it. The deputies of the ſections having obtained inſpection of the records of the convention, aſſerted, that the national majority, if rightly numbered, had rejected the decrees, as every aſſembly that voted in oppoſition to them was only numbered as one vote, however numerous its members might be; which enabled the primary aſſemblies of remote diſtricts to outvote the more populous ſections of Paris and other great towns. Whereas it was ſaid, that if the individual voters were counted, it would be found that the decrees were diſapproved of by a conſiderable majority. All this was diſregarded by the Convention, and the ſections prepared to decide the diſpute by arms. The firſt ſtep taken by them, however, was ill concerted. A notion was propagated, that as ſoon as the primary aſſemblies or ſections had choſen the electors who were to chooſe the members of the new legiſlature, the national ſovereignty became veſted in theſe electors, and that they had a right to aſſume the government in their various diſtricts. Accordingly, about 100 of the electors of Paris aſſembled in the hall of the French theatre in the ſuburb St Germain, previous to the day of meeting appointed by the Convention. Having choſen

French Revolution, 1795.

De Nivernois (formerly the Duke de Nivernois) their preſident, they began their debates. The Convention was alarmed, and inſtantly ſent a body of the military to diſmiſs the meeting as illegal. This was eaſily accompliſhed, as the citizens had not been unanimous with regard to it, and no meaſures were taken for its protection.

Notwithſtanding this firſt advantage on the ſide of the Convention, the ſections regarded its power with contempt, and imagined themſelves ſecure of ultimate ſucceſs. In every political conteſt that had hitherto occurred ſince the commencement of the revolution, the immenſe population of the capital had given a deciſive ſuperiority to the faction whoſe ſide it eſpouſed. The citizens alſo regarded with indifference the armed force with which the Convention had ſurrounded itſelf, from a notion, which they fondly entertained, that the military would in no caſe be brought to act againſt the people. It would appear that the Convention itſelf entertained ſome jealouſy upon this head, and did not account itſelf entirely ſafe under the protection of the ſoldiers. On this occaſion, therefore, it had recourſe to a new ally, and beſought the aid of thoſe very Jacobins whom it had almoſt cruſhed on the 24th of May. The members of the Convention were odious to the ſections of Paris, on account of their participation in the revolutionary crimes and meaſures of Robeſpierre; but this very circumſtance endeared them to the Jacobins, whoſe character it was to imagine that they had never enough of war abroad or of revolution at home. It was eaſy therefore to bring about a reconciliation between the Convention and theſe men. Several hundreds of them were diſmiſſed from the priſons, where they had been confined ſince the two laſt inſurrections, and they were now put in requiſition to defend the legiſlative body.

235 The Convention courts the Jacobins.

When the ſections of Paris beheld the Convention ſurrounded by thoſe Jacobins who had been the unrelenting agents of the government of Robeſpierre, and who were now denominated *terroriſts* and men of blood, their ardour for action became unbounded. They aſſembled in arms at their different ſections on the 12th Vendemaire (October 4th); but they do not ſeem to have acted with much concert, or upon any well digeſted plan of operations. The general deſign of their leaders was to ſeize the members of the Convention, and impriſon them in the church of the Quatre Nations till they could be brought to trial. As this would occaſion a vacancy or interregnum in the government, it was reſolved that all affairs ſhould be conducted by committees of the ſections, till a new legiſlature could be elected. General Miranda, a Spaniard, a native of the Carraccas in South America, who had ſerved in the republican armies, was to be appointed to the chief command of the armed force after the overthrow of the Convention. This man, in his eagerneſs for preferment, had alternately courted all parties, and he now ſeems to have joined the Pariſians upon the ſuppoſition of their being the ſtrongeſt. As he entertained ſome doubts of their ſucceſs, however, he adopted the crooked and timid policy of avoiding the ſtorm by retiring from the city till the combat ſhould be finiſhed, reſolving to return immediately on its concluſion to ſhare the rewards and the triumph of victory.

The Convention, in the mean time, reſolved to ſtrike the firſt blow. For this purpoſe they ſent General Menou to the ſection of Le Pelletier to diſperſe the citizens, whoſe greateſt force was aſſembled there. But this officer, diſliking the ſervice which he was employed to perform, inſtead of proceeding to action, began to negociate with the leaders of the ſections, and ſpent the evening of this day in fruitleſs conferences. The ſections on their ſide appointed General Danican, who had diſtinguiſhed himſelf in the war againſt the Royaliſts in La Vendee to act as their military leader. It would appear, however, that this officer, from the moment that he aſſumed the command, began to deſpair of the cauſe of the ſections. He found them totally deſtitute of cannon, whereas the Convention was ſurrounded by regular troops and a numerous artillery. This inequality in point of weapons appears to have been conſidered by him as a ſufficient reaſon for avoiding an engagement. Occupied in viſiting and arranging the different poſts, he was unacquainted with the diſaffection of the conventional generals. He therefore thought he had done much when he had prevented bloodſhed for another day, and thus the favourable moment for attack was loſt. Whether the ſections would have been ſucceſsful had they been inſtantly led to battle on this important occaſion, cannot now be known. Though the ſuperior officers of the Convention were unfaithful, yet the ſubalterns and the troops in general might have ſtood firm, confirmed as they were by the perſuaſion of their Jacobin auxiliaries. Even in this caſe, however, the fate of a battle might have at leaſt been doubtful. The battalions of Paris were very numerous, their contempt of danger was great, and their ardour unbounded. The mere poſſeſſion of cannon might not in a conteſt againſt ſuch men have afforded ſecurity to the Convention. But the firſt moments of popular enthuſiaſm were ſuffered to paſs away, and that diſtruſt and diſſenſion, which delay never fails to introduce among great and irregular aſſemblages of men, ſoon began to render the conduct of the ſections undecided and weak.

French Revolution, 1795.

The conventional committees, during the night of the 12th Vendemaire (October 4th), diſmiſſed Generals Menou, Raffet, and ſome others, from their ſtations, and gave the command of the troops to Barras. He immediately collected around him a variety of able officers, among whom we find the names of Generals Brune and Bonaparte. With their aſſiſtance he began to provide for a moſt vigorous defence. Troops with cannon were ſtationed in all the avenues leading to the Thuilleries. In caſe any of theſe poſts ſhould be forced, maſked batteries were planted in more retired ſituations. Nor was this all; meaſures were taken for conveying the public magazines of proviſions and military ſtores to St Cloud, whither the Convention prepared to retreat if they ſhould ſuffer a defeat at Paris.

On the 13th Vendemaire (October 5th) from which the inſurrection was afterwards named, both parties remained for many hours upon the defenſive. At laſt, about three o'clock in the afternoon, General Danican made advances to an accommodation by a letter to the committee of public ſafety; in which he ſtated, that the only cauſe on account of which the citizens had taken arms was the dread of a maſſacre being intended by the armed terroriſts who ſurrounded the Convention, and that if theſe men were removed, tranquillity would immediately be re-eſtabliſhed. A civil meſſage was re-

French Revolution. 1795.

turned; but the Jacobin party in the Convention, being now more confident of victory, and wishing to strengthen themselves by the defeat and punishment of their antagonists, it was resolved that the dispute should be decided by arms. It is not correctly known how the contest commenced, but the armed Jacobins are most generally understood to have begun the attack. The citizens on the southern side of the river attempted to reach the Convention by the Quay de Voltaire, but were speedily repulsed by the conventional cannon; but on the northern side of the river, near the Convention, the combat was extremely obstinate. The cannon were repeatedly seized by the citizens, and repeatedly retaken by the troops and the armed Jacobins. It was not till after a contest of four hours that the sections were repulsed and driven to the post of St Roch. This post was also taken after great slaughter, and the sections were driven to their head quarters at the section of Le Pelletier. After a short interval they were pursued thither by the troops of the Convention, who by midnight were masters of the whole city.

236 Subdues the citizens of Paris.

This insurrection was ascribed by the victorious party to the exertions of the Royalists. It is no doubt true, that by this time Royalty was become less unpopular even among the rabble of France than the extreme of Republicanism, as it had appeared in the conduct of the Mountain party. It is also probable, that the Royalists mingled in a contest that had the overthrow of the present Convention for its object; but the insurgents in general seem neither to have avowed nor entertained any farther view than the disarming of the Jacobins, and the obtaining an immediate election of new representatives. The failure of the attempt had the effect of placing the Mountain party once more at the head of the state. This party at first thought of adjourning the new constitution, and of renewing all the terrors of the revolutionary government. This project, however, was opposed in the Convention with so much vehemence and ability by Thibaudeau, that it was renounced. Indeed it was become unnecessary to the safety or ascendency of the men who proposed it, as the decrees for the re-election of two-thirds of the Convention enabled them to retain the full possession of their power. A few members of the moderate party, such as Boissy D'Anglas, Lanjuinais, and Le Sage, were elected by almost every place in France, though they could only sit for one place. Hence the Convention itself had the re-election of nearly two-thirds of its own members; and the Mountain party, which now commanded the majority, was thus enabled to fill the new legislature with its own leaders.

237 Mountain party, or the most violent Jacobins, again at the head of the state.

On the 27th of October the Convention terminated its sittings, and was succeeded by the new legislature as appointed by the Constitution. By its last decrees, a general amnesty was granted for all revolutionary crimes and proceedings. From this amnesty, however, were excepted the emigrants, the transported priests, and all persons concerned in the last insurrection; so that in fact it was merely a pardon granted by the Mountain party to its own friends for all the excesses they had committed. The members of the Convention, who had been imprisoned in the castle of Ham since the Jacobin insurrection in May, were now set at liberty. The members of the revolutionary committees, and other agents of Robespierre in Paris and the departments, were all dismissed from their prisons, and advanced to the most important offices under the new government.

238 First sitting of the new legislature.

As soon as the new legislature had divided itself into two councils, it proceeded to the election of an Executive Directory. Here the genius of the French nation for intrigue instantly displayed itself. The Council of Five Hundred was bound to present to the Council of Two Hundred and Fifty a list of ten times the number of candidates necessary for the office. It fulfilled this duty in the following manner. The majority of the Council of Five Hundred made out a list, consisting of the five following persons, upon whom they wished the election ultimately to fall: Sieyes, Barras, Rewbell, La Reveillere Lepaux, and Letourneur de la Manche. To complete the list, they added the names of 45 obscure persons, country justices, farmers, and even peasants. Thus there was nothing left to the Council of Ancients but the mere form of an election; and from the want of other qualified candidates, they were under the necessity of nominating to the office of directors the five persons at the head of the list presented by the Council of Five Hundred. The crafty Sieyes, however, who had been the adviser of all parties, but the [illegible] of none, did not yet think fit to venture [illegible] possession of power. He had disappro[illegible] the constitution which was now put in force [illegible] his own in opposition to it [illegible] by the Convention. [illegible] upon which [illegible] power [illegible] from their [illegible] being assigned, any of the public [illegible] they might appoint [illegible] having refused to accept [illegible] was elected in his stead. [illegible] the Council of Ancients was treated with [illegible] little more decency than formerly [illegible] of Cambaceres, a man of considerable [illegible] along with that of Carnot [illegible] by the Council of Five Hundred [illegible] little [illegible] the members of the Directory, with the exception of Reveillere Lepaux, had always belonged to the Mountain or most violent Jacobin party. As they now owed their power to that party, they employed its members in almost every official department. The goverment was therefore necessarily unpopular. Things might have been gradually altered, indeed, by successive elections, which would in time bring other men into power: But, by the forms of the constitution, the executive power was more permanent than the legislative body, without possessing any influence over it. Hence it was to be feared that a contest for power might speedily occur between a directory nominated by the Jacobin party and the new legislators appointed by the people, in which the Constitution might suffer shipwreck; an event which actually occurred.

239 The Council of Five Hundred outwits the Council of Ancients.

While the possession of power continued to fluctuate in the manner we have already stated, between the Moderate and the Jacobin or Mountain parties, the armies of the state were suffered to languish; but upon the credit

French Revolution, 1795.

credit of its former military success, the Republic was treated with respect by some of the neighbouring powers. On the 10th of April, a treaty of peace with Prussia, which had been negociated by the committees through the medium of Barthelemi the French resident at Basle, was presented to the Convention for ratification. By this treaty, it was stipulated, that the French troops should immediately evacuate the Prussian territory on the right bank of the Rhine, but should retain the territory belonging to that power on the left bank till a general peace. Prisoners of war were to be mutually restored, and the commerce of the two countries was to be placed on its ancient footing. Measures were also to be taken to remove the theatre of war from the north of Germany by treaties between France and those princes for whom the king of Prussia might interpose.

241 Treatment of the Revolution by foreign powers.

During the same month of April, the French Republic was acknowledged by the king of Sweden; and Baron Stael his ambassador was received at Paris with great solemnity. In the month of May a second treaty with Prussia was concluded. It chiefly regarded the line of neutrality. It is worthy of remark, that these [illegible] contained secret articles [illegible] committee. By [illegible] the Convention [illegible] [illegible] the example of Sweden [illegible] Republic. A [illegible] concluded at Basle [illegible] [illegible] territory of that country [illegible] She received [illegible] of the island of St Domingo [illegible] was included in this treaty [illegible] of the king of Spain [illegible] and the Italian [illegible] the Dauphin [illegible] XVI. died in the prison [illegible] been confined, along with [illegible] of his father, mother, and [illegible] was probably produced by disease [illegible] confinement, if not by [illegible] excited in the French nation such a degree of in[illegible] favour of his family, that the Convention found [illegible] to liberate his sister from imprisonment. The committee of public safety proposed to the Emperor to exchange this princess for the members of the Convention whom Dumourier had delivered up to Austria, along with two ambassadors, Semonville and Maret, who had been seized on their way to Turkey. This proposal was accepted, and the exchange took place at Basle in Switzerland.

243 Naval superiority of Britain.

On the side of Britain the war maintained its former character. The British retained their superiority by sea, and were unfortunate in their efforts on the continent. On the 14th of March the British fleet in the Mediterranean, under Admiral Hotham, engaged the French fleet, and took two sail of the line, the Ca-Ira and the Censeur; but as the French fleet, four days before the engagement, had captured the Berwick, a British ship of the line, when detached from the fleet, and as the Illustrious, another British ship of the line, was so severely injured in the action that she run ashore and was lost at Avenza, the substantial loss on both sides was nearly equal. On the 23d of June another British fleet under Lord Bridport attacked the French off Port L'Orient, and took three ships of the line, the rest of the fleet escaping into that port.

This evident superiority of the British fleet in every contest, induced the government to take advantage of the command which it had of the sea, to give assistance to the French Royalists in the western departments. These Royalists, hitherto unassisted by foreign powers, had, by repeated defeats, been reduced very low. The Convention had at last offered them a treaty, which was accepted and signed at Nantes on the 3d of March, on the one side by deputies from the Convention, and on the other by Charette, Sapineau, and other chiefs of the insurgents of La Vendée, and by Cormartin, as representing the party called *Chouans* or Night Owls. Stofflet, another chief, held out for some weeks longer; but at last, on the 20th of April, he too was under the necessity of submitting by treaty to the Republic.

244 Expedition to Quiberon Bay.

In a short time, however, the hopes of the Royalists were revived by the countenance of the British government, and these treaties were ill observed. In the beginning of June the British expedition was ready to sail for the French coast. The troops to be employed consisted of emigrants in the pay of Great Britain, and many of them had been prisoners of war, who now agreed to join the royal cause. The command during the voyage, and the selection of the place of landing, were intrusted to the Count D'Hervilly. The command on shore was given to Puisaye, who had been employed under the Girondists in the military service of the Republic, but had now become a royalist. The Count de Sombreuil was afterwards sent to join them with a small reinforcement.

On the 25th of June the expedition arrived in the Bay of Quiberon, and on the 27th 2500 emigrants made good their landing, after dispersing a small party of republican troops. The emigrant army soon after distributed itself into cantonments along the shore, and gave arms to the inhabitants of the country, who appeared to receive them with joy. It was soon found, however, that the Chouans, though well qualified for a desultory warfare, could not be of much use to regular troops. They had little subordination. They were easily dispersed, and never fought unless every advantage was on their side. When it was found that their unsteady aid could not be depended on, a resolution was taken to withdraw the emigrant army within the peninsula of Quiberon. The fort of that name was taken on the 3d of July. Its garrison consisted of five or six hundred men, and it was now occupied by the emigrants. A republican army, in the mean time, under General Hoche, advanced, and attacked all the posts that had been left without the peninsula. These were speedily taken. The emigrants and Chouans escaped into the boats of the British fleet, or fled under the cannon of the fort of Quiberon. The republicans then began to construct formidable works on the heights of St Barbe, at the entrance of the peninsula. To prevent their operations, a sally was made from the fort on the 7th of July; but without success. On the 15th, another sally was attempted in greater force. The whole

French Revolution, 1795.

whole troops in the peninsula amounted to about 12,000, including Chouans. Out of these a detachment of 5000 was sent to attack the heights of St Barbe. The republicans were entrenched in three camps. The two first of these were easily taken, and the detachment pressed eagerly forward to attack the third. But here a masked battery opened upon them with grape shot. A dreadful carnage ensued; and very few of the detachment could have escaped, had not the fire of the British ships soon compelled the republicans to desist from the pursuit.

245
Its failure.

It now became obvious that the expedition must ultimately fail. Desertion became extremely common among the emigrants. Those men in particular who had been prisoners of war, and received their liberty on condition of joining the expedition, seized every opportunity of going over to their countrymen; and a correspondence seems even to have been established between the republicans and the discontented troops in the fort of Quiberon. On the evening of the 20th of July, the weather was extremely tempestuous, which produced a fatal security in the emigrant army. Suspicious patroles were remarked; but as they repeated the watchword for the night, they were allowed to pass. The republican troops were conducted in silence along an unguarded quarter of the shore, till they were enabled to surprise one of the posts of the garrison, where they found the artillery men fast asleep. Their matches were seized, and the lanthorn intended to give the alarm to the British fleet was extinguished. The fort was speedily in confusion. Some regiments threw away their arms, and went over to the republicans; others even massacred their own officers. A considerable number, however, maintained a violent conflict for some time before they surrendered. Puisaye escaped on board the fleet. The Count de Sombreuil was taken; and this accomplished young man was soon after put to death, along with the other emigrant officers and all the Chouans that were found in the fort. The bishop of Dol was also put to death, with his clergy who accompanied him; but many of the private soldiers of the emigrant army made their peace with the republicans, by pretending they had been compelled to engage in the expedition.

The British fleet, with transports and troops, still hovered upon the French coast, and made an unsuccessful attempt upon the island of Noirmontier. In consequence of the season of the year, however, it returned home in December, after evacuating a small island called *L'Isle Dieu*, which the troops had for some time occupied.

246
Successes of the French in Germany.

On the side of Germany the fortress of Luxembourg surrendered on the 7th of June, after having been in a state of blockade since the preceding campaign. The French were now in possession of the whole left bank of the Rhine excepting the city of Mentz, which they attacked in vain, because the Austrians could at all times throw succours into it from Fort Cassel on the opposite bank of the river. Finding the capture of Mentz impossible in these circumstances, the French resolved to cross the Rhine, to invest the city on all sides. The enterprise, however, was delayed for some time, till the result of the British expedition to Quiberon should appear. In the month of August, General Jourdan forced the passage of the Rhine at Dusseldorf, at the head of what was called the army of the Sambre and Meuse. After driving before him three Austrian posts upon the Lahn, he crossed the Mein, and completely invested Mentz and Cassel. Pichegru, in the mean time, crossed the river, with the army of the Rhine and Moselle, near Manheim, of which city he immediately took possession. But the French generals soon found their forces inadequate to the undertaking in which they were engaged. A considerable detachment of Pichegru's army, after driving the Austrians under General Wurmser from a post of some importance, began to plunder, and went into confusion. The Austrians being informed of this circumstance, returned to the charge, and defeated the French. General Clairfait also, having violated the line of neutrality, came upon the rear of Jourdan's army, and took a considerable part of his artillery. Both the French generals now retreated. Jourdan was rapidly pursued by Clairfait till he returned to Dusseldorf, where he maintained his ground. Pichegru recrossed the Rhine near Manheim, leaving a garrison of 8000 men in that city. The Austrians advanced in all directions. Manheim was taken after a vigorous siege. The French were driven from the neighbourhood of Mentz. The Palatinate became the theatre of war, and the Austrians seized the country called the *Hundsruck*, south of the Rhine as far as Landau and Treves. After various engagements, in which little more ground was lost or won, the two parties entered into an armistice for three months.

247
They receive a check.

On the 28th of August a treaty of peace was concluded between the French Republic and the Landgrave of Hesse Cassel, on condition that he should send no more troops to Great Britain for the prosecution of the war. It is not a little singular, that peace was concluded with the Elector of Hanover at this period upon similar terms. The Duke of Wirtemberg, and some other princes of the empire, also began to treat; but the negociations were broken off in consequence of the reverse of fortune now experienced by the French.

The Directory, however, resolved to continue the war with vigour, and vast preparations for the approaching campaign were made during the winter. The Mountain party being once more possessed of power, its members exerted themselves with their usual energy. Such, however, was the turbulent character of these men, that they could not long submit peaceably to any government, and soon became weary of that Directory whom they themselves had established. They held clubs in all quarters, and were continually disturbing the public tranquillity. For some time the government supported them. The Parisians, after the 5th October, no longer dared to avow openly their dislike to the Jacobins; but they were understood to express this sentiment by wearing green silk cravats, and by applauding with much vehemence at the public spectacles the air called *Le Reveil du Peuple*. The Directory now prohibited, by an edict, as tokens of royalism, the wearing of green cravats, or the performing at any of the theatres the air now mentioned, though the sentiments it contained were entirely republican. The Directory also ordered in its stead, that the Marseillois hymn, and other popular songs, should be performed every evening at all the theatres. The Parisians shewed their disapprobation of the Directory by maintaining a profound silence during the performance of these songs,

249
Ridiculous conduct of the Directory.

French Revolution 1796.

songs, which had never failed till that period to excite bursts of applause. The Directory soon became ashamed of this ridiculous contest, and in a few weeks recalled their edict. Indeed they found it impossible to give countenance for any long period to the restless and innovating spirit of the Jacobins, who continually wished and attempted to return to revolutionary, that is, to violent measures against their antagonists. In the south, in particular, the present supremacy of the Jacobins produced very pernicious effects. Freron, who had deserted them after the death of Robespierre, and became one of their most violent adversaries, thought fit to return to their party before the 5th October, and was sent to Toulon with full powers of administration. Here he dismissed the municipality that had been elected by the people, restored the Jacobin clubs, and proceeded to imprison all suspected persons as in the days of Robespierre. These measures produced a violent reaction on the part of the enemies of the Jacobins. Assassinations became frequent, and many persons began to leave the country. The Directory was alarmed by the many complaints against the Jacobins or terrorists that came from all quarters, and resolved to aim at popularity by deserting a set of men who could not be prevailed upon to act with moderation. Freron was recalled from Toulon, and more manageable men were sought out to replace the more violent Jacobins, who were in general dismissed from the service of government.

250 Measures taken against the Jacobins.

The Directory proceeded farther, and acknowledged, by a public resolution, that its confidence had been abused. The minister of police was ordered to remove from Paris the members of former revolutionary tribunals, and others who now acted as leaders of the Jacobins, or *anarchists* as they were called. A body of troops, amounting to 10,000 men, called the *legion of police*, that had acted against the Parisians on the 5th October, and was now devoted to the Jacobins, was ordered by the Directory, with the authority of the legislature, to join the armies on the frontiers. These men refused to obey the order; but they were reduced to submission by some troops that had been brought to the neighbourhood to provide against such an event. The more violent Jacobins were enraged, but not intimidated, by these measures, and began to organize a plot for the overthrow of the Directory and of the majority of the councils, who had now deserted them. They were not prepared for action, however, before the month of May, and by that time their designs were discovered and counteracted. On the 10th of that month the guards were increased, and bodies of cavalry stationed around the Luxembourg and the Thuilleries. The Directory at the same time informed the Council of Five Hundred, by a message, that a dreadful conspiracy was prepared to burst forth on the following morning. At the sound of the morning bell, which is every day rung, the conspirators were to proceed in small parties of three or four men to the houses of such persons as they had marked out for destruction. After assassinating those persons, the whole parties were to unite, and to act against the Directory, whose guard they apprehended they could easily overpower. The conspirators had appointed a new Directory and a new legislature, to consist of the most violent of their own party. Among the leaders of this conspiracy, who were now arrested by order of the Directory, was Drouet the postmaster of Varennes, whom we formerly mentioned as having arrested the unfortunate Louis XVI. when attempting to escape to the frontiers. Along with him were Babeuf, Antonelle, Pelletier, Gaudet, Julien, General Rossignol, Germain, D'Arthe, Laignelot, and Amar, who had been a member of the committee of general safety along with Robespierre. Vadier and Robert Lindet were also engaged in the conspiracy, but they made their escape. Drouet also escaped by the connivance of the Directory, as was generally understood; but the rest of the conspirators were removed for trial to the high national court at Vendome, where they were condemned. At the period of their removal thither, a new attempt was made by their party for their rescue. About 600 men entered the camp at Grenelle near Paris, and endeavoured to prevail with the soldiers to join them in an insurrection. This attempt was altogether unsuccessful. A few of the insurgents were killed, and the rest fled.

251 Moderate party.

These defeats of the Jacobins, and the discredit under which they were again brought, encouraged the moderate party in the two legislative councils to attempt to repeal the last decrees of the Convention, which had at once granted them an amnesty, and confirmed all the laws which, by confiscating the property of emigrants, excluded their relations from the succession. The discussion lasted many days; but the result was, that the law with regard to emigrants remained on the former footing; and the only point which the moderate party were yet able to carry was a modification of the decree to this extent, that those terrorists were declared incapable of holding public offices who owed their safety to the amnesty.

252 Distressed state of the finances.

The state of the finances now began to occupy the French government in a very serious manner. During the government of Robespierre, while the credit of the assignats was preserved by the influence of terror, or by the sale of the church lands, and the property of emigrants, little attention was bestowed upon this subject. When money was wanted, more assignats were fabricated; and as few or no taxes were demanded from the people, no enquiry was made about the public expenditure. But when the boundless extravagance of the agents of government had loaded the circulation with assignats till they became of little or no value, it became a very difficult question how the public service was hereafter to be supported. A new paper currency, called *rescripts*, was first adopted. These were orders on the treasury for cash, payable at certain periods. But their credit soon passed away, as the treasury had no means of fulfilling its engagements. The Directory complained very bitterly, in a message to the Councils, of its distresses, and of the want of funds to carry on the approaching campaign. In consequence of this message, a law was passed, on the 25th of March, authorising the sale of the remainder of the national domains for the price that had been fixed upon them at an early period of the revolution, amounting to about twenty-two years purchase. A new paper currency, called *mandats*, was to be received in payment. But the credit of government was now gone. The mandats instantly lost in all private transactions one-fourth of their value, and they soon fell still lower. This, however, produced a great demand for national pro-

 perty,

French Revolution, 1796.

perty, which was thus about to be sold far below its value. To prevent this effect, the legislature broke its engagements, and decreed, that one-fourth of every purchase should be paid, not in mandats, but in cash. This decree put a stop both to the sale of national property and to the circulation of mandats.

253 Reasons of the flourishing state of agriculture.

Recourse was next had to taxation; but this was attended with much difficulty. By the war, and the violent government of Robespierre, the French commerce had been in a great measure ruined. Industrious men, who possessed any capital, had therefore turned their attention to the cultivation of land. Many circumstances led to this. By the emigration of the nobles, and the confiscation of the church lands, the farmers were left with no landlord but the government; which, being supported by assignats, paid little attention to any other source of revenue. Hence they paid no rent, and speedily rose into opulence. The revolutionary government, which kept the inhabitants of the towns under dreadful bondage, was scarcely felt by the inhabitants of the country, who thus enjoyed the advantage of exciting no suspicion in the rulers, and of paying neither rent nor taxes. The law which declared assignats to be a legal tender of payment, was a great source of profit to the cultivators of the soil. They contrived to sell the produce of their farms only to such as offered them ready specie; while, at the same time, they paid their rents, where the landlord had not emigrated, in assignats, which they obtained at a trifling price. Hence it usually happened, that while the tenant enjoyed affluence, his miserable landlord was reduced to the necessity of selling his moveables to buy a portion of the grain that grew upon his own estate, or was tempted to sell the estate itself, at an undervalue, to obtain the means of emigration. [illegible] and other circumstances, the whole industry of the French nation came to be directed towards agriculture. Their country was accordingly well cultivated; but as the riches of agricultural nations are not easily subjected to taxation, the French Directory now found it impossible to carry on the schemes of ambition and of conquest, which they had already formed, without relying for resources upon the plunder of the neighbouring states, which speedily rendered their armies odious in all those quarters of Europe to which they penetrated.

254 National Institute.

Amidst their preparations for the approaching campaign, the Directory attempted to increase their own reputation at home, by establishing what is called the *National Institute*; which is a society of men of letters, under the protection of the government *. Into this body were collected the most celebrated literary characters in the nation that had escaped the fury of the Mountain Party. Among these were La Place, Lalande, Fourcroy, Bertholet, Volney, Dolomieu, and others, well known throughout Europe. The first public meeting of the Institute was held, with great splendour, on the 4th of April, in the hall of the Louvre, called the *Hall of Antiques*. The ambassadors of Spain, Prussia, Sweden, Denmark, Holland, America, Tuscany, Genoa, and Geneva, were present. The members of the Directory attended in their robes, and their president made a speech of installation, declaring the determination of the executive power to protect and encourage literature and the arts. Dusaulx, the president of the Institute, replied, in a speech in which he declared the resolution of the members to labour to give lustre to the republican government by their talents and productions. Fifteen hundred spectators applauded the speeches with enthusiasm, and vainly imagined that all the evils of the revolution were terminated, and that their country was now entering upon a career of unexampled glory and prosperity.

* See INSTITUTE, *Suppl.*

255 Overtures of the British government

At this period the British government made an approach towards a negociation with France. On the 8th of March Mr Wickham, the minister plenipotentiary to the Swiss Cantons, transmitted to Barthelemy, ambassador from the French Republic to the Helvetic body, a note containing three questions. Whether France would be disposed to send ministers to a congress to negociate peace with his Britannic Majesty and his allies? Whether France would be disposed to communicate the general grounds on which she would be willing to conclude peace, that his Majesty and his allies might consider them in concert? and, lastly, Whether France would desire to communicate any other mode of accomplishing a peace? The note concluded with a promise to transmit to the British court whatever answer should be returned; but declared, that Mr Wickham was not authorised to enter into any discussion upon these subjects.

256 Insolently rejected by the Directory.

On the 26th of the same month Barthelemy returned an answer in name of the French Directory. This answer began by complaining of insincerity in the proposal made by the British court, seeing its ambassador was not authorised to negociate, and that a congress was proposed, which must render negociation [illegible]. It proceeded to state the ardent desire of the D[illegible] for peace; but asserted, that it could listen [illegible] posal for giving up any territory that [illegible] by the constitutional act to form a part [illegible] (alluding to the Austrian Netherlands) [illegible] however, that other countries occupied [illegible] armies, and political or commercial inte[illegible] come the subject of negociation. [illegible] the Directory declared its readiness [illegible] proposals.

To this answer no reply was sent; [illegible] court published a note, of which copies [illegible] to the foreign ministers residing at London [illegible] the spirit of the Directors answer [illegible] and also the refusal even to negociate about the [illegible] of foreign territory, under pretence of an internal regulation. It was added, with truth, that while such dispositions were persisted in, nothing was left but to prosecute a war equally just and necessary; but that, when more pacific sentiments should be manifested, his Majesty would be ready to concur with his allies in taking measures for establishing a just, honourable, and permanent peace.

257 French armies.

The French Directory had succeeded, during the winter, in reducing the western departments into subjection. The emigrant expedition from England had induced the royalists once more to try the fortune of war; but, after various defeats, their leaders, Charette and Stofflet, were taken, and put to death on the 29th of March, and the insurgents were suppressed in all quarters. The French government being thus left without an enemy at home, was enabled to make great efforts on the frontiers. The military force of the Republic was divided into three armies. On the Lower Rhine, the army of the Sambre and Meuse was chiefly stationed about Dussel-

French Revolution, 1796.

Duſſeldorf and Coblentz, and was commanded by Jourdan. Moreau commanded the army of the Rhine and Moſelle, in the room of General Pichegru, who had been diſmiſſed from his command. This army was ſtationed on the Upper Rhine, and from Landau to Treves. The third and laſt army was ſtationed on the coaſt of Italy, from Nice towards Genoa, and now received Bonaparte as its commander. The name and the actions of this man muſt hereafter fill ſo large a ſpace in the detail of this eventful period, that it is neceſſary to pay ſome attention to his perſonal hiſtory.

258 Bonaparte

A Corſican gentleman, a lawyer by profeſſion, but who had appeared in arms under the celebrated Paoli in defence of the independence of his native iſland, was the father of Napolone Bonaparte. Napolone was born at Ajaccio in 1767; and by the intereſt of M. de Marboeuf, the French governor of the iſland, he was placed for his education at the celebrated military academy of France (*Ecole Militaire*), which has produced ſo many accompliſhed men. At a very early period of life he preſented himſelf as candidate for a commiſſion in the artillery, and was ſucceſsful, being the 12th on the liſt out of 36 victorious candidates. In conſequence of this event he ſerved two or three years in the French army as a lieutenant in the regiment of La Fere. Bonaparte having riſen to the rank of captain of artillery, returned to Corſica after the revolution, and was there elected lieutenant-colonel of a corps of Corſican national guards. Here he formed a connection, which had nearly proved fatal to him, with General Paoli, the friend of his father. He reſented the treatment which [illegible] from Robeſpierre's government, and en[illegible] into his intereſts as to write the remon[illegible] which was tranſmitted by the municipality to the Convention, againſt the decree which declared the [illegible] enemy to the Republic. In conſequence of [illegible] was at one time iſſued for his arreſt by [illegible] of the Convention. He made his [illegible] however, on this occaſion; and reſolved to ad[illegible] to the intereſts of France, in oppoſition [illegible] at this period formed [illegible] of Corſica. He embarked with the [illegible] of his family for France, and arrived [illegible] time when Lord Hood was in poſſeſſion [illegible] Saliceti, a deputy from Corſica to the Convention, introduced him to Barras, who was now ſuperintending the ſiege of Toulon. Here Bonaparte was advanced to the rank of general of artillery; and, under Dugommier, directed the attack of the various fortified poſts around the city. He was afterwards employed for a ſhort time againſt the royaliſts in the weſt of France; and we have already mentioned, that he was at the capital, and aſſiſted Barras in the conteſt between the Convention and the Pariſians on the 5th October. Hence he was regarded with diſlike by the moderate party, and repreſented as an unprincipled adventurer, brought forward to ſupport the terroriſt faction. He had many enemies, therefore, at the commencement of his career, and his character was treated with much freedom. The ſcandal of the times went ſo far as to aſſert, that he owed his preſent preferment, not ſo much to any talents he had yet had an opportunity to diſplay, as to his marriage with Madame Beauharnois, a beautiful French woman whom Barras had taken under his protection.

259 Takes the command of the army of Italy.

The French army of Italy amounted at this time to 56,000 men. Bonaparte at his arrival found it ill equipped, and the troops mutinous for want of pay and neceſſaries. He addreſſed them, however, in the true ſtyle of military enterpriſe, "If we are to be vanquiſhed, we have already too much; and if we conquer, we ſhall want nothing;" and ordered them to prepare for immediate action. His opponents, however, anticipated him in the attack. The Auſtrians employed in the defence of Italy, under General Beaulieu, are ſaid to have more than equalled the French in numbers. To theſe were united the King of Sardinia's army, under Count Colli, of 60,000 regular troops, beſides the militia of the country, which was now embodied, and a ſmall body of Neapolitan cavalry, amounting to about 2500 men. General Beaulieu began the campaign, on the 9th of April, by attacking a poſt called Voltri, which the French poſſeſſed, within ſix leagues of Genoa. They defended themſelves till the evening, and then retreated to Savona. Next morning Beaulieu, at the head of 15,000 men, preſſing upon the centre of the French army, was completely ſucceſsful till one o'clock afternoon, when he reached a redoubt at Montenotte, which was the laſt of their entrenchments. This redoubt contained 1500 French. Their commander, Rampon, prevailed with them, in a moment of enthuſiaſm, to ſwear that they would not ſurrender; and the conſequence was, that they arreſted the progreſs of Beaulieu for the remainder of the day. During the night, Bonaparte ſtationed his right wing under La Harpe, a Swiſs exile, in the rear of the redoubt of Montenotte, which ſtill held out, while he himſelf, with Maſſena, Berthier, and Salicetti, advanced by Altara, to take the Auſtrians on their flank and rear. Beaulieu, in the mean time, had received powerful reinforcements, and on the morning of the 11th renewed the attack on the French under La Harpe; but Maſſena ſoon advancing upon the flank of the Auſtrians and Sardinians, they gave way on all ſides. Two of their generals, Roccavina and Argentau, were wounded. They loſt 2500 priſoners, and were purſued beyond Cairo, of which the French took poſſeſſion on the following day.

260 His ſucceſs.

On the 13th at day-break, the defiles of Milleſimo were forced by the French General Augereau; and, by a ſudden movement, General Provera, a knight of the order of Maria Tereſa, at the head of 1500 Auſtrian grenadiers, was ſurrounded; a circumſtance which proved not a little embarraſſing to the French army. For this reſolute officer, inſtead of ſurrendering, inſtantly withdrew to a ruined caſtle on the top of the mountain, and there entrenched himſelf. Augereau brought up his artillery, and ſpent many hours in attempting to diſlodge him. At laſt he divided his troops into four columns, and endeavoured to carry Provera's entrenchments by ſtorm. The French loſt two generals, Banel and Quenin, and Joubert was wounded in this attempt, which proved unſucceſsful. Provera paſſed the night in the midſt of the French army, which had been prevented by his obſtinate reſiſtance from coming to battle. On the 14th the hoſtile armies faced each other, but a diviſion of the French troops was ſtill occupied in blockading General Provera. The Auſtrians attempted to force the centre of the French, but without ſucceſs. Maſſena, in the mean time, turned the left flank of their left wing near the village

French Revolution 1796.

village of Dego; while La Harpe, with his division in three close columns, turned the right flank of the same wing. One column kept in awe the centre of the Austrians, a second attacked the flank of their left wing, while the third column gained its rear. Thus was the left wing of the combined army completely surrounded and thrown into confusion. Eight thousand men were, on this occasion, taken prisoners, and General Provera at last also surrendered.

These victories were not gained over a timid or an inactive adversary. On the morning after his fatal defeat at Millesimo, Beaulieu made one of those spirited efforts which often retrieve and alter the fortune of war. At the head of 7000 chosen Austrian troops he attacked, at day-break, the village of Dego, where the French reposed in security after their success. He took the village; but the French having rallied under General Massena, spent the greater part of the day in attempting to retake it. They were thrice repulsed, and one of their generals, Causse, was killed. Towards evening, however, Bonaparte in person having brought up reinforcements, the post was retaken, and the Austrians retired with the loss of 1400 made prisoners.

Bonaparte had now thrown himself between the Austrian and Sardinian armies. By the possession of the strong post of Dego, his right was secured against the efforts of Beaulieu, while he was enabled to act with the mass of his force against the Piedmontese troops. His enterprises in this quarter were facilitated by the exertions of Augereau, who had opened a communication with the valley of the Tanaro, where Serrurier's division was approaching the town of Ceva, near which the Piedmontese had an entrenched camp defended by 8000 men.

On the 16th Augereau attacked the redoubts which covered this camp, and took most of them; which induced the Piedmontese to evacuate it during the night, and on the 17th Ceva was entered by Serrurier. Count Colli now retreated to cover Turin; making choice, however, of the strongest posts, and fighting in them all. He was able, on the 20th, to repulse Serrurier; but on the 22d Bonaparte, still pressing on the Piedmontese general, defeated him near Mondovi, and entered that place. The retreating army next endeavoured to make a stand, with its head quarters at Fossano, and its wings at Coni and Cherasco. On the 25th Massena advanced against Cherasco, which was speedily evacuated. Fossano surrendered to Serrurier, and Alba to Augereau.

261 Armistice with Sardinia succeeded by

Previous to these last movements, however, Count Colli, on the 23d of April, had written to Bonaparte, requesting an armistice, to allow the King of Sardinia an opportunity of negociating a peace. The French army was now within 26 miles of Turin; and that prince saw himself suddenly reduced to the necessity of standing a siege in his capital, or of accepting such terms as the conqueror might think fit to impose. Bonaparte granted an armistice; on condition that the three fortresses of Coni, Ceva, and Tortona, should be delivered up to him, with their artillery and magazines, and that he should be allowed to cross the Po at Valentia. The armistice was signed on the 29th, and it was followed by a formal treaty with the French Republic, which was concluded at Paris on the 17th of May. The conditions imposed by this treaty upon

262 A formal treaty.

the King of Sardinia were humiliating and severe. He gave up to France for ever the duchy of Savoy, and the counties of Nice, Jenda, and Bretueil. He gave an amnesty to all his subjects that were prosecuted for political opinions. He agreed that the French troops should have free access to Italy through his territory; and, in addition to the fortresses surrendered by the armistice, he gave up those of Exiles, Susa, Brunette, Assiette, Chateau Dauphin, and Alexandria, to be possessed by the French during the war; and they were authorised to levy military contributions in the territory occupied by them. He agreed to erect no fortresses on the side of France, to demolish the fortresses of Brunette and Susa, and to disavow his disrespectful conduct towards the last French ambassador.

In the mean time the French army advanced towards the Po. Beaulieu was deceived by the article in the armistice; which stipulated, that the French should be allowed to cross that river at Valentia, and made all his preparations for resistance in that quarter. Bonaparte laboured, by several evolutions, to confirm this error; and while the Austrian general waited for him near Valentia, in various well fortified positions, he advanced hastily into Lombardy, and had proceeded sixty miles down the river to Placentia, where he arrived on the 7th of May, before the direction of his march was discovered. He immediately seized whatever boats or other craft he could find, and effected his passage without difficulty, there being only a small party of Austrian cavalry accidentally on the opposite bank, and they fled at his approach. Beaulieu in the meanwhile had sent, when too late, a body of 6000 infantry and 2000 cavalry, to prevent if possible the French from passing the river; but Bonaparte, now on the same side of the river with themselves, met and defeated them on the 8th at the village of Fombio. Another body of 5000 Imperialists, advancing to the assistance of [illegible] Fombio, was met at Codogno, and repulsed by General La Harpe; but this officer was killed on the occasion. On the 9th Bonaparte granted an armistice to the Duke of Parma, on condition of his paying a contribution of 2,000,000 of French money, and delivering [illegible] quintals of wheat, 5,000 quintals of oats, and [illegible] oxen, for the use of the army. This prince also agreed to deliver up 20 of his best paintings, to be chosen by the French. This last stipulation was no sooner known in France, than many men of letters and artists remonstrated against it as both impolitic and useless. They contended, that it would render the French Republic odious to all Italy, without producing any advantage to compensate this evil, as the progress of the arts could not be promoted by removing their best productions from the scenes in which they originated. But the Directory was too much occupied by views of national aggrandisement to listen to considerations of this kind, and similar stipulations were ordered to be inserted in every future treaty; by which means the most valuable curiosities of Italy were gradually transferred to the French capital.

Beaulieu, now driven from the Po, crossed the Adda at Lodi,* Pizzighitone, and Cremona. He left some troops, however, to defend the approaches to Lodi. The advanced guard of the French attacked these on the 10th, and drove them into the town; which was entered in such close pursuit, that the Imperialists, on leaving

French Revolution, 1796.

ving it, had not leisure to break down the bridge over the Adda. At the other end of the bridge the Imperial army was drawn up, and thirty pieces of cannon defended the passage. The French generals, after a consultation, agreed that it could not be forced. But Bonaparte having demanded of his grenadiers if they were willing to make the attempt, they applauded the proposal, and he formed them into a close column. Taking advantage of a cloud of smoke which issued from the hostile artillery, they rushed along the bridge, which was about 100 yards in length, and were at the middle of it before they were discovered. Here a general discharge from the Austrians destroyed 700 men. The French column hesitated, and the carnage became terrible; but Massena, Berthier, Dallemagne, Cervoni, Lasnes, Dupat, and other officers, flying to the head of the column, urged on the soldiers, and pressing forward, broke into the ranks of the Imperial army, which immediately gave way, and fled in all directions. This exploit has been much celebrated. The intrepidity of the troops by whom it was accomplished is unquestionable; but how far the leader who urged them to such an enterprise is entitled to approbation may well be doubted. He had passed the Po with scarcely the loss of a man. The Adda is a very inferior stream, which has fords both above and below the town of Lodi. The river was actually crossed at one of these by Augereau with the cavalry, during the attack upon the bridge. With the delay of one day therefore the passage might have been effected without difficulty by the whole army, and there was no adequate motive to justify the lavish expenditure of blood which was here made; for the French army no longer pressed forward in pursuit of Beaulieu, but, after the surrender of Pizzighitone and Cremona on the 13th, returned upon Pavia and Milan [illegible] (A). These places opened their gates without [illegible] though the citadel of Milan held out for a [illegible].

It would seem that, in the original plan of Bonaparte's campaign, the utmost expected from his efforts [illegible] such an ascendancy in Italy as might induce the [illegible] princes and states of that country to desert the coalition against France, which all of them assisted with money and provisions, if not with troops. To accomplish this object, though he sent Massena in pursuit of Beaulieu as far as Verona, yet he himself now turned aside into Modena and the territories of the Pope. He took Ferrara, Bologna, and Urbino; and at last granted an armistice to his holiness and the Duke of Modena, on the usual conditions of large contributions of money, paintings, and curiosities. From the Pope he farther exacted the cession of the legations of Bologna and Ferrara, and possession of the citadel of Ancona. His march into the Roman territory so alarmed the Neapolitan cabinet, that it now solicited peace; and Bonaparte granted an armistice, without attempting to add to it the humiliating conditions to which the other Italian states were subjected. From the territories of the Pope, Bonaparte hastily advanced with a body of troops to Leghorn, in the neutral state of Tuscany, under pretence of driving out the English, whose property there he confiscated. By these measures the task assigned to Bonaparte was completed by the time the campaign upon the Rhine was begun. Mantua was still indeed in the hands of the Imperialists, but it was blockaded, and all Italy was now submissive to France.

French Revolution, 1796. 166 Successes of the French in Germany.

To diminish, if possible, the efforts of the French on the side of Italy, the Imperialists thought it necessary to renew the contest in Germany. An intimation was therefore sent to General Jourdan, that the armistice would terminate and hostilities commence on the 31st of May. At this time General Wartensleben opposed Jourdan; and the Archduke Charles commanded the army in the Hundsruck, which covered Mentz and Manheim, and was stationed against Moreau on the Upper Rhine. The French began their operations with a very artful stratagem, intended to draw the whole Austrian force to the Lower Rhine, that Moreau might have an opportunity of suddenly penetrating into Swabia, and consequently of carrying the war towards the hereditary territories of Austria. For this purpose Moreau remained quiet, while Jourdan began to act vigorously. On the 31st of May his left wing, under Kleber, issued from the lines of Dusseldorf, on the right bank of the Rhine, and, advancing towards the Sieg, defeated the Imperialists. Thereafter they were driven successively from the strong positions of Ukareth and Altenkirchen, and retreated across the Lahn. Jourdan, in the mean time, having advanced with his centre and right wing, forced the Austrian posts on the Nahe, crossed the Rhine, formed the blockade of the fortress of Ehrenbreitstein, and hastened forward as if about to form the blockade or siege of Mentz. By these movements the Archduke found himself in the hazardous situation of having Moreau in his front, while Jourdan, with a victorious army, commanded his rear. He therefore hastily crossed the river, leaving the fortresses of Mentz and Manheim to keep Moreau in check. Having joined the retreating army, he encountered Jourdan's advanced guard, which he compelled to retire after an obstinate conflict. Jourdan did not hazard a general engagement, but withdrew to his former positions, the Archduke pressing hard upon him, till he raised the blockade of Ehrenbreitstein, and crossed the Rhine in its neighbourhood, till Kleber, on the 20th of June, entered the lines of Dusseldorf, from which he had set out.

These movements were foreseen. For the instant that the Archduke withdrew from the Palatinate to drive Jourdan down the Rhine, Moreau ascended rapidly towards Strasburg; so that these hostile armies seemed to be flying from each other with all possible speed. On the 24th of June, Moreau effected the passage of the river opposite to fort Kehl. This was an enterprise of considerable difficulty; for a sudden swell, by covering a part of the islands with which the river abounds, had prevented the Austrians from being taken by surprise, as was originally intended. The entrenchments on such islands as were occupied by troops were speedily carried by the bayonet, and 2600 French landed on the opposite shore, but without cavalry or artillery. Here they were exposed to the attacks of the Austrian

(A) We think this conduct cannot be accounted for, but by the supposition of a very improper correspondence between Bonaparte and the Austrian officers.

French Revolution, 1796.

Austrian horse from the camp of Wilftedt, and to the fire of the cannon of the fort. They maintained their ground, however, and even acted on the offensive, till the boats, which had been sent back, returned with a reinforcement. The whole redoubts and the fort were then instantly taken by storm, or with the assistance of such cannon as had been found in the first redoubts at which the French arrived, and the Imperialists fled towards Offenburgh.

The departure of the Archduke to the Lower Rhine in pursuit of Jourdan, and the large detachments which had recently been sent towards Italy to oppose Bonaparte, now enabled Moreau to enter Swabia with a great superiority of force. The strong military positions, however, which the country affords, presented to him considerable difficulties. On the 26th of June he drove the Austrians from their camp of Wilftedt: and on the 27th he advanced with his army, in three columns, against another camp of 15,000 men in front of Offenburg. General Wurmser sent a strong reinforcement from Manheim to the assistance of these troops; but having encountered two of the French columns on its way, the reinforcement was defeated, and the camp at Offenburg was evacuated during the night. The Austrians made an obstinate stand at Renchen, near Philipsburg, on the 29th, but were at last compelled to retire with the loss of 1200 men taken prisoners, and several pieces of cannon. On the 2d of July a division of the French army, under General Laroche, succeeded in seizing the mountain Knubis, which is the highest point of the ridge of mountains called the Black Forest. On the 3d, after an obstinate conflict, the Austrians were driven from the pass of Friedenstadt; in consequence of which they lost all communication with the emigrant troops under the Prince of Condé, and other Imperial troops stationed on the Rhine towards Switzerland. On the 6th, the left wing of the French, under Desaix, encountered the Imperialists at Rastadt, where the Austrians, who had received some reinforcements from the Lower Rhine, made a very determined resistance; but were at last compelled to give way, and to retire to Ettingen.

The Archduke Charles now arrived in person with his army from the Lower Rhine, where he had left Wartensleben, but with inferior force, to oppose Jourdan. The French, under this general, had instantly resumed the offensive upon the departure of the Archduke. Kleber advanced from the lines of Dusseldorf, as formerly; while the centre and right wing crossed the Rhine near Coblentz. The posts of Ukareth and Altenkirchen were forced, and on the 9th of July the whole of Jourdan's army crossed the Lahn. On the 10th, Wartensleben was defeated near this river, after great slaughter on both sides, with the loss of 500 prisoners; and the French on the 12th entered Franckfort. The situation of the hostile armies was now become extremely important. The two Imperial armies were at no great distance from each other, and were placed in the centre between the armies of Moreau and Jourdan. Could the Archduke, who was commander in chief, have resisted one of these armies for a short time, at any strong position, by a detachment of his troops, while he precipitated himself with the mass of his force upon the other, it is probable that any farther invasion of Germany might have been prevented. But the activity of the French generals, whose progress could nowhere be resisted by partial efforts, prevented the possibility of executing such a plan. He was therefore under the necessity of making his final exertion for the present safety of Germany against Moreau at Ettingen, on the 9th of July, without having formed any junction with Wartensleben. The battle was most obstinately fought. The French were four times repulsed in their attempts to force the heights of Rollensolhe; and it was not till they had experienced a dreadful slaughter that they at last carried the field by the bayonet.

The loss of the battle of Ettingen compelled the two Imperial armies to retire eastward. After placing strong garrisons in Mentz, Manheim, and Philipsburg, the Archduke retreated through Swabia towards Ulm, where his magazines were placed. At every strong position, however, he made an obstinate stand; thus endeavouring to render the progress of the French under Moreau as tardy as possible. Wartensleben, with the other Imperial army, retired through Franconia, resisting Jourdan in the same manner. Many bloody battles were fought, of which it is here unnecessary to give a minute description. It is sufficient to remark, that the French were long successful in them all. They gradually pressed forward till Moreau's army compelled the Archduke to cross the Neckar, and afterwards the Danube, leaving the whole circle of Swabia in the rear of the French. Wartensleben was in like manner driven through Aschaffenburg, Wurtzburg, Schweinfurt, and found it necessary to cross the Rednitz, on the [illegible] of August, at Bamberg, to avoid the pressure of [illegible] army in his rear. This army [illegible] its right wing, under Bernadotte, [illegible] march, with his advanced posts [illegible] body of the army had driven [illegible] the Nab, and had reached Amberg [illegible] August.

Excepting a part of the mountains [illegible] French armies under Jourdan, [illegible] and [illegible] the whole [illegible] the [illegible] of Bohemia to the [illegible] alarm throughout Germany was extreme [illegible] of Wirtemberg obtained peace from the [illegible] dition of paying [illegible],000,000 of French money [illegible] circle of Swabia did the same, on engaging [illegible] 12,000,000 of livres, and to deliver 8,400 horses, [illegible] oxen, 100,000 quintals of wheat, 50,000 quintals of rye, 100,000 sacks of oats, 100,000 pairs of shoes, and a large quantity of hay. The Margrave of Baden obtained peace on similar terms. The elector of Bavaria and the circle of Franconia negociated, and offered large payments; and even the diet of Ratisbon sent a deputation to treat with the French generals for neutrality. The King of Prussia now entered into a new treaty with the French; the conditions of which were concealed, but its nature appeared in the advantage which he took of the progress of their arms to take possession of certain territories in Germany, and particularly of the suburbs of Nuremberg, under pretence of some antiquated title. Spain also entered into a treaty offensive and defensive with France, which was afterwards followed up by a declaration of war against Britain.

268 Danger of the house of Austria.

The danger of the house of Austria was now very great; and had Bonaparte, instead of being detained in Italy, by events of which we shall immediately take notice,

French Revolution, 1796.

tice, been able to cross the Tyrol by Inspruck, and to reach the banks of the Danube, there is little doubt that the Emperor must have submitted to such conditions as the French thought fit to impose. Deserted in all quarters by the members of the coalition, he still, however, retained an ally in Great Britain, whose riches, liberally bestowed in the form of a loan, extricated him from the present difficulties. Having the command of abundance of money, he was enabled to send one army after another to oppose Bonaparte in Italy, while he recruited his armies in Germany by extensive levies, and by taking into his pay the troops of those states that made peace with France.

269
Masterly conduct of the Archduke.

The Archduke, having received powerful reinforcements, resolved to make a stand, on the 11th of August, against Moreau at Umenheim. A severe battle was fought during seventeen hours, and one of the wings of the Austrian army, under General Riese, even succeeded in occupying four leagues of territory in the rear of the French army; but the Archduke having received intelligence, in the mean time, that Wartensleben could not maintain his ground against Jourdan, he thought it necessary to continue his retreat, and to adopt new measures. On the 17th of August he left General La Tour, with a part of his numerous army, to oppose Moreau, and having crossed the Danube at Neuburg and Ingolstadt, he marched to Wartensleben's assistance to fall upon Jourdan with united forces. On the 22d he attacked Bernadotte at Teining, and forced him to retire towards Nuremberg. The Archduke was thus upon the right of Jourdan, while Wartensleben was [illegible] his front. The French general, finding his [illegible], began to retreat on the 24th. From [illegible] the finances, the French armies, at the commencement of this campaign, had been extremely ill [illegible] and ill paid. Hence the two armies of Moreau and Jourdan plundered, without decency or mercy, [illegible] places into which they entered. In Jourdan's [illegible] more especially, the want of discipline was ex[illegible] (A). Hence, when they began to retreat, loaded [illegible] with spoil, they suffered no less from the [illegible] inhabitants of the countries through which they passed, than from the military efforts of the hostile army. The Archduke having joined Wartensleben, was enabled to [illegible] off Nauendorf with reinforcements to La Tour, who opposed Moreau, and, in the mean time, he continued in person to pursue Jourdan towards Wurtzburg. Here the French made a stand, on the 3d of September, and a general engagement took place. Both parties suffered great loss, but more especially the French, who retreated during the night. Jourdan now fled by Fuldaw to Wetzlaer. Having crossed the Lahn, where he made some resistance, he descended along the banks of the Rhine, till his army, on the 17th, reached Coblentz and Dusseldorf, from which it had originally departed.

270
Critical situation of Moreau.

The situation of Moreau's army was now uncommonly dangerous. He maintained his position, however, till the 17th of September; but he was undecided in his movements, and was obviously at a loss how he ought to proceed. He attempted, without success, to withdraw the Archduke from the pursuit of Jourdan, by detaching a part of his troops towards Nuremberg. Many attacks were made upon him, but all of them without success; and the Imperial generals at last gave way to him wherever he turned. Finding at last that Jourdan's defeat was irretrievable, and that Bonaparte did not arrive from Italy, he resolved to retreat. He had recrossed the Lech, to prepare for this event; but now suddenly passing it again, as if determined to advance farther into Austria, he drove back General La Tour as far as Landsperg. Having thus obtained freedom for his future movements, he set out in full retreat, proceeding between the Danube at Ulm and the lake of Constance. La Tour, however, soon pressed upon his rear. He found the passes of the Black Forest occupied by large bodies of Austrians and armed peasants, while Generals Nauendorf and Petrarsch harassed his right flank with 24,000 men. Once more therefore he turned upon La Tour, at Biberach, on the 3d of October, with great impetuosity, and having defeated him, took no less than 5000 prisoners; whom he was able to carry to France. He now continued his retreat; his right wing, under General Desaix, keeping Nauendorf and Petrarsch in check, while the rest of the army cleared the passages in front till he arrived at what is called the Valley of Hell (*Val d'Enfer*), a narrow defile, running for some leagues between lofty mountains, and in some places only a few fathoms in breadth. The centre of his army, advancing in a mass, forced this passage, while the wings resisted the Imperial troops under La Tour and Nauendorf. After this desperate effort he reached Fribourg on the 13th of October, and was soon compelled by the Archduke Charles, who had now arrived from the pursuit of Jourdan, to evacuate all his positions on the Swabian side of the Rhine, with the exception of Kehl, and a temporary fortification erected at Huningen, called a bridge-

271
[illegible]ful ret[illegible]

(A) It would be improper to interrupt our military detail with the following information respecting the morals of Jourdan's army at this time; which, however, it is of importance for our readers to know. We have it from a German Count, who saw with his own eyes a considerable extent of the march and countermarch of the French through Franconia.

Almost every officer in Jourdan's army had a mistress; and such of them as by plunder could support the expence, gave balls, acted plays, and exhibited every species of gaiety when the army was not in actual motion. In all this there was nothing wonderful. The ladies, however, were not unfrequently pregnant; and as nursing would keep them from these assemblies, where their company could not be dispensed with by the soldiers of liberty, they drowned their new-born infants—*they drowned them publicly!* Our correspondent (the Count) saw two of the little victims, and he heard, from unquestionable authority, of several more. At a place within six miles of Nuremberg, a Prussian parish-minister, who was also a sort of justice, endeavoured to save one innocent, and was thrown into the river and fired at by the French, when his parishioners endeavoured to save him. He had the happiness, however, to save the child, and was allowed to keep it, the mother never enquiring after it!

French Revolution 1796.

bridge-head (*tete de pont*), though there was no bridge at that place.

The Imperial troops, in the mean time, had taken advantage of the defenceless state of the French frontier to cross the Rhine at Manheim, and to advance in various detachments to Weissemburg, Seltz, Hagenau, and almost to the gates of Strasburg, levying contributions and taking hostages wherever they came. These detachments being now recalled, the Archduke resolved to terminate the campaign by the capture of Kehl, and of the fortification at Huningen. But this proved no easy task. As the communication with the French side of the river was open at both places, the divisions of Moreau's army did duty at them by turns. A great part of the winter was spent in fruitless attempts, on the part of the Austrians, sometimes to take them by storm, and sometimes to reduce them by the forms of regular siege. Different sallies were made by the French, and immense numbers of men were lost on both sides by the sword, and by the severity of the season. It was not till the 10th of January that the French agreed to evacuate Kehl, and the fortification at Huningen was not given up till the succeeding month.

During the invasion of Germany that has been now mentioned, and the reverses that were suffered by the French armies there, Bonaparte still continued to gain victories in Italy. The success and the wonderful fortune of this man, require that we should give some account of the arts by which he was enabled, so unexpectedly, to triumph over the most experienced military commanders of the age in which he lived. In the military art three orders of battle, or forms of drawing up an army, have been chiefly adopted by those nations whose force has principally consisted of foot soldiers. The first form or mode consists of arranging the troops in a deep line; that is, with from 16 to 30 men placed close behind each other. This is the most ancient and simplest order of battle. It was carried to perfection by the Greeks, under the name of the *Phalanx*; and, when the soldiers were armed with the long spear, it was extremely formidable. It left little to the skill of the general, except the choice of the ground where he was to fight, and made all to depend upon the steadiness of the troops. It was attended with these disadvantages, however, that an army thus drawn up commanded very little territory, and that if its ranks happened to be broken by unequal ground, or an uncommon effort of the enemy at a particular quarter, its parts could not easily be re-united, and it infallibly went into confusion. In modern times, this order of battle cannot be adopted with success on account of the facility with which it is broken by artillery, and the slaughter to which it exposes the troops from every kind of fire arms. The second, or modern order of battle, consists in forming a front of an immense extent, with only two or three men in depth, and usually supporting these by another, and perhaps a third equally slender line, at a considerable distance in the rear. Troops thus drawn up derive the greatest possible benefit from their own fire arms, and suffer the least loss from those of the enemy. They provide for their own subsistence by covering an immense track of country. Their battles are not sanguinary, as they are seldom very closely engaged; and in case of a defeat, little loss is suffered, because they can scatter themselves over a wide space, as the rear protects the advanced body; and as the troops in a long line can seldom all be engaged at once, they are supported by each other in a retreat. This order of battle, however, is easily broken; and the moment the flank of an army is turned, it is under the necessity of retreating, as troops cannot speedily be brought from other quarters to face the enemy there. The last order of battle consists of dividing an army into columns of a narrow front and very great depth, and of stationing the columns at some distance from each other, with a second set of columns opposite to the intervals between the first. This arrangement is superior to the phalanx, in this respect, that it does not expose an army to disorder by inequalities of ground, by the turning of its flank, or even by the defeat of one of its parts. The celebrated Epaminondas won the battles of Leuctra and Mantinea, by forming a part of his troops, on each of these occasions, into a strong column, which, by its great depth, and the mechanical weight of its shock, broke through the Spartan phalanx. The Romans are known to have owed their military success, in a great measure, to the arrangement of their legion. It was drawn up upon the principle now mentioned; and tho' the columns were only 16 men in depth, it was confessedly superior to the phalanx. In modern times, however, this order of battle is attended with great difficulties. It must reduce an army to embarrassment with regard to provisions from the smallness of territory which is thus occupied, and it exposes the troops in an engagement to dreadful destruction from the [illegible] missile weapons which are now employed. [illegible] enterprise they must instantly carry [illegible] undone, as the fire of a few guns [illegible] or redoubt would exterminate [illegible] With all its imperfections, however, [illegible] of battle has at times been employed by [illegible] It was the favourite arrangement of [illegible]phus; and his troops were drawn up according [illegible] the battle of Lutzen, where he himself was killed, [illegible] his army was victorious. The celebrated M[illegible] Montrose also used it on more than [illegible] it was now adopted in all important [illegible] Trusting to its success, he pushed his columns into the midst of the Austrian army at Millesimo, and fairly captured one of its wings. He ventured farther to throw himself into the centre, between the Austrian and Sardinian armies, and to vanquish the one, by acting against it with his whole troops while separated from the other. Being careless about the shedding of blood, he never hesitated to expose his whole army to utter ruin in case of a failure. The success of his battles, by enabling him to lay almost all Italy under contribution, gave him the means of maintaining the most steady and severe discipline over a well paid army. Filled with high notions of military glory, which he is said to have derived from the writings of Plutarch, he laboured to inflame, with the same spirit, the minds of his soldiers by proclamations, expressed in a very different style from the formal and more modest language of modern times. "Soldiers (said he, when he first entered Lombardy), you have rushed like a torrent from the summit of the Appenines, you have driven back and dispersed all who opposed your march. Your fathers, your mothers, your wives, your sisters, your sweethearts, rejoice in your success, and boast with pride of being related to you. But

272 Reflections on the different orders of battle.

274 His pompous proclamation.

French Revolution 1796.

But remains there nothing more for you to effect? Shall posterity reproach us with having found a Capua in Lombardy? But I already see you rushing to arms; an unmanly repose fatigues you, and the days lost to glory are lost to your felicity. But let the people be tranquil: we are the friends of all nations, and more particularly of the descendants of the Brutuses, the Scipios, and the illustrious personages whom we have chosen as models. To restore the Capitol, to replace with honour the statues of the heroes who rendered it renowned, and to rouse the Roman people, become torpid by so many ages of slavery, such will be the fruit of your victories; they will form an epoch to posterity, and you will have the immortal glory of renovating the fairest portion of Europe. The French nation, free and respected by all the world, will give to Europe a glorious peace. You will then return to your homes and your fellow-citizens; who, when pointing to you, will say, *He was of the army of Italy.*"

275 Marshal Wurmser attacked.

At the commencement of the French invasion of Germany, Marshal Wurmser was sent into Italy to replace Beaulieu, who was removed from his command. On his arrival, he collected the wrecks of the Austrian army, and prepared, till he should receive reinforcements, to confine the French within as narrow limits as possible, by lines drawn from the lake of Garda to the river Adige. At the end of June, however, these lines were attacked and carried by Massena's division, which induced Wurmser to avoid farther exertion till he should receive an increase of force. In the mean time Bonaparte was a little disturbed by partial insurrections [illegible]. Soon after his arrival in Lombardy, [illegible] of Milan and of Pavia had risen in con[illegible] troops; but they were reduced to sub[illegible] bloodshed. In the beginning of July, [illegible] broke out in the Romagna. The [illegible] established their head quarters at Lugo, and [illegible] a party of French cavalry that was sent against [illegible]. It was not till Augereau had overcome them, [illegible] battle in which he [illegible] that [illegible]. The slaughter of these unhappy [illegible] great. Their town was given up to [illegible] found in arms were [illegible].

The first part of the month of July was spent by Bonaparte in commencing the siege of Mantua in regular form; and towards the close of that month he expected [illegible] capture. [illegible] however, he had ill calculated the immense military efforts which Austria, aided by the money of Britain, was capable of making. Twenty thousand troops had been sent from the Rhine, and other reinforcements were marching towards Italy from all quarters; so that Bonaparte, instead of being able to take Mantua, had speedily to defend himself against the force of a superior army to his own, that approached to raise the siege, and even threatened to drive him out of Italy. Wurmser's army descended from the Tyrol in two divisions. One half of it proceeded along the east side of the lake of Garda, and the other came by the west to cut off the retreat of the French, who were thus enclosed by the Austrians. On the 29th of July, at three o'clock in the morning, Massena was driven from the strong post of La Corona, on the east of the lake, while, at the same time, 15,000 Austrians drove the French from Salo, and afterwards took Brescia, with all the magazines and hospitals of Bonaparte's army.

French Revolution, 1796.

There was a fatal error, however, in the general plan of operations that had been formed by the Imperialists. Their army united was an overmatch for the French; but they had voluntarily divided it into two parts, placing Bonaparte between them. The error was instantly discerned, and taken advantage of by their antagonist. On the night of the 30th, he suddenly raised the siege of Mantua, and leaving a small body of troops to keep in check the Imperialists on that side, he marched rapidly westward, and on the first of August retook Brescia, with the magazines and hospitals. Having the mass of his army united, Bonaparte surpassed his antagonists in numbers wherever he encountered them. He prepared to attack the Imperialists on the 3d at Salo, Lonado, and Castiglione, but was anticipated by them. Having formed a large body of his troops into close columns, the Austrians, who were not yet aware of the nature of his mode of fighting, extended their line to surround them; a movement which enabled the columns to penetrate the Imperial army in all directions, and throw 278 He is defeated.
it into compleat disorder. The French took 4000 prisoners, and 20 pieces of cannon. The Imperial troops were here so completely defeated, that a considerable division of them having in vain attempted to retreat by Salo, which they found occupied by the French, wandered about in search of a road by which to escape; and having next day come to Lonado, they summoned it to surrender, upon the supposition that the greater part of the French army had gone eastward to encounter Wurmser. This was actually the case; but it so happened, that Bonaparte was in person at Lonado with only 1200 men. He was sufficiently perplexed by this accident; but having ordered the messenger to be brought into his presence, he threatened to destroy the whole division for having dared to insult the French army, by summoning its commander in chief to surrender. The stratagem was successful. The Imperial officers imagined that the whole army was in the place, and immediately, with their troops, laid down their arms, to the number of 4000 men.

Such is the account of this transaction, which we have from the partial pen of the panegyrist of Bonaparte, who writes the history of his campaigns in Italy; but we believe that the General has himself assigned the true reason of his success on this occasion, and others, where success could not be reasonably expected. In one of his intercepted letters, Bonaparte informs his correspondent, that the Austrian armies in Italy cost him more money than his own; and indeed it is not within the compass of supposition, that a body of veteran soldiers could have been intimidated to lay down their arms by so vain-glorious a threat as this, had not their officers been corrupted by French gold and French principles. The stratagem might have its effect upon the common soldiers, but it could not possibly impose upon their leaders, or upon the messenger who summoned Lonado to surrender.

On the 5th and 6th, Bonaparte attacked Marshal Wurmser, and drove him from Peschiera and the river Mincio. On the 7th, the Austrians were compelled to 279 Again defeated.
quit Verona, and to retire once more to the mountains of Tyrol. This contest, which had lasted more than six days, cost the Imperialists more than 20,000 men, upwards of 15,000 of whom were made prisoners. A part of the Emperor's troops had been levied in Gal-

French Revolution, 1796.

licia, the part of Poland which, in the partition of that country, had been allotted to Austria. These men seized the moment of defeat to quit a service which they disliked, and to go over to the French; a circumstance which greatly swelled the list of prisoners.

It was now necessary for the French to commence the siege of Mantua anew. The garrison in their absence had destroyed their works, and carried into the place 140 pieces of heavy cannon which they had left behind them, and procured a considerable quantity of provisions. The blockade was renewed; but the French, by the loss of their artillery, were unable to proceed to a regular siege; and by the beginning of the month of September, Marshal Wurmser, having received new reinforcements, was again enabled to attempt the relief of the place. Bonaparte having information of his intended approach, left sufficient troops to keep up the blockade, while he advanced northward with his army; and on the 4th of September drove the Austrians from the passes of St Marco and the city of Roveredo to the pass of Calliano, where they made their principal stand.

280 His masterly conduct after a third defeat.

Here a battle ensued, in which the French took no less than 6000 prisoners, and entered Trent as conquerors. Upon suffering this defeat, Marshal Wurmser adopted a measure which cannot be sufficiently approved of. Instead of retiring before the conqueror, who might have driven him to Inspruck, and arrived at a critical moment at the Danube, where Moreau, after much hesitation, had only commenced his retreat, he suddenly threw himself with his vanquished army into Bassano, upon the flank and rear of Bonaparte, and then advanced by hasty marches towards Mantua. He attempted to make a stand at Bassano on the 8th, but was defeated, and 5000 of his men were taken prisoners. He had still a considerable body of troops however. With these he pushed forward; and having fought different scattered divisions of the French at Cerea, Castellano, and Due Castello, he effected the passage of the Adige at

280 He enters Mantua.

Porto Legnano, entered Mantua with the wreck of his army, amounting to about 4000 infantry and 4500 cavalry. In this enterprise the Imperialists lost altogether 20,000 men; but the effect of it was, that it fixed Bonaparte in Italy, where he was obliged to remain watching and keeping under blockade the numerous garrison of Mantua. He hoped that its numbers would soon reduce it by famine to the necessity of a capitulation; but in this he was deceived, as the flesh of the horses, carried into it by Wurmser, afforded subsistence to the troops during a very long period.

In the mean time, the fame which their countryman Bonaparte gained by these victories, produced in the

281 Corsica revolts from Britain, and unites with France.

Corsicans a desire to change the British government for that of France. They accordingly displayed so mutinous a spirit, that the British Viceroy thought fit to evacute the island, which was no longer of any value to his government after all Italy had, in a great measure, submitted to the French. The Imperial subjects in Italy also, along with the inhabitants of Bologna, Ferrara, and Modena, who were completely corrupted by the false philosophy of the age, began now to republicanise themselves under the patronage of the French general. They sent deputies to a convention, levied troops, and abolished all orders of nobility.

The Emperor soon sent into the field a new army to attempt the relief of Mantua. In the beginning of November this army advanced under the command of Field Marshal Alvinzi, who advanced towards Vizenza on the east, seconded by General Davidovich, who descended with another division from Tyrol. Alvinzi had already crossed the Piava, when he was met by the French, and compelled to repass that river. But Davidovich, in the mean time, after several engagements, having succeeded in driving the French down the Adige towards Verona, Bonaparte was under the necessity of concentrating his forces. He now adopted his usual expedient of keeping one division of the hostile army in check, while he contended with the mass of his forces against the other. He left Vaubois with some troops to detain Davidovich, while he advanced in person against Alvinzi, who was now hastening towards Verona. He was met, on his way, by the Austrians at the village of Arcole. To seize this village, which could not be speedily turned on account of a canal, the French were under the necessity of passing a narrow bridge in the face of the fire of the Austrians. They made the attempt without success. Their officers rushed to the head of the column, and in vain attempted to rally the troops. Generals Verdier, Bon, Verne, and Lasnes, were carried off the field. Augereau advanced with a standard to the extremity of the bridge, but nobody followed him. At last Bonaparte, who in the mean time had sent Guieux with 2000 men to turn the village at two miles distance, hastened to the bridge of Arcole. Seizing a standard, he advanced at the head of the grenadiers, crying, "Follow your gene[illegible] They accordingly followed him to with[illegible] the bridge, when they were intimidated [illegible] fire of the Austrians, and their leader [illegible] to retire. Attempting to mount his [illegible] column, lest the Austrians should advance [illegible] pursuit, he was thrown into a morass, while [illegible] fire of the troops in the village; but here [illegible] ped, as the Austrians did not attempt to follow [illegible] advantage.

French Revolution, 1796.

282 Partial successes of the Austrians.

The village of Arcole was taken towards [illegible] ing by Guieux, and afterwards [illegible] On the following day (the 16th of Novem[illegible] stinate conflict ensued in its neighbourhood, in which nothing decisive was accomplished. On the 17th the Austrians, having pressed impetuously forward upon the centre of the French army, were taken by surprise upon their flank by the left wing of the French, which had been stationed for that purpose in ambuscade. Their left wing, however, maintained its ground till Bonaparte sent round a party of horse with twenty-five trumpeters to their rear, who, by the noise they made, induced the Austrians to believe themselves surrounded, and to fly on all sides in confusion.

283 They are defeated.

Here again appear evidences of treachery among the Austrian officers, though the battle of Arcole was the most severe which the French had yet fought in Italy, and extremely fatal to their officers, as well as to a multitude of their troops. During its continuance, Davidovich had succeeded in defeating Vaubois, who was opposed to him and Rivoli, and the blockade of Mantua was actually uncovered for a time. But Bonaparte now returned, after having driven Alvinzi across the Brenta, and the positions of Rivoli and La Corona were retaken, and Davidovich repulsed into Tyrol. General Wurmser, however, still held out in Mantua during

French Revolution, 1796. during the remaining part of the year; and the only fruit hitherto derived from so many victories was, that the French nation was led to look towards Bonaparte as its only invincible commander, upon whom all its hopes of conquest were to depend.

284 Negociation between Britain and France. During these military transactions, Great Britain had entered into a negociation with France. In consequence of passports obtained from the Directory, Lord Malmesbury arrived in Paris, and began the negociation with De la Croix the minister for foreign affairs. Tho' the Directory could not decently refuse to negociate, yet they were unwilling seriously to conclude a peace with Britain. On the other hand, the British ministry have since declared that, as individuals, they actually disapproved of a peace at this time, but that they thought it necessary both to negociate, and even to conclude a treaty, if proper terms could be obtained. In judging thus, they were certainly right; for the country at large, not seeing the danger of peace, was very desirous of it, whilst a desperate faction was constantly ascribing the continuance of the war to the criminal obstinacy of the British government. The negociation which was now set on foot opened the eyes of all but those who wished to sell their country to French regicides. Lord Malmesbury proposed, that the principle of mutual restitutions should be agreed upon as the basis of the treaty. After much useless altercation, and many notes had passed upon this subject, and also upon the question, how far Lord Malmesbury could negociate for the allies of Great Britain, from whom he had received no official powers, the Directory at last agreed to the general principle of mutual restitutions, but insisted that the objects of these should be specified. Accordingly, the British ambassador proposed, in two memorials, that France should relinquish the Austrian Netherlands, and offered to give up the French [illegible] settlements in return. An offer was also made to restore a great part of the Dutch foreign possessions, on condition that the Stadtholder's ancient authority should be acknowledged in that country. The Directory now required Lord Malmesbury to present the ultimatum of his conditions within twenty-four hours. On his complaining of this demand, he was informed, on the 19th of December, that the Directory would agree to no conditions contrary to the French constitution; and it was added, that his farther residence at Paris was unnecessary!

[illegible] broke off by the Directory.

286 Cape of Good Hope, with a Dutch squadron, taken by the British. During this year, Great Britain retained her usual superiority by sea. A British squadron, under Admiral Elphinston, had taken possession of the Dutch settlement at the Cape of Good Hope, on the 16th of September 1795. This settlement the Dutch wished eagerly to recover; and for this purpose they advanced money to enable the French to fit out a squadron to co-operate with them in an attack upon it. The French government took the money, but the squadron was never equipped. The Dutch themselves this year sent a squadron of seven ships of war, under Admiral Lucas, to attempt to reconquer the Cape; but being no match for the British squadron, and being likewise caught between two fires, without the possibility of escaping, the Dutch fleet, without firing a gun, was delivered up to the British admiral.

Notwithstanding the superiority of Great Britain by sea, the French, towards the close of this year, attempted an invasion of Ireland; but the plan was ill concerted, and, of course, unsuccessful. The whole conduct of it was intrusted to one man, General Hoche, and no second was prepared to occupy his place in case of any accident. The disaffected faction with whom the French meant to co-operate was not warned of their approach, and the fleet was sent towards a quarter of the country where the people were little disposed, or, at least, by no means prepared to receive them. Eighteen ships of the line, thirteen frigates, twelve sloops, and some transports, having 25,000 land forces on board, were employed in this expedition. When about to sail, it was detained for some time by a mutiny which arose in consequence of the enlistment of about 1,200 galley slaves. The fleet sailed on the 10th of December; but a ship of the line was lost in going out of Brest, and some of the rest were damaged. The frigate in which the commander in chief had embarked was separated from the fleet in a gale of wind; and the consequence was, that when the greater part of the fleet arrived at Bantry Bay, on the west coast of Ireland, nobody had instructions how to proceed. The troops and their officers wished to land, but the admiral, Bouvet, refused to comply with their request. Having remained several days upon the coast, he sailed for France, and arrived at Brest with a part of the fleet on the 31st of December. General Hoche did not reach Bantry Bay till it was too late, and therefore could not land. The fleet suffered great losses in its return. One ship of the line and two frigates foundered at sea, a frigate was taken by the British, and a ship of the line, after an engagement with two British ships, was run ashore to prevent her being captured.

287 Unsuccessful attempt by the French on Ireland.

At the commencement of the year 1797, the Archduke Charles was still occupied in the reduction of Kehl, and of the French fortifications opposite to Huningen. Moreau still commanded the army that opposed the Archduke; but General Hoche, after his return from the expedition to Ireland, was appointed to succeed Jourdan on the Lower Rhine. Bonaparte was still engaged in the blockade of Mantua, while the Austrian government was making vast efforts to recruit the army of Alvinzi after its defeat at Arcole, and to enable that General to make a last and desperate effort for the relief of Mantua. The young men of Vienna were urged to give their assistance on this important occasion, and 6000 of them marched into Italy as volunteers. Alvinzi's army amounted now to nearly 50,000 men; and he commenced his operations on the 7th of January, by skirmishing along the whole of the French line from below Porto Legnago upwards, to La Corona near the Lake Garda. He continued for some days to alarm the French at all points, and thus to conceal the plan of his future efforts. On the 10th Bonaparte was still at Bologna, on the other side of Mantua, taking precautions against the escape of Wurmser by that quarter, which, from an intercepted letter, he had learned was in contemplation. Being now informed of the approach of the Austrian army, he hastened to Mantua, and from thence to Verona, which was the centre of the line of his army that opposed Alvinzi. He arrived at Verona on the morning of the 12th; but as the Austrians continued to make their attacks upon all quarters at once, he was unable to penetrate the design of their leader. At last, on the 13th, the 1797.

288 Successes of the Austrians.

French Revolution, 1797.

the efforts of the Austrians began to assume a more formidable aspect on the lower part of his line near Porto Legnago; but on the evening of the same day he received intelligence, that the upper extremity of his line, where Joubert commanded, had been attacked by such an immense superiority of numbers, that there could be no doubt that the greatest number of the Imperial troops was concentrated there. The post of La Corona had even been forced, and Joubert compelled to withdraw to Rivoli, which he also abandoned.

198
They divide their army;

The Austrians still persisted in their unfortunate plan of dividing their army, that they might have two chances of success. Ten thousand chosen troops, among whom were the Vienna volunteers, were destined under General Provera to penetrate to Mantua by Porto Legnago, at the lower extremity of the French line; while Alvinzi in person advanced with the mass of the army against Joubert at its other extremity. On the 13th all went well; Joubert was compelled to retreat; and he was so situated, that the easy capture of his whole division on the following day appeared a very probable event.

Bonaparte, in the mean time, having learned the state of affairs, left Verona in the evening of the 13th, having first ordered the whole centre of his army under Massena to follow him to the neighbourhood of Rivoli with all possible speed. Here he spent the night with his officers in arranging the order of battle for next day, and in occupying proper positions. At day-break of the 14th the attack was begun by Joubert's division, to the no small surprise of the Imperialists, who were not aware of the arrival of Bonaparte with reinforcements. The battle, however, was long and obstinate. The superiority of numbers on the side of the Austrians enabled them to defeat all the efforts of the French to turn their divisions. They at last succeeded in driving back upon the centre the two wings of the French army in considerable disorder. Alvinzi now attacked the centre, which scarcely maintained its position; and the Austrian wings advancing on both sides, completely surrounded the French army. The victory seemed already won; and it is said that Alvinzi dispatched a courier to Vienna to announce the approaching capture of Bonaparte and his army. Bonaparte indeed considered his own situation as very alarming; and is said to have meditated his escape across the Austrian right wing. From the nature of his order of battle, his troops had rather been concentrated than scattered by the repulse they had received, and it was therefore still in his power to make a desperate effort. Having formed three strong columns, he sent them against the Austrian right wing. They succeeded in penetrating it at different points; and it fled in such confusion, that having encountered a party of French that had not arrived in time to join the body of the army, 4000 Austrians laid down their arms in a panic, and surrendered themselves prisoners of war. Night put an end to any farther contest; but Bonaparte considering this quarter of his line as no longer in danger, departed to oppose General Provera, leaving Joubert to prosecute the victory now gained. This service he performed with great success. A detachment under General Murat having marched all the night of the 14th after the battle, seized Montebaldo in the rear of the position at Corona, to which a considerable division of the Austrians had retreated, while Joubert, next morning, attacked them in front. Finding themselves surrounded, they soon fell into confusion. Six thousand men were made prisoners, many were drowned in attempting to cross the Adige, and the remainder fled to Tyrol.

French Revolution, 1797.

199
And are defeated.

During this sanguinary contest on the upper part of the Adige, General Provera had forced his passage across the lower part of that river at Angiara near Porto Legnago, and compelled the French General Guieux to retire to Ronco. Augereau collected all the troops in the neighbourhood, and marched to attack Provera; but as he hastened towards Mantua, Augereau could only come up with his rear; of which, after an engagement, he took 2000 prisoners. On the 15th, however, General Provera arrived in the vicinity of Mantua. The city, which stands in a lake, was blockaded at the two points, by which it has access to the main-land called *St George* and *La Favorite*. Alvinzi was to have formed his junction with Provera at the post of St George. Receiving no intelligence of him, General [illegible] moned the French commander [illegible] on his refusal, endeavoured to [illegible] sault. Having failed in this attempt, [illegible] tention towards the post of La Favorite, [illegible] tacked on the morning of the 16th; while [illegible] who had perceived his arrival, advanced [illegible] of the garrison against the same [illegible]. But [illegible] time Bonaparte had arrived with reinforcements [illegible] neral Wurmser was repulsed (a) [illegible] pletely surrounded by the French, [illegible] sity of surrendering himself with his [illegible] war. The result of all these battles at Rivoli and Mantua was the capture of [illegible] prisoners and 60 pieces of cannon; and thus four Imperial armies had perished in Italy in the attempt to preserve Mantua. The capture of this city, however, was now inevitable, in consequence of famine. It surrendered by capitulation on the 2d of February. Bonaparte on this occasion endeavoured to acquire the reputation of humanity. To allow the French emigrants in the garrison to escape, he consented to an article in the capitulation that General Wurmser should be allowed to select and carry out of the garrison 700 men, who were not to be examined

(a) Marshal Wurmser had before this time begun to suspect that his plans were betrayed to the enemy. When he resolved to make his last sally to co-operate with Alvinzi, he kept his plan to himself; and in the morning of that day on which the army was to march out, he gave to each of the generals commanding the divisions (which we think were seven) his orders in a sealed packet. The troops marched at the hour fixed on, in so many divisions; and they were instantly attacked at all points by the enemy. Upon this, the old General said to a British officer of high rank, who was with him in the fortress, We are betrayed, make your escape by any means that you can. This anecdote was communicated to us through a channel which leaves no doubt of its truth in our own minds; but not being authorised to give the *names* of our informers, we thought it not right to insert it in the text. Its truth or falsehood may be easily ascertained.

French Revolution, 1797.

mined nor considered as prisoners; and the General himself was allowed to depart unconditionally.

292 The Pope perseveres in hosti-

In the meanwhile, the Pope, who of all the European princes had the best reason for disliking the French cause, uncautiously persevered in hostility, in the hope that some one of the Imperial armies might succeed in driving Bonaparte from Italy. Having recovered from the panic which induced him to solicit an armistice when the French first entered Lombardy, he had avoided concluding a treaty of peace, and attempted to enter into a close alliance with the court of Vienna. He procured officers to be sent from thence to take the command of his troops, and flattered himself with the vain hope of being able to make an important diversion in favour of the Imperial troops.

As the Emperor and the French were both preparing with all possible speed to renew their bloody contest on the frontiers of Germany, it was of importance to Bonaparte to leave all Italy in peace on his rear. On the 1st of February he sent a division of his troops under General Victor, along with what was called the *Lombard Legion*, consisting of Italians, to enter the territory of the Pope; and upon the surrender of Mantua Bonaparte followed in person. The troops of his Holiness made feeble resistance. The new raised Lombard legion was made to try its valour against them on the river Senis on the 2d. After storming their entrenchments, it took their cannon and 1000 of themselves prisoners. Urbino, Ancona, and Loretto, successively fell [illegible] the French. From the chapel at Lo- [illegible] Colli had carried most of the [illegible] and silver ar- [illegible] and the image of the [illegible] a curiosity to Paris. Bonaparte [illegible] through Macerata to Tolentino. He [illegible] messenger from the Pope with offers [illegible] a treaty with his Holiness on [illegible] treaty the conditions of the armi- [illegible] and in addition to the payments [illegible] Pope promised to pay 15,000,000 [illegible] horses, with as ma- [illegible] He also engaged to pay [illegible] the French envoy Bas- [illegible] at Rome, and to apologise [illegible] for that event.

294 Bonaparte reinforced.

The French [illegible] so unsuccessful in their late irruption into Germany, through Swabia and Franconia, that they now resolved to make their principal effort from Italy under Bonaparte. For this purpose, the Directory detached great bodies of the veteran troops that had fought under Moreau as secretly as possible through Savoy into Italy. The court of Vienna, however, was aware of the approaching danger, and gave the command on the side of Italy to the Archduke Charles, who of all their military leaders had alone of late been successful against the French. He brought along with him his best troops from the Rhine, and numerous levies were endeavoured to be made in all the hereditary states for his farther support. The war was now about to be carried into new territories, on which the house of Austria had scarcely hitherto beheld a foe. It was necessary that Bonaparte should once more attempt to scale the summit of the Alps. This immense chain of mountains, which takes its rise in the vicinity of Toulon, at first stretches northward under the names of *Piedmont* and *Savoy*. It then runs towards the east, forming the countries of Switzerland, Tyrol, Carinthia, and Carniola. The three last of these, passing along the head of the Adriatic, form the frontier in this quarter of the hereditary states of Austria. Between the mountains and the sea lies the level and fertile tract of territory which belonged to Venice. It is crossed by many large streams, which are fed by the melting snows of the Alps, and whose nature is this, that they are greatest in summer, and that their waters diminish during the frosts of winter.

295 Blunder of the Court of Vienna.

The council of war at Vienna now committed an important error in the plan of defence which it adopted. Instead of making a stand in the defiles of the mountains, the Archduke was sent down into the plain to defend the passages of the rivers. War is essentially an offensive art. Whatever the general purpose of hostility may be, it is always conducted with most success when the detail of its operations is so managed as to assume the form of enterprise and of vigorous attack. This arises not from any thing in the nature of the art of war, but from the immutable constitution of the human character. The strength of men who are fixed without motion in a particular spot, is subdued by the depressing passion of fear, and by the despair of accomplishing any important object; whereas, when urged to action and to enterprise, their energy is increased by hope, and by that presumption of their own superiority which all men readily entertain. Hence we have so few instances in history of nations successfully defended by rivers or extensive fortified lines; whereas mountainous countries have usually set bounds to the progress of armies. In such situations, the defending party can always act upon the offensive. He finds his adversaries divided, by their situation, into small parties. He hopes to vanquish them in detail, and he acquires strength and courage from the prospect of success.

While Bonaparte was advancing into the territory of the Pope, the Austrian army was arranging itself along the eastern bank of the Piava. The French were on the opposite bank, and Bonaparte hastened to join them after he had concluded his treaty with the Pope. The beginning of March was spent in preparations; but at last the troops advanced, that the point of resistance might be discovered. Having crossed the Piava on the 12th of March, the Austrians retired, skirmishing for some days till they had crossed the Tagliamento, where they made a stand with their whole force. Early on the 17th the French army arrived at Valvasone, on the opposite bank; and after some hesitation, resolved to force the passage of the river. To have accomplished this object very speedily would have been difficult, had not a recent frost diminished the stream, by which means the French were enabled to cross it in the face of the enemy in columns at various points. The army of Bonaparte was now in three divisions. Joubert, with the left wing, advanced along the course of the Adige into Tyrol, and was ordered to cross over from thence, and to descend along the valley of the river Drave, which is beyond the highest chain of what the Romans called the *Noric Alps*. Massena, with the centre, after crossing the Tagliamento, advanced into the defiles of these mountains; while the right division, which was attended by Bonaparte in person, proceeded along the coast of the Adriatic.

296 Progress of the French army.

French Revolution, 1797.

After forcing the paffage of the Tagliamento on the 17th, the French had eafily defeated the Auftrians on the oppofite bank, and compelled them everywhere to retreat. The other rivers were eafily paffed; and on the 19th, the town of Gradifca, on the river Lifonzo, furrendered to the right wing of the army, and its garrifon, amounting to 3000 men, were made prifoners of war. On the 21ft Goritz was entered by the fame divifion, who found there the principal Auftrian magazines and hofpitals. Triefte was entered on the 23d; and the French fent off in waggons, from the quickfilver mines of Ydria, materials worth 2,000,000 of livres. In the mean time, the Auftrians, in their hafty retreat, entangled themfelves and their baggage among the mountains. On the 24th, a large body of them was hemmed in between Maffena, who had reached Tarvis, and a part of the French right wing under Guieux. Reinforcements, however, having found means to reach them from the Archduke's head quarters at

297 The Auftrians defeated.

Clagenfurt, they hazarded an engagement on the following day, but were defeated, with the lofs of 5000 taken prifoners, and 400 waggons loaded with baggage. The French left wing under Joubert, Baraguay D'Hilliers, and Delmas, was equally fuccefsful. On the banks of the Lavis, after an obftinate engagement, 4000 Auftrians were taken; and thereafter at Clauzen they were again defeated, with the lofs of 1500 taken prifoners. Having entered Brixen, this divifion turned eaftward, and defcended the valley of the Drave towards Clagenfurt, the capital of Carinthia, where it was met by General Maffena; the Archduke, after a flight conteft, having evacuated the place, and advanced farther towards the capital of the empire, which was now

298 Wonderful fuccefs of Bonaparte.

ferioufly menaced, and in which great confternation prevailed. In 15 days Bonaparte had taken 20,000 prifoners, and croffed the Alps; and though the country ftill prefented fome difficulties, there was no fortified place capable of refifting his progrefs towards Vienna. He did not, however, confider his own fituation as deftitute of hazard, and feized the prefent moment of unbounded fuccefs to make propofals of peace. On the 31ft of March he fent a letter to the Archduke, in which he deprecated the ufelefs prolongation of the war, and intreated him to interpofe his good offices to put a ftop to its farther ravages. But this prince, who feems to have doubted his own influence at the court of Vienna, returned a cold anfwer, ftating, that it belonged not to him to inveftigate the principles on which the war was carried on, and that he had no powers to negociate.

299 Partial fucceffes of the Auftrians.

The Auftrian chiefs made a laft effort, by raifing the peafants of the Tyrol in a mafs to embarrafs the rear of the French. They accordingly gained fome fucceffes under General Laudohn, and drove out the French troops that had been left at Botzen and Brixen. The inhabitants of the Venetian ftates alfo rofe againft the troops that remained in their country; and being joined by ten regiments of Sclavonians, which had been in the pay of the government of Venice, they put the French to death wherever they were found, without excepting the fick in the hofpitals, of whom 500 were maffacred at Verona. A party of Imperialifts alfo drove the French garrifon out of Triefte, and thus attempted to furround the invading army. Bonaparte, however, knew that the court of Vienna muft be at leaft as much embarraffed as himfelf. His army amounted to 95,000 men. It had hitherto proved irrefiftible; and the Auftrians knew, that to furround was not to conquer it. He therefore perfifted in advancing. On the 2d of April he fucceeded in forcing the ftrong defiles between Freifach and Newmark, after a bloody battle, in which he took 600 prifoners. On the 4th, his advanced guard reached Hunfmark, where the Auftrians were again defeated; and his army occupied Kintenfeld, Murau, and Judenbourg. Thefe advantages compelled the Auftrian cabinet to treat for peace, as there was no longer any point at which the Archduke's army could hope to make a ftand till it came to the mountains in the vicinity of Vienna. Measures were taken for removing the public treafure and effects into Hungary, while Generals Bellegarde and Morveld were fent to requeft from Bonaparte a fufpenfion of hoftilities. On being fuffered to take poffeffion of Gratz and Leoben, within little more than 50 miles of Vienna, he confented, on the 7th of April, to an armiftice, which was only to endure till the night of the 13th, but was afterwards renewed for a longer period. It was followed on the 19th by a preliminary treaty, figned at Leoben; by which it was agreed that the Auftrian Netherlands fhould belong to France, and that the new republic in Lombardy fhould continue under the name of the *Cifalpine Republic*, and fhould include the Milanefe, the duchy of Mantua, and the territories of Modena, Ferrara, and Bologna. There is reafon to fufpect that fomething hoftile to [illegible] nice was here [illegible] withdraw without delay into [illegible] fiftence for his army during [illegible] folved, that all farther [illegible] fettled by a definitive treaty of peace. [illegible] he accufed the Venetian government [illegible] the infurrection which had taken place [illegible] in his abfence; and having feized [illegible] territory, he diffolved [illegible] now feeble, [illegible]

300 The Auftrian cabinet treats for peace.

While Bonaparte [illegible] French armies on the Rhine [illegible] the Auftrians, to prevent [illegible] from being fent againft him from that [illegible] The Auftrians offered an armiftice; but as the French demanded the fortrefs of Ehrenbreitftein as the price of it, both parties prepared for action. The left wing of the army of General Hoche advanced rapidly from Duffeldorf, while the centre and right wing croffed the Rhine near Coblentz. The Auftrians under General Wernecht retreated to the Lahn, where they waited the arrival of the French. Here a violent conteft enfued on the 18th of April, in which 4000 Auftrians were taken prifoners. The French took poffeffion of Wetzlaer, and drove their antagonifts to the gates of Francfort. In the mean time, General Moreau, on the Upper Rhine, forced the paffage of the river near Strafburg, and attacked the village of Dierfheim, of which he at laft retained poffeffion, after having been more than once driven out, and the village nearly deftroyed. The following day, however, the Auftrians renewed the attack, and forced the French for fome time to give way; but powerful reinforcements having croffed the river,

302 Succeffes of the French on the Rhine.

French Revolution, 1797.

river, the French were at last enabled to renew the battle with such vigour, that they took Fort Kehl, together with 5000 prisoners. The Imperialists in this quarter were now pursued towards the Danube; when all military operations were suddenly arrested by messengers sent through Germany by the Archduke Charles and Bonaparte, announcing that peace was concluded. These messengers found the army of Hoche violently attacking Francfort on the Maine, which General Wernecht was endeavouring to defend. The news was diffused in an instant through both armies; and the contending troops, throwing aside their weapons, congratulated each other upon the event.

303 Peace concluded.

304 Power of France at this period.

France now held a very elevated rank, and a formidable character, among the nations of Europe. Spain, Italy, and Holland, were held in dependence; while her victorious armies had compelled the last continental member of the coalition to accept of peace from an army that approached his capital. Had the Austrian officers been faithful, and the court of Vienna less selfish, subsequent events have indeed shewn that the affairs of the Emperor were not yet desperate, and that Bonaparte was not that invincible hero which his rapid successes gave some reason to suppose him. After the perusal of his letters from Egypt, his victories lose much of their brilliancy [illegible] all the actions of his life, [illegible] as the retreat of Moreau [illegible] when pressed on the rear by a victorious [illegible] surrounded on all hands [illegible] populace. But Bonaparte had been [illegible] knew not whom to trust: [illegible] that his plans were continually [illegible] council at home; and the [illegible] to make a peace. Of all [illegible] French revolution, Britain alone re[illegible]. From her command of the ocean [illegible] to retain the feeble state of Por[illegible] cause; but on land, such was the [illegible] that, with this exception, [illegible] by tolerance, the British [illegible] by her influence, from [illegible] from the Elbe to the A[illegible] British government was once more in[illegible] to try the effect of a new negociation. All these external advantages, however, were speedily lost by the French nation; and it seemed the unhappy destiny of this people to be constantly deprived of the fruits of all their sufferings, and their courage, by the turbulence of their domestic factions, and the profligacy and unprincipled conduct of their rulers.

306 Contest between the Directory and Councils.

A serious contest between the executive power and the legislature was now approaching. We already remarked, that the Directory was originally selected by those men who had been the associates of Robespierre; and though deserted of late by some of the more violent spirits, who were termed *Anarchists*, it was still considered as the head of the Mountain party. By the victory obtained over the sections of Paris on the 5th of October, all opposition had been set at defiance for a time; but the nation at large had never been reconciled to these men. The period now arrived when a third of the legislative body was to be changed. On the 19th of May, Letourneur went out of the directory by lot. On the 20th, the new third took their seats in the Councils, a third of their predecessors having evacuated their seats by lot; and on the following day, Barthelemi, the ambassador to Switzerland, was chosen to succeed Letourneur in the Directory. The election of the members of the new third had almost entirely fallen upon men who were understood to be hostile to the Directory. Many Generals out of employment were chosen; such as Pichegru, Jourdan, and Willot, and many representatives of the families of the ancient nobility who had not emigrated (among whom was the prince of Conti) were now elected into the legislature. The moderate or opposition party in the two Councils now possessed a complete majority. Carnot and Barthelemi were understood to be favourable to them in the Directory; the former having made his peace with them, and the latter being established by themselves. The effect of this change in the state of the Councils speedily appeared in their adopting every measure that could embarrass the Directory, or cast odium upon the Mountain party, and alter the state of things which it had established.

On the 14th of June, Gilbert Desmolieres brought forward a report from a committee upon the state of the finances; in which he exhibited and reprobated in the strongest terms the prodigality of the Directory, and the profusion and rapacity of its agents. On the 18th the same committee proposed a new plan of finance, the object of which was to deprive the Directory of any share in the administration of the public money. In the mean time, on the 17th of the same month, Camille Jourdan had presented a long report on the subject of religion; in which he endeavoured to demonstrate the impropriety of prohibiting the public display of its ceremonies, and the injustice of the persecution which its ministers had undergone for refusing to take oaths prescribed by the legislature. This report was afterwards, on the 15th of July, followed up in the Council of Five Hundred, by a decree, repealing all the laws against refractory priests, or which assimilated them to emigrants. On the following day, another decree, requiring from them a declaration of fidelity to the constitution, could only be carried by a majority of 210 against 204. A proposal was now brought forward in the Council of Five Hundred by Emery, a new member, to repeal the laws which confiscated the property of emigrants, and to allow their relations to succeed to them as if they had died at the period of their emigration. Those who had fled into foreign countries from Toulon and other places, during the reign of terror, were also encouraged to return, and allowed to expect that their names would be erazed from the list of emigrants. The conduct of the Directory towards foreign powers was attacked on different occasions; and Dumoullard proposed the appointment of a committee to enquire into the external relations of the republic. This was a delicate subject; as it involved the character of the armies and their leaders, and as it might subvert the interests of the Directory with some of their friends of the Mountain party. The Venetian republic, though a neutral state, had been overturned by Bonaparte on account of a popular insurrection, for which the government apologised. Little account had been given of the immense sums of money that had been levied in Italy. The armies in the preceding year had entered Germany in the character of

307 Mild measures of the Councils.

plunderers;

French Revolution, 1797.

plunderers; which had disgusted all those in that country who had once been friendly to their cause, and longed for their arrival. The Directory, at the same time, instead of encouraging the progress of revolution, which the Jacobins eagerly desired, had suddenly made peace with the German princes, upon receiving pecuniary contributions, which were left to be exacted according to the ancient laws of the different states (which exempt the nobles and the clergy), and thus fell heaviest upon those very persons who had cherished the new republican principles.

The discussion of these subjects brought the majority of the Directory and of the Councils into a state of complete hostility. Both parties resolved to violate the constitution, under the pretence of preserving it. The one wished to change the Directory before the time prescribed by law, and the other to deprive of their seats a great number of the new legislators elected by the people. Barras was the most obnoxious of the directors; and an attempt was made to deprive him of his office, upon the footing that he was less than 40 years of age. But his colleagues asserted that he was born in the year 1755; and as no proof to the contrary could be brought, this abortive attempt served only still farther to irritate the contending parties, and they began to prepare for more effectual measures. Had not force been speedily used on the side of the Directory, the Councils must naturally have prevailed.

308 Their popularity

The majority of the people confided in them. The national purse was in their hands; and they hoped to subdue the Directory, as the constituent assembly had done the king, by avoiding to vote the necessary supplies. They could enact what laws they pleased. They had not indeed the command of the armies; but to remedy their weakness in this respect, General Pichegru, on the 20th of July, presented a plan for reorganising the national guard, and placing it more at the disposal of the Councils by depriving the Directory of the nomination of the officers.

In the mean time the Directory was by no means destitute of adherents. The resolutions of the Councils in favour of the priests, and the relations of emigrants, looked so like a desertion of former maxims, that many persons expected an immediate counter-revolution. The royalists gained courage, and a multitude of journals or newspapers, favourable to their cause, began to be published. Emigrants obtained passports, and hastened to Paris in the hope of being struck off the list, upon alleging that they fled to avoid proscription during the power of the Jacobins. The effect of all this was, that the purchasers of national property, and those who had become rich by the revolution, were alarmed. The whole Mountain party, and all those who had been active in opposition to royalty, rallied round the Directory. The armies, whose chiefs found themselves involved in some of the accusations brought against that body, sent addresses, in which they declared their resolution to support its power. The Councils declared these addresses, which the Directory had received from armed bodies, unconstitutional, and procured counter addresses from different departments. At last the partizans of the two contending powers began to distinguish themselves in Paris by their dress, and every thing presaged an approaching appeal to force. On the 20th of July the Councils received intelligence that a division of the army of General Hoche had advanced within a few leagues of Paris; whereas, by the constitution, the Directory incurred the penalty of ten years imprisonment if it authorised troops to approach nearer to the residence of the legislative body than twelve leagues, without its own consent. An explanation of this event was immediately demanded. The Directory denied that they had ordered the march, and ascribed it to a mistake of the officer by whom it was conducted. Their explanation was treated with contempt, and much angry debate took place in the Councils concerning it; the Directory all the while conducting themselves with much seeming moderation, and even submissiveness. In the mean time their antagonists acted a very undecided part.

309 The Directory victorious.

They long hoped to gain Lareveillere Lepaux to their side; in which case they would have had a majority in the Directory. This vain expectation rendered their conduct indecisive. At length the majority of the Directory procured an address of adherence from the suburb St Antoine, which in all the tempestuous days of the revolution had been the rallying point of the Mountain party. Encouraged by this address they proceeded to immediate action. General Augereau had been sent from Italy under pretence of presenting some Austrian standards to the Directory, and he was employed as their tool upon this occasion. They commanded the garrison of Paris, and they had managed to bring over to their party the soldiers composing the guard of the two councils. Before day-break on the morning of the 4th, Augereau surrounded the Thuilleries with a division of the troops. The guard of the Councils refused to resist, and [illegible] was taken prisoner. Having [illegible] Pichegru and other twelve of the [illegible] party sitting in consultation, and [illegible] prisoners to the Temple. Some other [illegible] bers of the Councils were also put [illegible] director Carnot had made his escape [illegible] the [illegible] evening, but Barthelemi remained [illegible]

All this was accomplished [illegible] instant. Many members of the [illegible] came to the hall at the usual [illegible] find that seals were put upon the doors [illegible] could not obtain admittance. They were [illegible], however, to go to the Surgeons Hall and the theatre of the Odeon, where they were told the Directory had appointed the Councils to assemble. At these places, about forty of the Council of Ancients, and double that number of the other Council, assembled about noon, and sent to demand from the Directory an account of the proceedings of the morning. They received an answer, declaring, that what had been done was necessary to the salvation of the Republic, and congratulating the Councils *on their escape* from the machinations of royalists.

310 Pretended conspiracy

Being still at a loss how to act, the Council of Five Hundred appointed a committee of four members (of whom Sieyes was one) to report upon the measures to be adopted. On the following day Boullay de la Meurth presented a report from this committee, in which he announced, that a vast royalist conspiracy, whose centre was in the bosom of the Councils, had been formed to overturn the constitution, but that it had been baffled by the wisdom and activity of the Directory. The report concluded, by proposing the immediate transportation of the conspirators without a trial.

French Revolution, 1797.

trial. Accordingly, these degraded representative bodies proceeded, after some debate, on hearing the names of the accused persons read over, to vote the transportation to Guiana in South America, of fifty-three of their own members, and twelve other persons, among whom were the directors Carnot and Barthelemi. They annulled the elections in forty-nine departments, repealed the laws lately enacted in favour of the disaffected clergy and the relations of emigrants; and even so far abolished the liberty of the press, as to put all periodical publications under the inspection of the police for one year. New taxes were voted without hesitation, Francis de Neufchateau and Merlin were elected to fill the vacancies in the Directory, and affairs were endeavoured to be conducted in their ordinary train.

All this while the city of Paris remained tranquil. That turbulent capital, which had made so many sanguinary efforts in favour of what it accounted the cause of freedom, had been so completely subdued since its unfortunate struggle on the 5th of October, that it now permitted the national representation to be violated, and the most obvious rules of practical liberty to be infringed, without an effort in their defence. The Directory, in the mean time, attempted to justify their conduct to the nation at large, by publishing various documents intended to prove the existence of a royalist conspiracy. The most remarkable of these was a paper, said to be written by M. d'Antraigues, and found by Bonaparte at Venice; in which a detail [illegible] of a correspondence between General Piche- [illegible] of Condé in the year 1795. The [illegible] also, at the same time, said to [illegible] Moreau among papers taken by [illegible] passage of the Rhine. It stated, that [illegible] offered to the Prince of Condé to cross [illegible] with his army, and having joined the Au- [illegible] General Wurmser, and the emigrants un- [illegible] Condé, to return with the united ar- [illegible] Paris, where they were to re-establish [illegible] to have refused to accept of the [illegible] of the participation of the Austrians in [illegible] of the transaction. He therefore insisted that it should be conducted without their aid; but Pichegru thought the attempt too hazardous in this form, and, being soon after removed from his command, the project failed. At the time of its publication, the genuineness of this correspondence, and also of the paper found by Bonaparte, was denied; and nothing has appeared since to induce an unprejudiced man to think otherwise at present. Moreau, who was certainly involved in this conspiracy, if real, has been intrusted since that period with the command of the armies of the republic; and though defeated by Marshal Suwarrow, he is so far from being now considered as a royalist, that the revolutionary government seems inclined to intrust to his military skill and fidelity its last efforts for the continuance of its existence.

From the violation of the representative government that has been now stated, it became obvious to surrounding nations, that France had passed under the dominion of a small faction at variance with the majority of the people. The Directory was all powerful. Its members, however, seem very soon to have become giddy by the elevated nature of their situation, and to have adopted a notion that there was no project of ambition or rapacity in which they might not venture to engage. During their contest with the Councils, they had protracted the negociations with Lord Malmesbury at Lisle, and had suffered those to relax which had been entered into between Bonaparte and the Imperial ambassadors at Campo Formio near Udine. Great Britain had offered to consent to peace, on condition of being allowed to retain the Dutch settlement of the Cape of Good Hope, and the Spanish island of Trinidad, which had been taken in the month of February this year. The Directory now recalled their former negociators Letourneur and Maret, and sent two others, Treilhard and Bonnier, in their stead; who immediately demanded whether Lord Malmesbury had full power to restore all the settlements taken from France and her allies during the war? Upon his Lordship's declining to answer such a question, because it implied an enquiry, not into his powers, which were in the usual form, but into his instructions, which would preclude all negociation, he was required to return home to procure more ample powers. The negociations with the Emperor, however, were now speedily brought to a conclusion. On the 17th of October, a definitive treaty was signed at Campo Formio. By it the Emperor gave up the Netherlands to France, the Milanese to the Cisalpine republic, and his territories in the Brisgaw to the Duke of Modena, as an indemnification for the loss of his duchy in Italy. The Emperor also consented that the French should possess the Venetian islands in the Levant of Corfu, Zante, Cephalonia, Santa Maura, Cerigo, and others. On the other hand, the French Republic consented that the Emperor should possess in full sovereignty the city of Venice, and its whole other territory, from the extremity of Dalmatia round the Adriatic as far as the Adige and the lake Garda. The Cisalpine Republic was to possess the remaining territory of Venice in this quarter, along with the city and duchy of Mantua, and the ecclesiastical states of Ferrara and Bologna.

Upon whatever principles the war might have hitherto been conducted, the terms of this treaty sufficiently demonstrated to all Europe, that its lesser states had no better reason to expect security from the house of Austria than from that of the new republic. This truth would have been still more evident, had the articles of a convention, which was signed by these parties at the same period at Campo Formio, been published to the world. Fearing, however, to alarm too much the Germanic body, these articles were kept secret, and the parties agreed to prevail with the German princes, at a congress to be opened at Rastadt, to consent, in consequence of an apparently fair negociation, to what France and Austria had determined should take place. By the secret convention or treaty now alluded to, it was stipulated, that the Rhine, including the fortress of Mentz, should be the boundary of the French Republic; that the princes, whose territories were alienated by this agreement, should be indemnified by the secularization of church lands in Germany; that the Stadtholder of Holland should be indemnified for the loss of his estates in that country, by receiving German territory; that the Emperor should receive the Archbishopric of Saltzburg, and the part of the circle of Bavaria situated between that archbishopric, the rivers Inn and Salzt, and the Tyrol; that the Imperial troops should immediately withdraw to the confines of the hereditary states be-

312 The Directory all powerful.

French Revolution, 1797.

French Revolution, 1797.

yond Ulm; and if the Germanic body should refuse peace on the above terms, it was stipulated, that the Emperor should supply to it no more troops than his contingent as a co-estate amounted to, and that even these should not be employed in any fortified place.

These treaties were immediately begun to be put in execution. The Austrians left the Rhine, which enabled the French to surround the fortresses of Mentz and Ehrenbreitstein. Of the former, they speedily obtained possession; but the latter cost them a very tedious blockade, before the garrison, consisting of troops of the Palatinate, would agree to surrender. The Imperial troops, at the same time, entered Venice; the French having evacuated that city after carrying off or destroying its whole navy. The Cisalpine Republic was established, and Bonaparte left Italy; leaving, however, an army of 25,000 men to garrison Mantua, Brescia, Milan, and other places, and to retain this new republic in dependence upon France. Genoa was, at the same time, brought under a similar dependence by means of popular commotions, instigated by the French, and a revolution in its government which took place at this period. And thus the French Directory, without the excuse of hostility, as in the cases of Holland and Spain, began a system of interference in the affairs of weaker neighbouring states, which was speedily carried to an height that once more alarmed all Europe. These men even attempted, at this time, to compel the states of North America to purchase with money their forbearance from war. This was done through a circuitous channel, and in the form of an intrigue, by private persons, who were instructed to inform the American ministers at Paris, that a large loan on the part of America would be the best means of securing peace; and it was hinted, that it would be rendered more acceptable if accompanied with a private present of L. 50,000 sterling to the members of the Directory. This last proposal was indeed denied by the French minister Tallyrand, who had given his countenance to this crooked negociation: but the general impression produced by the transaction could not be removed; and its effect was to injure very deeply the character of the French government in the opinion of those distant nations that were otherwise disposed to regard it in the most favourable light. Nor was its respectability increased by a law which the two Councils, at the desire of the Directory, thought fit to enact, declaring the ships of all neutral states bound for Britain, or returning from thence, liable to capture. This law was not less impolitic than unjust. It placed the whole carrying trade of the western world in the hands of the British, and thus enriched the very people whom it was intended to injure.

313 Violent measures of the Directory.

For at this period Britain had acquired over the ocean a degree of uncontrouled dominion that was altogether unexampled in former times. During the whole year the French fleet lay blockaded in its own ports, and no enterprise was attempted by sea, excepting in one solitary but singular instance. We have already mentioned that a number of galley slaves were sent as soldiers with Hoche in his attempt upon Ireland. On the failure of that expedition, the Directory were at a loss how to dispose of these men. They could not now with propriety be sent back to punishment, the troops would not serve along with them in the army; and as the new laws of France allow no remission of crimes, they could not receive a pardon, nor was it safe to let loose upon the country 1400 criminals. In this dilemma, the Directory resolved to throw them into England. Accordingly, they were sent in two frigates and some small vessels to the coast of Wales, and there landed with muskets and ammunition, but without artillery. In the evening of the very day on which they landed, the 23d of February, they surrendered themselves prisoners of war to a party of militia, yeomanry, cavalry, colliers and others, under the command of Lord Cawdor. The Directory boasted that, by this enterprise, they had demonstrated the possibility of landing troops on the British coast in spite of the vigilance of the navy; but this assertion was ill supported by the fate of the two frigates accompanying the expedition; both were captured in attempting to return to Brest.

314 Invasion of Wales.

Though the French navy remained in port, and consequently safe during the rest of the year, their allies, the Spaniards and Dutch, suffered severely. On the 14th of February, a British fleet of 15 sail of the line, under the command of Sir John Jervis, engaged the Spanish fleet, amounting to 27 sail of the line, off Cape St Vincent. In this action, the Spanish force, if it be estimated by the number of men, the number of guns, and the weight of metal, was more than double that of the British; but by the skilful manœuvres of its heroic commander, the British fleet twice crossed through the line of the Spaniards, and succeeded in cutting off a part of their fleet from the rest. Four ships of the line were taken, and the Spanish admiral's own ship [illegible] difficulty. The fleet had been [illegible] join the French fleet there; but [illegible] action, it returned to Cadiz, where it was [illegible] the British.

315 Brilliant victory of Sir John Jervis over the Spanish fleet,

For his gallant conduct in this engagement, [illegible] when every circumstance is taken into consideration, is perhaps unparalleled in the annals of naval [illegible] John Jervis was immediately created [illegible] and received the thanks of both [illegible] Parliament.

The Dutch were still more unfortunate. The Texel, within which their fleet lay, was blockaded during the whole summer by Admiral Duncan. The French intended, by means of the Dutch fleet, to make another attempt upon Ireland. Troops were accordingly embarked, under the command of General Daendels; but a resolution having at last been adopted of hazarding an engagement with the British, the Dutch admiral De Winter, in opposition to his own remonstrances, was ordered to put to sea. The British admiral had by this time left his station near the Texel, and gone to Yarmouth to refit. On receiving intelligence, however, that the Dutch had sailed, he instantly proceeded in quest of them. On the 11th of October the British fleet, amounting to 16 sail of the line, and 3 frigates, came in sight of the Dutch fleet, which in force was nearly equal, within about nine miles of Camperdown in Holland. Admiral Duncan immediately run his fleet through the Dutch line, and, though on a lee shore, began the engagement between them and their own coast. A most bloody and obstinate conflict ensued, which lasted nearly three hours. By that time, it is said that almost the whole Dutch fleet had struck. The ships could not all be approached and seized, however.

316 And of Admiral Duncan over the Dutch.

French Revolution, 1798. ever, on account of the shallowness of the water upon the coast, to which the fleets were now very near. Eight ships of the line, with two of 56 guns, and one of 44, were taken, besides a frigate, which was afterwards lost near the British coast, and one of the ships of 56 guns foundered at sea. Admiral de Winter was taken with his ship, and also the Vice-admiral Rentjies.

Similar honours were conferred upon Admiral Duncan as upon Sir John Jervis, and both admirals had each a pension of L. 2000 *per annum* conferred upon him for life, with the full approbation, we may venture to say, of every well-affected man in the kingdom.

1798. 317 Decline of public spirit in France. The internal history of France now ceased to be very interesting. Political freedom could not be said to exist after so many of the representatives chosen by the people had been driven from the legislature, and the departments reduced to the necessity of electing men more acceptable to their present rulers. Public spirit therefore rapidly declined. The high notions of the freedom and felicity it was about to enjoy, which had once been so eagerly cherished by a great part of the nation, now gave way to a growing indifference about political questions, and the future destiny of the republic; for the people at large found themselves little interested in a government which existed independent of their will, which consisted of a narrow circle of persons, and whose conduct was surely not less crooked, intriguing, and unprincipled, than that of the ancient royalty, and its attending court, from which they had escaped; whilst its ferocious cruelty, and total disregard even of the [illegible] were infinitely greater. But though [illegible] all-powerful, yet its power was limited [illegible] state of things, which denied it [illegible] of an abundant revenue. It had not yet [illegible] possible to re-establish a system of produc[illegible]. The legislative councils, indeed, who [illegible] with every wish of the Directory, voted [illegible], but these were scantily paid; part[illegible] total loss of the national com[illegible] the people were not disposed to [illegible] in this way for the support of go[illegible]. By the constitution, they still possessed the [illegible] of the judges and other magistrates; the country was filled with veteran soldiers, who at different times had returned from the armies after the lapse of

318 Measure of the Directory. the usual period of service. The Directory, kept in awe by these circumstances, turned its attention abroad, and found means to establish an extensive patronage, by dividing among its adherents the plunder of neighbouring states, in whose welfare the people of France were little interested. The Girondist party had formerly proposed to propagate their principles by establishing a number of petty republics in the vicinity of France. The Directory now adopted the same project; that, under the pretence of diffusing liberty, they might obtain new sources of revenue and of power, by the dominion which they meant to exercise over these new governments. Holland and the Cisalpine republic were already placed in dependence upon them; and Rome and Switzerland readily afforded them opportunities for extending their plan.

319 Embassy to Rome. After the treaty with the Emperor had been concluded at Campo Formio, Joseph Bonaparte, brother of the General, had entered Rome as ambassador from the French Republic. The Pope, now deprived of all hope of foreign aid, and accustomed to humiliations, had submitted to every demand made by him for reducing the number of his troops, and setting at liberty persons imprisoned on account of political opinions. But an event soon occurred to afford the Directory a pretence for accomplishing the ruin of this decayed government. On the 26th of December 1797, three persons had waited upon the French ambassador, and solicited the protection of his government to a revolution which a party at Rome meant to accomplish. He rejected their proposals, and dissuaded them from the attempt; but did not, as was certainly his duty, communicate these proposals to the papal government, to which he was sent on a friendly embassy. On the following day, however, a tumult took place, in which the French cockade was worn by about 100 insurgents. They were speedily dispersed, but two of the Pope's dragoons were killed. The ambassador, who probably knew the disposition of the Directory towards the Pope, seems to have resolved that his own personal conduct should be blameless on the occasion. He therefore went on the 28th of December to the secretary of state, and presented a list of the persons under his protection who were entitled to wear the French cockade, consenting that all others adopting it should be punished. He also agreed to surrender six of the insurgents who had taken refuge in his palace. Towards the evening of this day, however, the popular tumult became more serious, particularly in the courts and neighbourhood of the French minister's palace. The Pope appears to have been personally unacquainted with the state of affairs; but the governor of the city sent parties of cavalry and infantry to disperse the insurgents. About twenty persons, having a Frenchman at their head, had, in the mean time, rushed into the palace, and demanded aid towards accomplishing a revolution. A number of French officers, and others who were with the ambassador, proposed to drive the whole insurgents by force from the jurisdiction of the palace. This was certainly a salutary advice, and such as could not have been rejected by the ambassador, had not his designs been hostile to the established government. Rejected, however, it was; for, pretending to believe that his authority would be sufficient to accomplish the object in a peaceable manner, he went out into the court to address the multitude. He was prevented from doing so by a discharge of musquetry from the military, who were firing within the jurisdiction of the palace. He interposed with his friends between the military and the insurgents; and while a part of the French officers in his train drove back the insurgents with their sabres, the ambassador advanced towards the soldiers, and demanded why they presumed to violate his jurisdiction? as if the jurisdiction of a foreign ambassador were a legal asylum for men in open rebellion against the government of the state. It is not, therefore, surprising, that no attention was paid to this arrogant and absurd demand; and the nature of the ground being such, that the troops could fire over his head upon the multitude in the rear, they made a second discharge, which killed several of the insurgents. Upon this the ambassador advanced close upon the soldiers, to prevail with them to depart; but they remained in a menacing attitude, and prepared for another discharge. Eager to prevent this, the French General Duphot, who was with the ambas-

ambaſſador, and was next day to have married his ſiſter, ruſhed into the ranks of the military, intreating them to deſiſt. Here a petty officer of the Pope's troops

321 A French general killed.

diſcharged his muſket into the body of Duphot. Upon this, the ambaſſador and his other friends found it neceſſary to make their eſcape through a bye-way into the palace. The Spaniſh miniſter hearing of this event, ſent to the ſecretary of ſtate to proteſt againſt this violation of the privileges of ambaſſadors. But the government, equally alarmed and perplexed by the fear of a revolution, and of French vengeance, remained during many hours totally inactive. All this while the palace of the French ambaſſador remained cloſely beſet by the military, who occupied the whole of its juriſdiction, and all its courts and paſſages. He at laſt ſent to demand paſſports, to enable him to leave the territories of the Pope. They were granted; but with many proteſtations of the innocence of the government, and its regret on account of this unfortunate occurrence.

Joſeph Bonaparte retired to Florence, and from thence to Paris. The Pope ſolicited the protection of the courts of Vienna, Naples, Tuſcany, and Spain; but they all ſtood aloof from his misfortunes: and this government, which had once poſſeſſed the moſt uncontrouled dominion over the minds of men, now fell without a ſtruggle. General Berthier, at the head of a body of French and Ciſalpine troops, encountered no

322 The papal government overturned.

oppoſition in his march to Rome, where he overturned the government of the Pope, and proclaimed the ſovereignty of the Roman people, with circumſtances of wanton inſult; which convey a ſtriking example of French humanity and French delicacy.

"That the head of the church might be made to feel with more poignancy his humiliating ſituation, the day choſen for planting the tree of liberty on the Capitol was the anniverſary of his election to the ſovereignty. Whilſt he was, according to cuſtom, in the Siſtine chapel celebrating his acceſſion to the papal chair, and receiving the congratulations of the cardinals, Citizen Haller, the commiſſary general, and Cervoni, who then commanded the French troops within the city, gratified themſelves in a peculiar triumph over this unfortunate potentate. During that ceremony they both entered the chapel, and Haller announced to the ſovereign Pontiff on his throne, that his reign was at an end.

"The poor old man ſeemed ſhocked at the abruptneſs of this unexpected notice, but ſoon recovered himſelf with becoming fortitude; and when General Cervoni, adding ridicule to oppreſſion, preſented him the national cockade, he rejected it with a dignity that ſhewed he was ſtill ſuperior to his misfortunes. At the ſame time that his Holineſs received this notice of the diſſolution of his power, his Swiſs guards were diſmiſſed, and republican ſoldiers put in their place." — 323 Cruel treatment of the Pope.

He was himſelf removed to the territory of Tuſcany, where he reſided in much obſcurity, till his enemies, driven from Rome in their turn, thought fit to carry him ſtill farther from his capital, to end his days beyond the Alps.

In the mean time, the Roman ſtates were converted into a republic after the French model; excepting that the ancient appellations of *conſuls, ſenators*, and *tri*[illegible] were adopted, inſtead of the new [illegible] and *two Councils* (D). But this [illegible] freedom was rendered completely [illegible] — 324 Roman re-

(D) The character of a nation, like that of an individual, will not perhaps admit of a ſudden and total ch[illegible] This remark is exemplified in the French; who, even when they affect to aſſume the ſtern manners of R[illegible] cans, cannot diveſt themſelves of their frivolous and fantaſtical turn, and of that fondneſs for [illegible] which they were always diſtinguiſhed. The following account of the re-eſtabliſhment of th[illegible] by an author of reſpectability, who witneſſed the ſolemn farce, will amply confirm the truth [illegible]

"That the regenerated Roman people might be conſtitutionally confirmed in their [illegible] day was ſet apart ſolemnly to renounce their old government, and ſwear fidelity to the new. For the [illegible]tion of this ſolemnity, which took place on the 20th of March, an altar was erected, in the middle of the piazza of St Peter's, with three ſtatues upon it, repreſenting the French, Ciſalpine, and Roman Republics. Behind the altar was a large tent, covered and decorated with ſilk of the Roman colours, ſurmounted with a red cap, to receive the deputies from the departments who had been ſummoned to aſſiſt. Before the altar was placed an open orcheſtra, filled with the ſame band that had before been employed to celebrate the funeral honours of Duphot. At the foot of the bridge of St Angelo, in the piazza di Ponte, was erected a triumphal arch, upon the general deſign of that of Conſtantine, in the Campo Vacino, on the top of which was alſo placed three coloſſal figures, repreſenting the three republics. As a ſubſtitute for baſs-reliefs, it was painted in compartments in *chiara ſcura*, repreſenting the moſt diſtinguiſhed actions of Bonaparte in Italy. Before this arch was another orcheſtra.

"The ceremony in the piazza began by the marching in of the Roman legion, which was drawn up cloſe to the colonnade, forming a ſemicircular line; then came French infantry, and then cavalry, one regiment after another alternately, drawn up in ſeparate detachments round the piazza. When all was thus in order, the conſuls made their entrance, on foot, from the Vatican palace, where they had robed themſelves, preceded by a company of national troops and a band of muſic; and if the weather had permitted, a proceſſion of citizens, ſelected and dreſſed in *gala* for the occaſion, from the age of five years to fifty, were to have walked two and two carrying olive branches; but an exceſſively heavy rain prevented this part of the ceremony.

"Before the high altar, on which were placed the ſtatues, there was another ſmaller one with fire upon it. Over this fire the conſuls, ſtretching out their hands, ſwore eternal hatred to monarchies, and fidelity to the republic; and at the concluſion, one of them committed to the flames a ſcroll of paper he held in his hand, containing a repreſentation of all the inſignia of royalty, as a crown, a ſceptre, a tiara, &c.; after which the French troops fired a round of muſketry; and, at a ſignal given, the Roman legion raiſed their hats in the air upon the points of their bayonets, as a demonſtration of attachment to the new government: but there was no ſhouting—

French Revolution, 1798.

tion annexed to it, that for ten years the French General should possess a negative upon all laws and public acts. At first, however, the conquerors took care to place the government in the hands of the most respectable persons in the state favourable to democracy. But these men finding that they were merely to be employed as tools to plunder their fellow-citizens, for the emolument of their northern masters, soon renounced their odious dignities, and were succeeded by men of more compliant characters, and less scrupulous integrity. The whole public property was seized by the invaders, and contributions were levied without end. The property of the cardinals and others who fled was confiscated, and those members of the sacred college who remained were thrown into prisons, from which they could only escape by purchasing their freedom at a high price.

When this was done, and Generals and Commissaries had glutted themselves with wealth, quarrelled about a *just* division of the spoil, mutinied, and dispersed, other unpaid, unclothed, unprovisioned armies from the north, with new appointments, succeeded; and when at length, even by these *constitutional* means, nothing more was to be obtained, and artifice had exhausted every resource, the mask was put under the feet that had been long held in the hand; liberty was declared dangerous to the safety of the republic, the constituted authorities in-
325 Superseded by military despotism. capable of managing the affairs of the state, and military law the only rational expedient to supply their place. Thus at once the mockery of consular dignity was put an end to, the senators sent home to take care [illegible] and the tribunes to blend with the peo[illegible] represented. This new and pre[illegible] began its operations with nothing less [illegible] for the general welfare, than seizing the whole annual revenue of every estate productive of more [illegible] thousand crowns; two-thirds of every estate [illegible] more than five, but less than ten; and [illegible] of every inferior annual income.

[illegible] degenerated Romans could not have sub[illegible], or at least would not have assisted in forging their own chains, had not the same means been employed to eradicate from their minds every moral and religious principle, which had been formerly employed for the same purpose in Paris. In order that the spirit of equality might be more extensively diffused, a constitutional democratic club was instituted, and held in the hall of the Duke d'Altemp's palace. Here the new-born sons of freedom harangued each other on the blessings of emancipation; talked loudly and boldly against all constituted authority; and even their own consuls, when hardly invested with their robes, became the subjects of censure and abuse. The English were held as particularly odious, and a constant theme of imprecation; and this farce was so ridiculously carried on, that a twopenny subscription was set on foot to reduce what they were pleased to call the proud Carthage of the North.

French Revolution, 1798.

326 Methods employed to corrupt the Roman youth.

If this foolish society had had no other object in view than spouting for each other's amusement, bowing to and kissing a bust of Brutus which was placed before the rostrum (a ceremony constantly practised before the evening's debate), it would have been of little consequence to any but the idle, who preferred that mode of spending their time; but it had other objects of a very different tendency, more baneful, and more destructive to the peace and morals of society—that of intoxicating young minds with heterogeneous principles they could not understand, in order to supersede the first laws of nature in all the social duties; for there were not wanting men who knew how to direct the folly and enthusiasm of those who did not know how to direct themselves. Here they were taught, that their duty to the Republic ought ever to be paramount to every other obligation; that the illustrious Brutus, whose bust they had before them, and whose patriotic virtue and justice ought never to be lost sight of, furnished them with the strongest and most heroic example of the subordination of the dearest ties of humanity to the public good; and that, however dear parental affection might be, yet, when put in competition with the general welfare of society, there ought not to be a moment's hesitation which was to be preferred.

This sort of reasoning might perhaps have done no harm to the speculative closet metaphysician, who might have had neither father, nor mother, nor brother, nor sister, nor a chance of ever being thrown in the way to reduce his theory to practice; but with a people who knew of no other ties but such as depended on their religion and their natural feelings, without having been previously educated to discriminate, how far their reason might be deluded by sophistry, or upon what

---

no voluntary signs of approbation; nor do I believe that there ever was a show, in which the people were intended to act so principal a part, where so decided a tacit disapprobation was given as on this occasion.

"After the ceremony was concluded, the French officers, with the consuls and deputies from the departments, dined together in the papal palace on Monte Cavallo, and in the evening gave a magnificent ball to the exnobles and others, their partizans, which was numerously attended, yet with an exception to the houses Borghese, Santacroce, Altemp, and Cesarini: I believe not one distinguished family was present from desire or inclination: but it was now no longer time to accumulate additional causes for oppression; and he who hoped to save a remnant of his property, avoided giving occasion for personal resentment. At night the dome of St Peter's was illuminated, with the same splendour as was customary on the anniversary of St Peter's day. This was the second time of its illumination since the arrival of the French, having been before displayed on the evening of the solemn fete to honour the manes of Duphot, which, though not quite so opportune, was done to gratify the officers that were to leave Rome on the morrow.

"The day after this federation, the French published the Roman constitution in form, which was only a repetition of the one given to the unfortunate Venetians, consisting of 372 articles, and which I think unnecessary to transcribe, as it would only be giving what we have already had from time to time in translations made from their own."—*Duppa's Journal of the most remarkable Occurrences that took place in Rome,* upon the Subversion of the Ecclesiastical Government in 1798.

French Revolution, 1798. causes the permanent good of society depended, it had the most direct tendency to generate the worst passions, and to annihilate the best.

Young men were thus initiated to lose all respect for their parents and relations, and even encouraged to lodge information against them, with the hopeful prospect of being considered as deserving well, of what they were pleased to denominate, the republic; and by thus weakening or destroying the bonds of affection, the way was made smooth and easy to the destruction of every thing like what, in a state of civilization, is called character; doubtless, in order to prepare them the better to become the faithful agents of those whom they were thus educated to serve.

317 Monuments of ancient art exposed to sale.

The most remarkable curiosities of this celebrated city had already been conveyed to Paris; and as national vanity had now given place to avarice in the minds of the Directory, the remaining monuments of ancient or of modern art, with which Rome abounded, were sold by public auction. Advertisements (ε) were sent through Europe, offering passports to the natives of countries at war with France, if they should wish to become purchasers; and thus the wealthier inhabitants of the Roman territory not only saw themselves subjected to severe exactions, but they beheld with cruel mortification those objects now given up as a prey to vulgar speculation, and dispersed over the world, which had so long rendered their city the resort of all nations.

Such was the progressive conduct of the *Great Nation* towards an injured and oppressed people, whose happiness and dearest interests were its first care, and to whom *freedom* and *liberty* had been restored, that they might know how to appreciate the virtue of their benefactors, and the inestimable blessings of independence.

318 French ingratitude to Switzerland.

More sanguinary scenes were, in the meanwhile, taking place in Switzerland. That country had remained neutral during the contest in which France had lately been engaged; and had thus protected the weakest portion of her frontier, while the rest of it was assailed by the combined forces of Europe. The merit of this service was now forgotten, and the Directory resolved to render Switzerland one of their tributary states. Ambitious nations have in all ages found it an easy matter to devise apologies for invading the territory of their neighbours. The wealthier branches of the Swiss confederacy were in general governed by hereditary aristocracies. Some of the cantons had no government within themselves, but were the subjects of neighbouring cantons. In consequence of this circumstance, and of the contending privileges of different orders of men, popular insurrections were more frequent in Switzerland than in any country in Europe, though none was more equitably governed. When an insurrection took place in one canton, its government was frequently under the necessity of soliciting the aid of the government of an adjoining canton, or even of the neighbouring monarchs of France or Sardinia, to enable it to subdue its own rebellious subjects. A dangerous precedent was thus established; and as the French kings had formerly interfered in favour of the rulers, the republican Directory now interfered in favour of the subjects. The canton of Berne was sovereign of the territory called the *Pays de Vaud*. In this district discontents had always existed; and an insurrection, under the countenance of the French Directory, broke out towards the end of the year 1797. The government of Berne saw the dangerous nature of its own situation; and on the 5th of January issued a proclamation, commanding the inhabitants of the Pays de Vaud to assemble in arms, to renew their oath of allegiance, and to reform every abuse that might appear to exist in their government. A commission was at the same time appointed by the Senate or Sovereign Council at Berne to examine all complaints, and to redress all grievances. The proceedings of this commission, however, did not keep pace with the popular impatience; and the insurgents began to seize the strong places in their country. The government of Berne now resolved to reduce them by force, and sent troops against them; but their commander Weiss appears to have acted with much hesitation, if not with treachery. In the mean time, a body of French approached under General Menard. He sent an aide-de-camp with two hussars, with a message to General Weiss. On the return of the messengers, an accidental affray took place, in which one of the hussars was killed. This was magnified into an [illegible] breach of the law of nations. The French [illegible] and by the end of January obtained [illegible] whole Pays de Vaud. Still, ho[illegible] of Berne attempted to preserve [illegible] voured to prepare for war. The soldiers [illegible] ed the French hussar were delivered up, [illegible] were begun, and a truce entered into with [illegible] Brune, who succeeded Menard in the command of the French troops in the Pays de Vaud. [illegible] motions were breaking out in all [illegible] was made to quiet the minds [illegible] might be induced to unite [illegible] sion. Fifty two deputies from the different districts were allowed to sit in the Supreme Council of Berne, and a similar measure was adopted by the cantons of Zurich, Lucerne, Fribourg, Soleure, and Schaffhausen. An army of 20,000 men was at the same time assembled, and intrusted to the command of M. d'Erlach, formerly field-marshal in the French service. But disaffection greatly prevailed in this army, and the people could not be brought to any tolerable degree of union. The French knew all this, and demanded a total change of government. M. d'Erlach, dreading the increasing tendency to desertion among his troops, requested leave to dissolve the armistice. It was granted by the government, and immediately recalled. But the French now refused to negociate; and on the 2d of March, General Schawenberg, at the head of 13,000 men, entered Soleure.

(ε) A copy of an advertisement, issued on this occasion by what was called *The Administration of Finances and Contributions of the French Republic in Italy*, is to be found in *Nicholson's Journal of Philosophy, Chemistry, and the Arts, for May* 1798. The advertisement is dated at Rome, 28th Feb. 1798. A copy of it was sent by Hubert, the agent of the French administrators, to Mr Trevor the British minister at Turin, and by him was transmitted to England.

French Revolution, 1798.

Soleure. Friburg was afterwards reduced by Brune, and the Swiss army retreated. The government of Berne was in consternation, and decreed what was called the *landsthurm*, or rising of the people; which, in cases of emergency, was authorised by their ancient customs.

330 Consternation of the government, and capitulation of Berne.

The people accordingly assembled; and their first act was to dissolve the government, and to offer to dismiss the army, on condition that the French troops should proceed no farther. This offer was refused, unless a French garrison should be received into Berne, and the invaders continued to advance. The regular troops under M. d'Erlach were reduced by desertion to 14,000. The rising of the people had indeed supplied him with numbers, but there was no time for arranging them. On the 5th of March he was attacked, and driven from the posts of Newenbeg and Favenbrun. He rallied his troops, however, at Uteren, where they made a stand for some time. They renewed the contest at Grauholtz without success, and were driven from thence about four miles farther to the gates of their capital. Here the Swiss army made a last and bloody effort. Being completely routed, they murdered many of their officers in despair, and among others their commander M. d'Erlach. The slaughter on both sides is said to have been nearly equal; but the French succeeded in obtaining possession of Berne by capitulation on the evening of the day on which these battles were fought. Upon the capture of this city, the other more wealthy and populous states submitted to the French; but the poorer cantons, who had least to lose, made a terrible [illegible] in defence of their small possessions, and the inde[illegible] country. They even at first com[illegible] to retire with the loss of 3000 [illegible] overpowered by the superior [illegible] military skill of the French army. Swit[illegible] was treated as a conquered country. Its pub[illegible] were seized by the French, heavy contri[illegible] were levied, and a new constitution, in imita[illegible] France, was imposed.

331 [illegible] land treated as a conquered country.

[illegible] continued to encroach upon [illegible] other nations, they were not likely [illegible] freedom of their countrymen at home. In [illegible] of April, a third of the legislature was changed. Francis de Neufchateau went out of the Directory by ballot, and Treilhard was chosen in his stead. The Directory had made great efforts to influence the elections in favour of their friends, but with little success. They prepared therefore to preserve the legislature in subjection to them by a new violation of the constitution. On the 2d of May they complained to the Council of Five Hundred of the plots of anarchists and royalists; by which they alleged that the elections had in many places been made to fall on men hostile to the Republic. On the 7th a committee made a report upon this message, and proposed that the proceedings of many electoral assemblies should be totally or partially annulled, according to the characters of the persons they had chosen. General Jourdan, and some others, ventured to oppose this plan as utterly inconsistent with the freedom of election, and as proceeding upon alleged intrigues of conspirators against the Republic, while no conspiracy had been proved to exist. But the majority agreed to the proposal of the committee, and arbitrarily annulled the whole elections in six or seven departments, besides the particular elections of a great number of individuals.

332 The Directory violates the constitution.

The Directory now carried into effect the most fatal of all their projects, that of sending a powerful army to the east to seize upon Egypt, and from thence to attack the empire which Britain has acquired in India. The treaty with Austria had no sooner been signed at Campo Formio, than the Directory excited the expectation of France and of all Europe, by loudly proclaiming their determination to invade Great Britain. They sent troops into their own western departments, called them the *Army of England*, and appointed Bonaparte their commander in chief. This officer, in the mean time, had resided during the winter at Paris. Here he seems to have endeavoured to guard against the jealousy of government, and the envy of individuals, by passing his time in retirement, and assuming the character of a man of letters. He procured himself to be elected a member of the National Institute; but so seldom did he appear abroad, that when he attended some of its public sittings his person was altogether unknown to the spectators. Greedy of renown, but aware that it ultimately depends upon the labours and the approbation of the learned, he never failed, when called into military service, to remind this order of men of his alliance with them, by adding to his name at all proclamations and dispatches the designation of *Member of the National Institute*.

French Revolution, 1798.

333 Project of an expedition to Egypt and India.

Whether the expedition to Egypt was now suggested by Bonaparte himself, or whether it was not a snare by which the present rulers of France imposed upon the vanity of an enterprising young man, to enable them to get quit of him and his veteran army, is not known. It is very possible, however, that Bonaparte might neither be the deviser nor the unconscious victim of this plan; but that he might account himself more safe abroad, upon the most hazardous expedition, than exposed at home to the malice of a government that had become jealous of his reputation, and was by no means scrupulous in its conduct.

The projected invasion of Egypt was conducted with much secrecy. The world was amused with tales of monstrous rafts to be constructed to convey the army of England over into Britain. To favour the deception, Bonaparte made a journey to the western coast. In the mean time, the fleet was preparing at Toulon, and troops assembling in its neighbourhood. When all was in readiness, Bonaparte embarked with 40,000 of the troops that had fought in Italy. On the 9th of June he arrived at the island of Malta, and contrived to quarrel with the Grandmaster, because he refused to admit so large a fleet all at once into his ports to water. The French General immediately landed his troops in different quarters, and endeavoured to reduce the island. The knights were divided into factions. Many of them, as is now well known, were of the order of ILLUMINATI, and of course prepared to act the part of traitors. After making a very feeble resistance, the Grandmaster proposed a capitulation; and thus was treacherously surrendered, in a few days, a fortress which, if defended by faithful troops, might have held out for as many weeks against all the forces of the French Republic. Bonaparte, after leaving a garrison of 4000 men in the island, sailed on the 21st of June for Alexandria.

334 Preparations for it conducted with secrecy.

335 Conquest of Malta.

In the mean time, Rear-admiral Nelson, who, in the station of Commodore, had signalized himself in a very high degree under Lord St Vincent, had been dispatched in quest of him from the British fleet, which still blockaded

336 Admiral Nelson fails in quest of Bonaparte.

French Revolution 1798

blockaded Cadiz. Not knowing the object of the French expedition, the British Admiral sailed first to Naples; and having there been informed of the attack upon Malta, he directed his course to that island. By the time he arrived there, however, Bonaparte had departed. Conjecturing now that Alexandria might be the destination of the French troops, he sailed thither; but they had not been seen in that quarter, and he therefore went eagerly in search of them to other parts of the Mediterranean. Bonaparte, in the mean while, instead of steering in a direct line for Alexandria, had proceeded slowly, with his immense train of nearly 400 transports, along the coast of Greece, till he arrived at the eastern extremity of the island of Candia. Here he suddenly turned southward; and in consequence of his circuitous course, did not arrive at the coast of Egypt till Admiral Nelson's fleet had left it. He landed his troops; and on the 5th of July took by storm the city of Alexandria. The inhabitants defended themselves very desperately, but without skill; and for some time a scene of barbarous pillage and massacre ensued. The transports that had conveyed the army were now placed within the inner harbour of Alexandria, and the ships of war under Admiral Brueys cast anchor in a line close

337 Conquests of Bonaparte in Egypt.

along the shore of what proved to them the fatal Bay of Aboukir. The army proceeded to the Nile, and ascended along the banks of that river, suffering great hardships from the heat of the climate. They were met and encountered by the Mamalukes, or military force that governed Egypt; but these barbarians could not resist the art and order of European war. Cairo was taken on the 23d of July. On the 25th another battle was fought; and on the 26th the Mamalukes made a last effort in the neighbourhood of the celebrated pyramids for the preservation of their empire. Two thousand of them were killed on this occasion, 400 camels laden with their baggage were taken, along with 50 pieces of cannon.

A provisional government was now established in Egypt. Proclamations were issued in the Arabian tongue, declaring that the French were friendly to the religion of Mahomet, that they acknowledged the authority of the Grand Signior, and had only come to punish the crimes committed by the Mamalukes against their countrymen trading to Egypt. Thus far all had gone well; but on the 1st of August the British fleet appeared at the mouth of the Nile; and the situation of the French fleet having been discovered, Admiral Nelson

338 Admiral Nelson attacks and destroys the French fleet.

prepared for an attack. In number of ships the fleets were equal; but in the number of guns and weight of metal the French squadron had the superiority. It was drawn up, too, in a form which suggested to its ill-fated commander the idea of its being invincible; but remaining at anchor, the British Admiral was enabled, by running some of his ships between those of the enemy and the shore, to surround and engage one part of their fleet, while the rest remained unemployed and of no service. In executing this plan of attack, a British ship, the Culloden, run aground; but this accident only served as a beacon to warn the others of the spot that ought to be avoided. The battle commenced at sunset, and was continued at intervals till daybreak. At last, nine sail of the French line were taken; one ship of the line was burned by her own commander; a frigate was burned in the same manner, to prevent her being taken. The French Admiral's ship L'Orient took fire, and blew up during the action, and only a small number of her crew of 1000 men escaped destruction. Two French ships of the line and two frigates were saved by a timely flight (F).

No naval engagement has in modern times produced such important consequences as this. 339 Consequences of his victory.
The unexampled military efforts made by France had gradually dissolved the combination which the princes of Europe formed against her. By the train of victories which Bonaparte had gained, the house of Austria, her most powerful rival, had been humbled and intimidated. The whole continent looked towards the new Republic with consternation; and when the Directory seized upon Rome and Switzerland, none were found hardy enough to interpose in their favour. The current of affairs was now almost instantaneously altered. Europe beheld Bonaparte, with his *invincible* army, exiled from its shores, and shut up in a barbarous country, from which the triumphant navy of Britain might for ever prevent his return. The enemies of France could not beforehand have conceived the possibility of the event which was now realised; and the hope was naturally excited of being able to form a new and more efficient coalition against a government which had so grossly abused the temporary prosperity it had enjoyed. The northern powers began to listen to the proposals made to them by Great Britain for commencing hostilities [illegible] the Italian states prepared to [illegible] independence. The court of Na[illegible] ly avowed its joy on account o[illegible] of the French fleet. The king [illegible] meet Admiral Nelson on his return [illegible] luminations took place in the capital, and vi[illegible] parations were made for war. The Grand S[illegible] had possessed of late little authority [illegible] perhaps have been induced to [illegible] that province rather than [illegible] war, now entered into close [illegible] engaged in hostilities against the French. [illegible] tan had stipulated for the aid of a French [illegible] the British in India; but Bonaparte, on [illegible] possession of Suez and the other Egyptian ports on the Red Sea, found no shipping there fit to transport his army to the Indian peninsula. Instead of proceeding therefore upon any splendid scheme of farther conquest, he was compelled to remain in his present situation, and to contend for existence against the whole force of the Ottoman empire.

The French at this time did not venture to send forth any large fleet upon the ocean; but wherever their smaller squadrons appeared, the fortune of Britain overpowered them there no less than it had done in the Mediterranean. 340 Rebellion in Ireland.
They had long promised aid to the disaffected party in Ireland; but weary of fruitless expectation, the Irish had during this summer broken out into rebellion, without waiting the arrival of the troops whom the Directory had engaged to send to their assistance. While the rebellion was at its height, and although the insurgents for some time occupied the sea port of Wexford, the French did not arrive. Afterwards,

(F) The two ships of the line and one of the frigates have been since taken.

French Revolution. 1798.

wards, however, when the rebellion had been totally subdued, they attempted to elude the vigilance of the British fleet, and to land men in small parties. On the 22d of August, General Humbert came ashore at Killala, at the head of about 1100 men. Even this small party might have been dangerous had it arrived a month earlier; and it actually produced very serious alarm. It consisted of men selected with great care, and capable of enduring much fatigue. They were joined by a few of the most resolute of the discontented Irish in the neighbourhood, and speedily defeated General Lake, who advanced against them with a superior force, taking from him six pieces of cannon. They next marched in different directions, for the purpose of raising the people, and maintained their ground in the country during three weeks. Finding, however, that he was not seconded by additional troops from France, that the rebellion in Ireland had been fully subdued, and that 25,000 men under Lord Cornwallis were closing round him, Humbert dismissed his Irish associates; and four days thereafter, having encountered one of the British columns in his march, he laid down his arms. Now, when it was too late, the Directory was very active in sending troops towards Ireland; but all their efforts were defeated by the superiority of the British navy.

341 *Feebly supported by the Directory.*

342 *Whose efforts are defeated by the British navy.*

On the 12th of October, Sir John Borlase Warren took La Hoche, a ship of 84 guns, and four frigates, attempting to reach Ireland with nearly 3000 men on board. The other ships belonging to the French squadron, which conveyed 5000 men in all, contrived to [illegible] by sailing round by the north of the [illegible] 20th of the same month another fri[illegible] Ireland was taken; and the French [illegible] was completely occupied by the [illegible] at last compelled to desist from their [illegible]

[illegible] the treaty of Campo Formio had been [illegible] a congress of ministers from the French Di[illegible] German princes, had been nego[illegible] treaty between France and the em[illegible] negociations terminated in nothing, [illegible] and uninteresting during their pro[illegible] unnecessary to enter into a detail of the steps by which they were conducted. The intended result of them had been previously arranged between the Emperor and the Directory in the secret convention of Campo Formio, which has been already mentioned.

343 *Negociations at Rastadt.*

That the articles of this convention might be concealed, the French ministers at Rastadt formally brought forward their proposals in succession for the discussion of the German deputies. The French demanded that the Rhine should be the boundary of their Republic. The Germans resisted this. References were made to the diet of Ratisbone, and long discussions and negociations took place among the different princes. When it was found that little was to be expected from the protection of Austria, the German deputies at Rastadt were instructed to offer one half of the territory demanded. This offer was refused, and new negociations took place. The other half was at last yielded up, and a long discussion commenced about the debts due by the ceded territory, which the French refused to pay. The tolls upon the river, and upon the rivers flowing into the Rhine, also gave rise to much altercation. It was even a matter of no small difficulty, after all, to determine the precise boundary of France; whether her territory should extend to the left bank, the right bank, or the thalweg, that is, the middle of the navigable channel of the river. It became also a question how those princes ought to be indemnified who lost their revenues or territories by the new acquisitions of France; and it was at length agreed that they should receive portions of the ecclesiastical estates in Germany.

These discussions, conducted with endless formality and procrastination, still occupied the congress at Rastadt; but it now became gradually more probable that no treaty would be concluded at that place. Austria began to strengthen her armies in all quarters. Russia, that had hitherto avoided any active interference in the contest, placed a large body of troops in British pay, and sent them towards the German frontiers. The king of Naples avowedly and eagerly prepared for war. This impatient monarch, resolving to attack without delay the French troops who occupied the Roman territory, procured General Mack and other officers from the court of Vienna to assume the command of his army. Without waiting, however, till Austria should commence the attack, he rashly began the war alone and unaided, excepting by the British fleet, and thus drew upon himself the whole force of the French Republic. The Directory did not suspect such imprudent conduct on the part of this prince; and accordingly, when General Mack entered the Roman territory, at the head of 45,000 men, the French troops in that quarter were altogether unequal to the contest. A French ambassador still resided at Naples when this event took place, and war was not declared. When the French General Championnet complained of the attack made upon his posts under these circumstances, he was informed in a letter by General Mack, that the king of Naples had resolved to take possession of the Roman territory, having never acknowledged its existence as a Republic; he therefore required the French quietly to depart into the Cisalpine states; declaring, that any act of hostility on their part, or their entrance into the territory of Tuscany, would be regarded as a declaration of war.

344 *Preparations for war on the Continent.*

Championnet finding himself unable to resist the force now brought against him, actually evacuated Rome. He left, however, a garrison in the castle of St Angelo, and endeavoured to concentrate whatever troops he could hastily collect in the northern extremity of the Roman state. Towards the end of November, General Mack entered Rome without opposition.

345 *The Neapolitans take possession of Rome.*

When these events came to be known at Paris, war was immediately declared against the king of Naples, and also against the king of Sardinia. This last prince had made no attack upon France; but he was accused by the Directory, in their message to the Councils, of *disaffection* to the Republic, and of *wishing* to join the king of Naples in his hostile efforts. This accusation could not well be false. From the period of Bonaparte's successful irruption into Italy, the king of Sardinia had felt himself placed in the most humiliating circumstances; his most important fortresses were occupied by the French; they levied in his country what contributions they thought fit; and when they recently required him to receive a garrison into his capital, he found himself unable to resist the demand. Even now, when they performed the useless ceremony of declaring war, he could make no effort in his own defence, and quietly

346 *Hard fate of the king of Sardinia.*

French Revolution 1798.

quietly gave them a formal reſignation in writing of his whole continental dominions, conſenting to retire to the iſland of Sardinia.

In the mean time, the conteſt with Naples was ſoon decided. The French on their retreat were much haraſſed by the people of the country. The Neapolitan troops regarded them with ſuch animoſity, that they ſcarcely obſerved the modern rules of war towards the priſoners who fell into their hands. Even their leaders ſeemed in this reſpect to have forgotten the practice of nations; for when General Bouchard, by order of General Mack, ſummoned the caſtle of St Angelo to ſurrender, he declared, that he would conſider the priſoners of war and the ſick in the hoſpitals as hoſtages for the conduct of the garriſon; and that for every gun that ſhould be fired from the caſtle, a man ſhould be put to death. It cannot well be imagined that the Neapolitan officers would have acted in this vehement manner, had they not expected countenance and ſupport from the immediate co-operation of Auſtrian troops.

347 Naples conquered by the French.

In their hopes from this quarter, however, they were completely diſappointed. Mindful of her recent calamities, and attentive only to her own aggrandiſement, Auſtria ſeems ſtill to have expected more from negociation than from war, and the territory of Naples ſoon fell into the hands of the French. Such indeed was the terror of the French name in Italy, or ſuch was the diſaffection or cowardice of the Neapolitan troops themſelves, that they were beaten by one-fourth of their number in different engagements, at Terni, Porto Fermo, Civita Caſtellana, Otricoli, and Calvi. At the commencement of the conteſt, a body of Neapolitans, with the aſſiſtance of the Britiſh fleet, had been landed at Leghorn, for the purpoſe of taking the French in the rear: but they, diſregarding this attempt on the part of ſuch an enemy, preſſed on towards Naples. By degrees, General Mack's army being reduced by the reſult of the battles which it fought, and by deſertion, to 12,000 men, he found it neceſſary to adviſe the king and royal family of Naples to take refuge on board the Britiſh fleet. They did ſo; and arrived at Palermo, in Sicily, on the 27th of December, in the Britiſh Admiral Lord Nelſon's ſhip. General Mack, in the mean time, requeſted an armiſtice, to afford an opportunity for making peace; but this was refuſed. Being driven from Capua, which is the laſt military poſt of any ſtrength in the Neapolitan territory, and his life being in no ſmall danger from the diſaffection of his own troops, he at laſt found it neceſſary to ſeek for ſafety, by ſurrendering himſelf, along with the officers of his ſtaff, to the French General. The governor of Naples, in the mean time, offered to the French a contribution in money, if the commander in chief would conſent to avoid entering that city. The offer was accepted, and the invading army remained at Capua. General Serrurier, on the 28th of December, at the head of a column of French troops, expelled the Neapolitans from Leghorn, and took poſſeſſion of that place. So far as the efforts of regular armies are to be conſidered, the war might now therefore be regarded as brought to a termination; but the French had ſpeedily a new and unuſual enemy to contend againſt.

1799.

From the mildneſs of the climate, and the fertility of the ſoil, human life can be ſuſtained in the ſouthern parts of Italy with fewer efforts of induſtry than in almoſt any other country in Europe. Hence ariſes a general propenſity to idleneſs, which is increaſed by the numerous charitable inſtitutions to which the Roman Catholic religion gives riſe. In the city of Naples there had long exiſted a body of perſons under the denomination of *Lazzaroni* or Beggars, amounting to the incredible number of from thirty to forty thouſand men, who did nothing, and ſubſiſted merely by charity, or by ſuch ſhifts as occaſionally occurred to them. One of theſe frequently was the menacing the ſtate with an inſurrection, in caſe their wants were not inſtantly ſupplied; which uſually drew from a feeble adminiſtration very liberal diſtributions of money and proviſions. On the preſent occaſion they demonſtrated abundance of loyalty; but the king had thought fit to avoid entruſting his ſafety to ſuch defenders. During the confuſion which followed the flight of the court and the approach of the French army, the Lazzaroni became mutinous.

French Revolution, 1799.

348 The Lazzaroni riſe againſt the French.

They heard that the French aboliſhed, wherever they came, all thoſe monaſteries and other religious eſtabliſhments which are the great ſources of public charity. The Lazzaroni, therefore, conceived the moſt violent hatred againſt them, and againſt all who were ſuſpected of favouring opinions hoſtile to royal government. In the beginning of January they began to ſhew ſymptoms of diſcontent, and in a few days broke out into open inſurrection. The members of the government left by the king, overcome by habitual terror of the Lazzaroni, conſulted merely their own perſonal ſafety, and made no effort to preſerve the public tranquillity. Prince Militorni had gained [illegible] plauſe on account of his vigorous def[illegible] gainſt the French. The Lazzar[illegible] him their commander in chief; [illegible] to reſtrain their violence and love of plunder. They declared hoſtility againſt the French, and all the adviſers of the armiſtice. They broke open the priſons, and put to death all thoſe who were confined on account of political offences againſt the royal government. They next ſpread t[illegible] in ſearch of thoſe perſons [illegible] they conſidered as favourable to the invaders, and committed murder and robbery in all quarters, concluding by burning the houſes of thoſe accounted diſaffected. An attempt was made by a conſiderable body of the inhabitants, who thought themſelves in the greateſt danger, to reſiſt their fury, by fortifying the convent of the Celeſtine, and retiring thither; but the Lazzaroni, after encountering the fire of cannon and of muſketry, ſucceeded in ſtorming the place, and deſtroyed all who had taken refuge there. Their power and their fury were now equally boundleſs, and the city became in many quarters a ſcene of maſſacre and pillage. Prince Militorni, therefore, went to Capua, and requeſted Championnet to reſcue Naples from utter ruin by occupying it with his army. For this purpoſe it was arranged, that a column of French troops ſhould ſecretly advance by a circuitous march, and ſuddenly enter the city from the oppoſite quarter. Before this plan could be fully executed, the Lazzaroni had adopted the daring reſolution of attacking the French within the fortifications of Capua. Accordingly two-thirds of them marched out upon this enterpriſe, and ſpent the 19th and 20th of January in attempting to take Capua by aſſault. Multitudes of theſe men here periſhed by the artillery of the place; for the

349 Their own [illegible]

French.

French Revolution, 1799.

French, to favour the capture of Naples by the party that had been sent eastward for that purpose, avoided making any sally, and remained upon the defensive. The Lazzaroni at Capua, however, having learned on the 21st that a French column had marched to Naples, and approached the gates, suddenly returned to the assistance of their brethren in the capital. They were closely pursued by the French; but they had leisure, nevertheless, to barricade the streets, and to form themselves into parties for the defence of different quarters. A dreadful and sanguinary contest now ensued, which lasted from the morning of the 22d to the evening of the 23d of January. The Lazzaroni, with some peasants who had joined them, disputed obstinately every spot of ground; and by the energy which they displayed, cast a severe reproach upon the feeble and unskilful government, which had not been able to direct in a better manner the courage of such men. At length, after having been gradually driven from street to street, the Lazzaroni rallied for the last time at one of the
350 gates of the city, where they were nearly exterminated.

350 They are nearly exterminated.

The inhabitants rejoiced on account of their own escape from immediate ruin; and while the French armies found themselves become odious in all the other countries which they had entered, they here found themselves, from the peculiar circumstances of the case, received with unfeigned welcome, in a city which holds the third place in population and splendour among the capitals of Europe.

This may be regarded as the last triumph enjoyed by the Directory. The consequences of their conduct [illegible] gathering fast around them. They were de[illegible] home; not only from the violations [illegible] to the constitution of their country, but also from the manner in which they conducted public affairs in detail. They set no bounds to their [illegible], or to the exactions with which their agents [illegible] the conquered countries. Championnet, ashamed [illegible] which the commissaries of the Directory [illegible], attempted in Italy to restrain [illegible] consequence was, that, upon the complaint of the commissary [illegible]poult, he was deprived of his command, and thrown into prison. Scherer, the minister of war, was appointed his successor. Under him the rapacity of the agents of government, and the embezzlement of the public stores, was carried to its
351 height. The numbers of the armies were suffered to decline, that the Directory, the commissaries, and the generals, might become rich. Thus the state was left totally unprepared against the storm which was now rapidly gathering from abroad. Still, however, France was feared by the neighbouring nations, to whom the present state of her internal affairs was obscurely known. Though an army of 45,000 Russians had advanced to the aid of Austria, yet that Cabinet hesitated to declare war. Prussia was eagerly solicited by Britain to take up arms against France, and large pecuniary aid was offered; but Sieyes, the Directory's ambassador at Berlin, artfully contrived to defeat this negociation, and to counteract the unpopularity of his country in Germany, by publishing the secret convention at Campo Formio, which we have already mentioned. This treaty demonstrated so clearly to the German princes the utter unconcern with which their independence and their interests were regarded by the head of the empire, that no steady co-operation with Austria could henceforth be expected from them. The greater number of them, therefore, resolved to maintain their neutrality under the protection of Prussia.

351 Rapacity of the Directory.

On the 2d of January, the French ministers at Rastadt presented a note to the congress, in which they intimated, that the entrance of Russian troops into Germany, if not resisted, would be regarded by them as a declaration of war. Some negociation took place in consequence of this note, but no satisfactory answer was returned. On the 26th of that month, the strong fortress of Ehrenbreitstein surrendered, after having remained under blockade since the conclusion of the treaty of Campo Formio. By the possession of this place, and of Mentz and Dusseldorf, France was now rendered very formidable on the Rhine. As she possessed also the strong country of Switzerland, and all the fortified places of Italy, she was well prepared, not only for defence, but for active operation; for it is now known, that the conferences of Rastadt were purposely protracted, by orders from the Directory, till the French armies should be ready to take the field with advantage against an enemy whose conduct betrayed the most culpable tardiness. At this time Jourdan commanded 352 on the Upper Rhine from Mentz to Huningen; Massena occupied with an army the eastern frontier of Switzerland towards the Grison country; Scherer was commander in chief in Italy; Moreau acted as general of a division under him; and Macdonald commanded the troops that occupied the territory of Rome and Naples. But these armies that kept in subjection, and were now to defend so many countries, scarcely amounted to 170,000 men in all, and were far outnumbered by the armies which Austria alone, without the aid of Russia, could bring into the field. The Directory, however, confiding in the unity of its own plans, in the undecided politics of the court of Vienna, and in the consequent slow movements of the Imperial armies, was eager to renew the war; and the two Councils, on the 13th of March, declared France to be at war with the Emperor of Germany and the Grand Duke of Tuscany. The war, however, had already been begun. On the 1st of March Jourdan crossed the Rhine at Strasburg, and occupied several strong positions in Swabia. Manheim was taken, and Philipsburg summoned to surrender by Bernadotte (G), while St Cyr entered Stutgard. On the 4th of March the Austrians crossed the Lech, under the command of the Archduke Charles, to oppose this army. Massena advanced into the territory of

French Revolution, 1799.

352 War renewed on the Rhine.

(G) This summons was conceived in very extraordinary terms, and cannot be accounted for but upon the supposition that Bernadotte believed the Austrian officers infected with French principles. He calls upon the commander of the fortress to surrender without resistance, and thus violate the trust reposed in him by his sovereign. He tells him, that a discharge of his duty would produce the *defection of his officers and men*. He warns him of the folly and danger of leading troops to action *against their will*; and, lastly, he threatens him with *vengeance* if he should *dare to resist!*

French Revolution, 1799.

of the Grifons; and furprifing a ftrong body of Auftrians, took them all prifoners, together with their General Auffenburgh, and the whole of his ftaff, after a defperate refiftance under the walls of *Coire*. The reduction of the Grifons was the confequence of this victory.

353 And in Switzerland.

But in order to complete the plan of the French, which was to effect a junction with their two armies, that of Maffena in Switzerland with that of Jourdan in Germany, it was neceffary to carry the important poft of Feldkirch, which was occupied by the Auftrian General Hotze, whofe line extended from the frontiers of the Grifons, to the north-eaft by the Vorelberg, to the eaftern extremity of the Lake Conftance. Vigoroufly repulfed in his firft attack, Maffena renewed it, five different times, with frefh forces, and increafed impetuofity. But all could not avail againft the fteady bravery of the Auftrians, who drove back the affailants with immenfe flaughter. The French, however, being in poffeffion of the Grifons, the invafion of the Engadine, and the county of Bormio, by a divifion of the army of Italy cantoned in the Valteline, under the orders of General Cafabianca, was facilitated. The Auftrians, too weak in that quarter to refift them, retreated into the Tyrol, whither they were purfued by the French, who forced fome of the defiles by which the entrance of that country was defended, and extended their deftructive incurfions as far as Glurenz and Nauders.

Meanwhile the van-guard of the main army of the Imperialifts pufhed forward to meet the enemy. On the 20th of March it was attacked by Jourdan, who drove in the outpofts; but on the following day that general was himfelf attacked in the centre of his army, driven from his pofition, and compelled to retire during the night to Stockach. Both parties now prepared for a decifive engagement. On the 24th, the Archduke encamped before Stockach, with his right wing towards Nellenburg, and his left near Wallenweis. On the 25th, at day-break, the French army began the attack. They directed their chief efforts againft the right wing of the Auftrians commanded by General Meerfeldt. The battle was long and obftinate. From five o'clock in the morning till paft one of the afternoon, its termination remained extremely doubtful. The French fucceeded in their attempt againft General Meerfeldt. His pofition was forced, and he retreated into a wood between Liptingen and Stockach. Here he renewed the combat without fuccefs. He was gradually driven to the extremity of the wood, though it is a German mile in breadth. The left wing of the Auftrians, however, had in the mean time maintained its ground, and reinforcements were fent from it to General Meerfeldt. With the affiftance of thefe he at laft fucceeded in making a ftand, and even obliged the French to retire in their turn. At length, about two o'clock, the French found it neceffary to withdraw from this quarter. The battle, however, was continued in different points till night came on. The French remained upon the ground where they had begun the attack, and they even retained 4000 prifoners whom they had taken during the various movements of the day. The refult of the battle, upon the whole, however, was fatal to their affairs. Their lofs was fo great, and the fuperiority of the Auftrians fo manifeft, that Jourdan dared not to hazard another engagement. On the following day he retired to Weiller near Dutlingen; and finding his army altogether unequal to offenfive operations, he fent back one part of it to cover Kehl and Strafburg, while he withdrew with the other towards Switzerland. This event compelled Maffena, who was preffing upon Tyrol and the Engadine, to return to the defence of Switzerland. He was immediately intrufted with the chief command of the troops in this quarter, in the room of Jourdan, who was removed. The Auftrians continued to advance in every direction, and immediately occupied the whole of the right, or German fide, of the Rhine, from the lake of Conftance to Mentz.

354 The French are defeated in Swabia.

355 And in Italy.

In Italy the fuccefs of the Auftrians was equally confpicuous, notwithftanding the treachery of the French in attacking them before the expiration of the truce. The attempt of the latter to force the advanced pofts of the former, on the 26th of March, at Santa Lucia and Buffelango, was rendered abortive; and at Legnago, the Auftrian general, Kray, obtained a complete victory, and compelled them to feek protection under the walls of Mantua. On the 5th of April, the Auftrians again attacked them in their pofition at Memiruolo, which lies on the road from Mantua to Pefchiera, and compelled them, after an obftinate conflict, once more to retreat. The lofs of the French in thefe different actions was undoubtedly great; but it is probably overrated at 30,000 men killed, wounded, and taken.

The fuccefs of the Auftrians, however, was not cheaply purchafed. Scherer, who commanded the French army, gained over them, at firft, fome advantages, which, had he known how to [illegible] might have given a different turn [illegible] One divifion of his army had [illegible] ftrian pofts on the 26th of [illegible] prifoners; but the other divifion [illegible] withdrew his troops from their advanced pofition, [illegible] thus relinquifhed the advantage which he had [illegible] Even on the 5th of April, Moreau's divifion [illegible] ed prodigies of valour, and took [illegible] prifoners; but from the [illegible] had been made by Scherer, [illegible] ported, and the victory of the Auftrians [illegible] Kray now quickly drove the French from [illegible] and compelled them, after having fuftained [illegible] to relinquifh their ftrong holds on the [illegible] and the Adige, and to retreat to the Adda.

356 Moreau fortifies his camp.

On the banks of this river, rendered remarkable for the dear-bought victories which Bonaparte had obtained at the bridge of Lodi, the French general Moreau, to whom the Directory had given the chief command of their army, prepared to make a vigorous defence. The military talents of this man had been rendered unqueftionable by his celebrated retreat through a hoftile country, and before a victorious army ably commanded. On the prefent occafion he did not belie his former character. Nothing that could give courage or confidence to his troops was neglected. Entrenchments were thrown up wherever the river was confidered as paffable; and a fituation, remarkably ftrong by Nature, was ftrengthened by every means which art could fupply.

Before this period, a confiderable body of Ruffians had joined the Imperialifts; and the chief command of the allied army was now affumed by Field Marfhal Suwarrow Rimnifki. This celebrated leader, whofe character

French Revolution 1799.

357 Marshal Suwarrow

racter every democrate labours to misrepresent, had entered into the army at the age of twelve, and risen from the ranks to the station which he now holds, of Generalissimo of the Russian armies. Possessed of strong natural talents, he had likewise the benefit of an excellent education, and is said, by those who are personally known to him, as well as acquainted with the state of literature in Russia, to be one of the best classical scholars of all the natives of that great empire. He had studied, in early life, mathematics and natural philosophy, as branches of science absolutely necessary to the man whose highest ambition is to become a great commander; and his knowledge of the learned, as well as of the fashionable languages, has enabled him to avail himself of all that has been written either by the ancients or the moderns on the art of war. This art has indeed been his chief study from his youth; it has been at once his business and his amusement.

Possessed with his countrymen, in general, of the most undaunted courage, and formed by Nature to endure the greatest fatigue, it is not surprising, that with all these advantages Suwarrow should have long ago acquired the character of one of the ablest generals of his time. It is indeed true, that, till the opening of the campaign of 1799, he had distinguished himself only against the Turks, whom we are too apt to despise, and against the Poles when divided among themselves; but let it be remembered, that the enthusiastic courage of those same Turks had found employment for the talents of some of the ablest generals in Europe, a Laudohn and a Cobourg; and that the Polish armies which Su[illegible] were united by the strongest of all [illegible] that they must conquer or perish. [illegible] known to Frederic the Great, that [illegible] talents of the Russian hero in the [illegible] and the attention of all Europe was [illegible] towards the quarter where those talents were [illegible] in the support of social order, and [illegible] man. His operations in [illegible] the highest expectations which [illegible]. At an age considerably [illegible] he began a campaign not less remarkable [illegible] than any which had gone before it since the commencement of the French revolution. We are by no means prepared, however, to do justice to the various military efforts which were now made, or to explain clearly the means employed to insure success. If the work entitled the *History of Suwarrow's Campaigns* be deserving of credit, the superiority of that commander over his rivals and opponents seems to have at all times consisted principally in the promptitude with which he formed his plans, and the rapidity with which he carried them into execution. It is likewise said to be a maxim of his, always to *commence* the attack when he sees a battle inevitable, from the persuasion that the ardour of the attacking army more than counterbalances the advantage of ground, if that advantage be not very great. Such was certainly the principle upon which he acted at present.

358 Attacks him in his intrenchments,

On the 24th of April the combined army advanced to the Adda; and having driven in Moreau's outposts, Suwarrow resolved, on the 26th, to attack him in his entrenchments. For this purpose, while the shew of an attack was maintained along the whole line, a bridge was secretly thrown over among the rocks at the upper part of the river, where the French had thought such an enterprise unlikely or impossible. A party of the combined army was thus enabled, on the following morning, after crossing the river, to turn the French fortifications, and to attack their flank and rear, while the rest of the army forced the passage of the river at different points. The French fought obstinately, but were speedily driven from all their positions, and compelled to retire to Pavia, leaving 6000 men on the field; while upwards of 5000 prisoners, including 4 generals, fell into the hands of the allies, together with 80 pieces of cannon.

359 And defeats him with great slaughter.

The advantage thus obtained over the French, in consequence of the address with which the Adda was crossed, is said to have gained for Suwarrow more estimation from his antagonists than they had originally been disposed to grant to any military officer coming from Russia, and who had never before had personal experience of the mode in which war is conducted in the south of Europe. But this is probably affectation. The French had surely no cause to despise Russian generals, since they could not but know that Laudohn was born in Russia, that he had his military education there, and that he had risen to a high rank in the army before he entered into the service of the Empress Queen Maria Theresa. Indeed it is evident, that while their orators were declaiming against Suwarrow and his Russians as merciless barbarians, they were secretly trembling at his prowess and resources, which they could not but remember had more than once saved the armies of the Prince of Cobourg in the Turkish war.

Moreau now established the wreck of the French army, amounting to about 12,000 men, upon the Po, between Alessandria and Valentia. On the 11th of May he compelled a body of Austrians to retire, though they had already passed the river, and took a great number of them prisoners. On the following day, 7000 Russians crossed the Po at Basignano, and advanced on Pecetto. Moreau immediately fell upon them with his army. They maintained a long and desperate conflict; but being at last thrown into confusion, and refusing to lay down their arms, about 2000 of them were drowned in recrossing the river, and the French, with difficulty, took a small number of them prisoners. But Suwarrow soon advanced, and terminated this active, but petty warfare, which was all that the French could now maintain. Moreau was under the necessity of retiring with his troops to occupy the Bochetta, and other passes which lead to the Genoese territory; and the combined army commenced vigorously, and at once, the siege of all the fortresses in the part of Italy which it now occupied. Peschiera, Mantua, Ferrara, Tortona, Alessandria, and the citadels of Turin and Milan, were all attacked. The French were driven from the Engadine by Bellegarde; Massena, closely pressed in Switzerland by the Archduke Charles, was compelled to retreat to the neighbourhood of Zurich, and almost all Piedmont had risen in insurrection against the French; so that in every quarter their affairs seemed desperate. Few or no reinforcements arrived from the interior, and their generals were left to act upon the defensive, and to detain the enemy at a distance from the frontiers of France as long as possible. One effort of offensive war only remained, and, after some delay, it was made with much vigour.

Macdonald

360 Macdonald and Moreau concert measures for attacking the allies.

Macdonald was still with a considerable French army in the southern parts of Italy, and occupied the territories of Rome and Naples. No attempt was made on the part of the combined powers to cut off his retreat; probably from the conviction that such an enterprise could not be accomplished with success in the mountainous countries of Tuscany and Genoa, through which it would be in his power to pass. Aware of this circumstance, he was in no haste to remove, though the combined army now occupied almost the whole territory between him and France. He gradually concentrated his forces, however, and drew near to the scene of action. His army amounted to 30,000 men; and he was ordered by the Directory to evacuate the new-born republics of Rome and Naples, and to form a junction, if possible, with the army of Moreau. The present situation of the allies, however, tempted Macdonald to hazard an action by himself. Marshal Suwarrow had extended his forces over Lombardy and part of Piedmont, in order to afford protection to the well disposed inhabitants of these countries; and Macdonald and Moreau had concerted between them a plan for dividing their antagonists, and vanquishing them, as the French generals had often vanquished their enemies in detail. It was only by Macdonald, however, that any important blow could be struck; but it was necessary that Moreau should draw upon himself a great part of the Austro-Russian forces, that the remainder might be more completely exposed to his colleague's attack. For this purpose he had recourse to a stratagem.

361 Junction of the French and Spanish fleets.

Towards the end of April, the French fleet, amounting to 16 ships of the line, had ventured out of Brest harbour. Ireland was supposed to be the place of its destination; and the British fleet was stationed in the situations most likely to prevent its arrival there. The French, however, intending to form a junction with the Spanish fleet, which was still blockaded in the port of Cadiz, sailed southward. When they approached Cadiz, a storm arose, which prevented any attempt on their part to enter the harbour, and any effort on the part of the British admiral, Lord Keith, to bring them to an engagement. On the 4th and 5th of May, therefore, they passed the Strait of Gibraltar, and steered for Toulon Lord Keith kept his station near Cadiz till the 9th of May, and then entered the Mediterranean in quest of the French fleet. The Spaniards immediately put to sea, and went into the Mediterranean also. The French fleet entered Toulon, and afterwards went out in quest of the Spanish fleet. They sailed towards Genoa, and afterwards to Carthagena, where they met their allies. The two fleets being now united once more, passed Gibraltar, and sailed round to Brest, where they arrived in safety, without being overtaken by the British.

Moreau, in the mean time, took advantage of the arrival of the French and Spanish squadrons in the vicinity of Genoa, to spread a report that they had brought him a powerful reinforcement of troops, in the hope of withdrawing from Macdonald the attention of Suwarrow. This last officer was himself at Turin His advanced troops possessed the passes of Susa, Pignerol, and the Col d'Assiette; while, at the lower extremity 362 of the vast track of country over which his army was scattered, General Hohenzollern was posted at Modena with a considerable force, and General Ott was at Reggio with 10 000 men. On the 12th of June, Macdonald began his operations. His advanced divisions attacked Hohenzollern at Modena on that day, defeated him, and took 2000 of his men prisoners. The French, at the same time, attacked General Ott; and, after obliging him to retreat, they entered Parma on the 14th of June. On the 17th, General Ott was again attacked, and compelled to retire upon Castel St Giovanni. But here the progress of Macdonald was arrested.

362 Partial successes of Macdonald.

Suwarrow had been informed of his approach and alarming successes; and with that presence of mind, and that promptitude of energy, which so strongly mark the whole of his conduct, he suddenly left Turin on the 15th of June, at the head of 20,000 men; and having marched seventeen leagues in eight-and-forty hours, came up with Macdonald's army on the banks of the Tidone. The Russian Generals Rosenberg and Foerster commanded the right and the centre; the left wing was commanded by the Austrian General Melas; the Russian General Prince Procration commanded the advanced guard, [illegible] the reserve. A desperate action [illegible] with equal obstinacy on both [illegible] three successive days. At len[illegible] to the standard of Suwarrow, [illegible] The French, driven on the 1st day [illegible] the Trebbia, were there ultimately defeated on the [illegible] after a carnage on both sides, such as some of the [illegible] officers in the army declared that they had never before seen. The Russians and [illegible] each others line, and were mutually [illegible] appeared in person wherever [illegible] troops most closely pressed [illegible] killed under him, and to have [illegible] on the 19th, running on foot from rank to rank, to urge the troops forward by his presence and example (H). With all these exertions of heroism, however, and greater have seldom been made, the issue of the contest continued doubtful, till the gallant Kray, in direct disobedience to the pernicious orders of the Aulic Council at Vienna, arrived at the head of a large detachment from the army besieging Mantua, and, on the 19th, decided the fate of the day.

The French fled during the night; and, on the morning of the 20th, Suwarrow pursued them with his army in two columns. It seldom happens that German troops can overtake the French in a march. The Russians now did so, however; and at Zena the rear guard of the French, being surrounded, laid down their arms. The

(H) We had this information from an officer of high rank, now residing in Weimar, who was present in the action; and who added, that the Cossacs, as soon as they saw their old commander in his *shirt*, rushed upon the enemy with an impetuosity which nothing could withstand. The story is by no means incredible; for Suwarrow, who despises costume, is known to have fought repeatedly in his shirt against the Turks; and he would be as hot on the Trebbia as ever he was on the Danube.

French Revolution, 1799.

The rest of the French army found safety in the passes of the Appennines and the Genoese territory, after having lost on this occasion, in killed, wounded, and prisoners, not less than 17,000 men.

Moreau, in the mean time, had attacked the Austrians under General Bellegarde in the vicinity of Alexandria. Though superior to him in numbers, they were completely beaten; but Suwarrow having returned with infinite rapidity after his victory over Macdonald, the temporary advantage gained by Moreau became of no importance. Suwarrow complained loudly of the conduct of the Aulic Council on this occasion; while they, in return, imputed their disaster under Bellegarde to his unskilful distribution of the whole troops, which had exposed an immense army to great danger from the enterprises of an handful of men. It is not our business to decide between them. The instructions of the Council to Kray not to co operate with the commander in chief of the combined army, seem to us in the highest degree absurd, if not treacherous; and we have heard a general officer, whose name, were we at liberty to give it, would do honour to these pages, say, that the distribution of the troops, of which that council complained, was the most masterly thing that has been done during the war. Be this as it may, a distrust and mutual misunderstanding thus commenced, or, at least, made its first open appearance, which gave good reason to suspect that little cordiality of co-operation would long exist between these allies. They continued, however, for some time to enjoy uninterrupted prosperity under the command of Suwarrow. The sieges of the [illegible] fortresses were very closely pressed. They [illegible] in succession; and the period appeared [illegible] when it would be in the power of the [illegible] enter the ancient territory of France.

364 Mutual complaints of Suwarrow and the Aulic Council.

If we turn our eyes to a different quarter, we shall find the French as much humbled at this time in Palestine by British valour, as they were in Italy by the united armies of Russia and Austria. The hero of [illegible] the conqueror of Italy, the boasted legislator of [illegible], who having defeated the Mamalukes, taken possession of Alexandria and Cairo, and professed himself a Mahometan in Egypt, led an army into Palestine with the avowed purpose, it has been said, to take possession of Jerusalem, and by rebuilding the temple, and restoring the Jews, to give the lie to the prophecies of the Divine founder of the Christian religion. At the head of a chosen band, exceeding 12,000 in number, and possessed of a staff eminent for military skill and experience, he arrived at the small town of Acre, situated on the sea-coast, 28 miles south of Tyre, and 37 north of Jerusalem. To this town, which was wretchedly fortified, and defended only by a small garrison of Musselmans, he laid siege in form; and the governor would have surrendered unconditionally, had he not been, we say not *persuaded*, but *decoyed*, by an English *naval* officer, to make a vigorous resistance. We need not add, that the naval officer was Sir Sidney Smith, or that the besieging general was Bonaparte.

365 Bonaparte's unsuccessful attack of Acre.

The command of the garrison being entrusted to Sir Sidney Smith, who was not to be bribed by French gold, or corrupted by French philosophy, the hero who, by the aid of these allies, had so quickly routed armies, and conquered states in Italy, was detained before the town of Acre *fixty-nine* days; though the number of the allies who defended that town exceeded not 2000 men! Foiled in *eleven* different attempts to carry it by assault, one of which was made during the truce which he himself had solicited to bury the dead, he was ultimately obliged to retreat, leaving eight of his generals, eighty-five of his officers, and *one half* of his army behind him. The superiority of the British over the Corsican hero was, during this siege, more fully displayed in conduct than even in courage. The true magnanimity evinced by the former; his temperate replies to the audacious calumnies and atrocious falsehoods of his adversary; and the moderation and humanity which characterised his dispatches, and invariably marked his behaviour to those whom the fortune of war subjected to his power—give additional lustre to the brilliant victory which his valour, his energy, and his perseverance, so essentially contributed to secure.

But while we pay a tribute of justice to the merits of our gallant countryman, we must not omit to notice the high deserts of the brave, the loyal, the virtuous Philipeaux, his gallant comrade, the partner of his toils, and the partaker of his glory. The skill of this French officer as an engineer was most successfully displayed in the defence of Acre; and, indeed, his exertions on that memorable occasion so far surpassed his strength, that he actually perished through fatigue.

The defeat of Bonaparte at Acre, which effectually stopped his destructive career, will be considered as important indeed, when it is known that his arts of intrigue had so far succeeded as to prevail on the numerous tribe of the Druses to join his standard with *fixty thousand* men immediately after the reduction of that town. Had this junction been effected, it was intended to proceed to Constantinople, and, after plundering the city, to lay it in ashes! It is scarcely possible to calculate the dreadful consequences of such an event on the political state of Europe. If services are to be estimated in proportion to their effects, we know of none, during the present war, fertile as it has been in brilliant atchievements, that deserves a higher reward than the defeat of Bonaparte at Acre.

His vast projects, had he succeeded.

During these reverses abroad, France had begun to suffer much internal agitation, and the Directory found itself in a very difficult situation. The elections, as usual, were unfavourable to them; and amidst the contempt with which they now began to be regarded, it was no longer possible to secure a majority in the Councils, by unconstitutionally annulling the elections of their political opponents. They demanded money, and were answered by reproaches, on account of their profusion, and the rapacity of their agents. The royalists in the south and the west began to form insurrections. They were subdued with much difficulty, on account of the absence of the troops. The people had totally lost that enthusiasm which, in the earlier periods of the revolution, induced them to submit to so many evils, and to make the most violent efforts without murmuring. They beheld the renewal of the war with regret, and were unwilling to assist by their exertions to restore power and splendour to the faction which had trampled upon their freedom.

Amidst all these difficulties, an event occurred which, for a time, gave the Directory the hope of being once more able to rouse the dormant energies of their countrymen. After the defeat of Jourdan, a detachment from

French Revolution, 1799.

from the army of the Archduke Charles had occupied Rastadt, where the Congress still sat. On the 28th of April an order was sent by an Imperial officer to the French ministers, requiring them to quit Rastadt in 24 hours. They demanded a passport from Colonel Barbascy, who had sent the order; but this he could not grant, none having that power but the commander in chief.

367 Assassination of the French envoy

They declared themselves determined to depart without delay, although the evening approached. They were detained about an hour at the gate of the town, in consequence of general orders which had been received by the military to suffer none to pass. In consequence of an explanation, however, and of the interposition of superior officers, they were allowed to depart. The three ministers, Bonnier, Roberjot, and Jean Debry, were in carriages. The wife of Roberjot, and the wife and daughters of Jean Debry, were along with them; and they were attended by the ministers of the Cisalpine republic. When they had advanced to a very short distance from Rastadt, they were met by about 50 hussars of the regiment of Szeckler, who made the carriages to halt, and advancing to the first of them, containing Jean Debry, demanded his name. He told them his name, and added that he was a French minister returning to France On receiving this answer, they immediately tore him from his carriage, wounded him in several places with their sabres, and cast him into a ditch, on the supposition that he was killed. They treated in the same manner the two other ambassadors, Bonnier and Roberjot, whom they murdered upon the spot. They offered no personal violence, however, to the rest of the company, who were allowed to return to Rastadt; but they robbed the carriages of whatever effects they contained; and the papers of the ambassadors were conveyed to the Austrian commander. After the departure of the soldiers, and the return of the carriages to Rastadt, Jean Debry wandered about the woods all night, and returned also to Rastadt on the following day. He claimed the papers belonging to the legation from the Austrian commander, but they were refused to be restored.

During the whole of the long period that the Congress had sat, Rastadt and its vicinity had been occupied by French troops, and it was only a few days since the Austrians had obtained possession of it. This event therefore cast, at least, a severe reproach upon the discipline of the Austrian army. It did more; it made every honest man regret, that troops, engaged in the support of a good cause, should think to promote that cause by the murder even of the greatest villains. The Archduke Charles made haste to disclaim all knowledge of it in a letter to Massena; but the French Directory, regarding it as a fortunate occurrence, from its tendency to rouse the resentment of the nation, addressed to the two Councils, on the 5th of May, a message, in which they ascribed it to a deliberate purpose on the part of the Austrian government to insult France by the assassination of her ambassadors. They thus converted the private act of a few desperate individuals into a measure of public policy; as if the death of those wretched miscreants could have been of consequence to the enemies of the *great* nation. The unpopularity of the Directory, however, and the obvious inutility of so gross a crime, prevented this accusation from obtaining much credit, or producing great effects upon the people. In

368 Turned by the Directory to its own advantage.

a private letter which a friend of our's received at that period from the Continent, he was assured that the murder of the envoys "*fait plus de bruit que de sensation;*" and that the general opinion was, that the Directory itself knew more of the authors of that crime than the Archduke or the Austrian government.

369 Dissensions in France.

Upon the introduction of the new third of this year into the Councils, a violent opposition to the Directory commenced. Sieyes, who was ambassador at Berlin, and who had enjoyed, during the whole progress of the revolution, a very considerable influence over all the parties that had successively enjoyed the supreme authority, was elected into the Directory. At the first establishment of the constitution he had refused to occupy this station, and it excited much surprise when he readily accepted the office in the present calamitous state of the Republic. His admission into the Directory, however, did not reconcile the public or the two Councils to that body. A violent contest for power betwixt the Moderate and the Jacobin parties seemed to approach; but they soon came to a compromise. Treilhard was removed from the Directory, under the pretence that he had held an office in the state within less than a year previous to his nomination. Merlin and Reveillere were compelled to resign, to avoid an impeachment with which they were threatened; but Barras still contrived to retain his station. Moulins, Gohier, and Ducos, men little known, and by no means leaders of the contending parties, were appointed Directors. The power was understood to be divided, and that neither party greatly [illegible]. An attempt was made to revive public spirit, by [illegible] the institution of clubs, which [illegible] the Directory. The violent Jacobins [illegible] take advantage of this licence. The[illegible] ancient style, their proposals for violent measures, and their practice of denouncing the members and the measures of government. But the Directory becoming alarmed by their intemperance, obtained leave from the Councils to suppress their meetings, before they were able to interest the public in their [illegible].

Considerable efforts were now made by the French government to recruit their armies; but the deranged state of the finances, which the votes of the Councils could not immediately remedy, prevented the possibility of their gaining a superiority during the present campaign. The difficulty was also increased by the necessity of resisting immense armies in different quarters at the same time, France being assailed at once on the side of Holland, Switzerland, and Italy. Such, however, were the exertions of the Directory, that they seemed not destitute of the hope of being able speedily to assume, on the frontier, a formidable, and even menacing posture. In the beginning of August, their Italian army amounted to 45,000 men. The different bodies of troops of which it consisted had been drawn together, and concentrated nearly in the same positions which Bonaparte had occupied before his battles of Montenotte and Millesimo. The command of the whole was given to Joubert, a young man, who had been much distinguished under Bonaparte; and who, in the style of gasconade employed by that general, assured his government of victory, declaring, that he and Suwarrow should not both survive the first battle. In this boasting declaration he seems to have been in earnest;

371 Joubert assumes the command in Italy.

French Revolution, 1799.

earneft; for, on taking the command, he prevailed with Moreau to remain in the army as a volunteer till the firft battle fhould be fought. The allies had now taken Turin, Aleffandria, Milan, Pefchiera, and Ferrara, with a rapidity which would lead one to fuppofe that fome new mode had been invented of materially abrid-

372 Succeffes of the allies.

ging the duration of fieges. The ftrong citadel of Turin opened its gates, to the aftonifhment of Europe, after a bombardment of only *three days;* the citadel of Aleffandria furrendered to the Auftrian General Bellegarde, on the 22d of July, after a fiege of *feven days;* and the ftill more important fortrefs of Mantua furrendered to the brave General Kray, on the 29th of the fame month, after a fiege of only *fourteen days.* The garrifon of Aleffandria amounted to 2400 men; that of Mantua to 13,000. The former were detained prifoners of war, and the latter were allowed to return to France on their *parole;* a parole which the commanders of the allied armies could not reafonably expect to be kept. This has given rife to a fufpicion, that the fortrefs was voluntarily furrendered to the Auftrians, in order that the Directory might recruit its armies with the garrifon.

The allies next began to befiege Tortona, and Joubert refolved to attempt its relief. He hoped to accomplifh this object, and to gain fome advantage over their army, before General Kray could arrive to the affiftance of Suwarrow with the troops that had been occupied in the fiege of Mantua. On the 13th of Auguft, the French drove in the whole of the Auftrian [illegible] poffeffion of Novi. Here they encam[illegible] fteep, but not high, ridge of hills, [illegible] Novi, their right towards Sera[illegible] towards Bafaluzzo. On the 14th [illegible] quiet; and on the 15th they were at[illegible] by Suwarrow, whofe army was now reinforced by the arrival of General Kray from Mantua. The [illegible] army was commanded by Kray, [illegible] centre was occupied by the [illegible] (Procration) and [illegible] The attack began at 5 o'clock in the morning, and was continued during many hours. Soon after the commencement of the battle, while the French commander in chief, Joubert, was urging his troops forward to a charge with the bayonet, he received a mufquet fhot in his body, and, falling from his horfe, immediately expired. Moreau inftantly refumed the command. After an obftinate conteft, the allied army gave way, and was compelled to fall back in all quarters. The attack, however, was repeatedly renewed, and much blood was fhed. From the obftinate manner in which they fought, the Ruffians, in particular, fuffered very feverely. They made three unfuccefsful efforts againft the centre of the French army, and on each occafion thofe immediately engaged were rather deftroyed than repulfed. The laft attack along the whole line was made at three in the afternoon. The French remained unbroken; and the day muft have terminated in the defeat of the allies, had not General Melas fucceeded in turning the right flank of the French line. Their right wing was thus thrown into confufion. Melas purfued his advantage till he obtained poffeffion of Novi, and the whole French army made a rapid retreat under the direction of Moreau.

According to the accounts given by the Auftrians, the French loft in this battle 4000 killed and an equal number taken prifoners. They acknowledged their own lofs in killed to be equal to that of the French, but the lofs fuftained by the Ruffians was never publifhed. The general refult of the battle was the total ruin of the French affairs in this quarter. The allies retained their decided fuperiority; and there was no enterprife which, on the prefent theatre of the war, they might not have ventured to undertake. The French renounced all hope of defending Genoa, and prepared to evacuate that city and its territory. The Directory expected an immediate invafion of the fouth of France, and addreffed a proclamation to the people, urging them to act with firmnefs and energy amidft the calamities with which the country was now menaced. 374

Unaccountable conduct of the allies.

But thefe apprehenfions were unneceffary. The court of Vienna had other objects in view that were lefs dangerous to their enemy. They neither invaded Genoa nor France, but quietly proceeded in the fiege of Tortona. The vanquifhed army was furprifed to find itfelf unmolefted after fuch a defeat; and in a few days ventured to fend back parties to inveftigate the movements of the allies. The new commander Championnet, who had fucceeded Joubert, found to his no fmall aftonifhment that they had rather retreated than advanced; and he immediately occupied the fame pofitions which his army had held before the battle of Novi.

Inftead of purfuing the advantages they had gained in Italy, the Aulic council, or council of war at Vienna, now perfuaded Suwarrow to leave that country with his Ruffians, and to fet out for Switzerland to drive the French from thence. In the early part of the campaign, the Archduke Charles had fucceeded, after various attacks, in driving the French from the eaftern part of Switzerland beyond Zurich, of which laft city he retained poffeffion. The Directory, however, had fent their new levies chiefly towards this quarter; fo that in the middle of the month of Auguft Maffena's army amounted to 70,000 men. The Archduke was now fo far from being able to purfue the advantages he had gained, that of late the French had returned the offenfive, and threatened to endanger his pofition. Their right wing under Lecourbe had even fucceeded in taking poffeffion of Mount St Gothard, which is the great pafs that leads from the centre and eaftern part of Switzerland into Italy. The cabinet of Vienna probably wifhed to throw the fevereft duties of the war 375

Suwarrow leaves Italy, and marches to Switzerland.

upon their northern affociates. The veteran Suwarrow had never, during his long military career, fuffered a fingle defeat. His prefumption of fuccefs was therefore high; and he perhaps felt himfelf not a little flattered by the requeft to undertake an enterprife in which the Auftrians had failed, though led by their moft fortunate commander. It is indeed certain that he confidered himfelf as called out of Italy too foon. Though confident of being properly fupported, he agreed to proceed with his troops from Piedmont to Switzerland, where another Ruffian army had lately arrived. Delays, however, were thrown in his way. Tortona did not fall quite fo foon as was expected; and when he was ready to march, the Auftrian commander in Italy refufed to fupply him with mules for the tranfport of his baggage. Unable to reply to the indignant expoftulations of the Ruffian hero, this man defcended to a pitiful falfehood, by affuring him that he would find a

 fufficient

French Revolution, 1799.

sufficient number of mules at Bellinzone, where, when he arrived, not one was to be had. He had now no other resource but to dismount the cavalry, and employ their horses to drag along the baggage. Under all these difficulties, he arrived, by forced marches, on the confines of Switzerland, on the day appointed by him and the Archduke; but the Austrian cabinet had, in the mean time, taken a step which made all his exertions useless.

376 Is deserted if not betrayed, by the Austrians.

Thinking it degrading to a Prince of the Imperial house, who had so long held the highest military rank, to serve under the Russian General, and not having the confidence to require the most experienced leader in Europe to receive the orders of a man so young as the Archduke, they sent that prince with his army to attack the French, who, in a small body, had entered into Swabia. He began accordingly to draw off his troops in the beginning of September, before Suwarrow was in readiness to leave Italy. The number which he took with him has been differently estimated, the lowest computation stating it at 48,000, and the highest at 60,000. The former is the most probable; since it is well known that 20,000 would have been fully adequate to the purpose for which he marched. The army which he left behind him is more perfectly ascertained: it consisted of 21,000 Russians, 18,900 Austrians, Bavarians, and other auxiliaries, forming a total of 39,900 men.

Upon what principle of military tactics the Aulic council could suppose that a skilful and intrepid commander like Massena, with a force nearly double that of the allies, would remain in a state of inactivity, it is not easy to conceive. He perceived at once the advantage which might be derived from this unaccountable movement of the Archduke. The French troops in Swabia were therefore ordered to advance rapidly, and to threaten the rear of the Archduke's army. As the repulse of these troops, and the invasion of France towards Alsace, formed a part of the Austrian commander's plan of operations, he marched against them with his army. The French made as much resistance as the smallness of their force would permit. The Archduke, however, gradually drove them towards the Rhine. The better to carry on their plan of deception, they made a serious stand in the neighbourhood of Manheim, and were defeated with the loss of 1800 men. The Austrians entered Manheim, and seemed ready to cross the Rhine in this quarter.

All this while Switzerland was left completely exposed to the enterprises of Massena. General Hotze, with the Austrians, occupied the right wing of the allied army there. The newly arrived Russian army was stationed in the centre at Zurich, under the command of General Korsakof; and the left, consisting chiefly of Bavarians and other troops of the empire, was commanded by Nauendorf. Massena remained quiet till he learned that the Archduke had entered Manheim, and that Suwarrow, having taken Tortona, was on his march towards Switzerland by Mount St Gothard.

377 The allies defeated in Switzerland.

This last position was defended by Lecourbe; and Massena resolved, in the mean time, to anticipate the arrival of Suwarrow. On the 24th of September, having drawn the attention of the Russians to another quarter by a false attack, he suddenly crossed the Limmat, a river which divided the two armies near the convent of Farr, which is three leagues distant from Zurich. A part of the French troops engaged the Austrians, while the greater part of the army marched against the Russians at Zurich. The Austrian General Hotze was killed in the commencement of the action: General Petrarch, who succeeded him in the command, contrived to avoid a total rout, and retired during the night with the loss of about 4000 men. The contest with the Russians was singularly obstinate. In a mountainous country, to which they were strangers, and contending against the most skilful military leaders that the south of Europe had been able to produce, they laboured under every disadvantage. They could not be put to flight, however; and even when different divisions of them were surrounded, they refused to lay down their arms, and were slaughtered upon the spot. By the retreat of the Austrians on the evening of the 25th, they found themselves on the 26th nearly surrounded in Zurich. They now began to retreat also; and we are only surprised at the ability of the Russian General in effecting his retreat in such good order, and with such little loss; for if the official accounts deserve credit, his loss in killed, wounded, and taken, did not exceed 3000 men. He was obliged, however, to abandon his baggage and cannon to the enemy.

378 Suwarrow's march.

During these operations, Suwarrow was advancing on the side of Italy with an army rated, in some accounts, at 18,000, in others at only 15,000; and forcing the French from [illegible] ng positions on Mount St Gothard, [illegible] very day on which Massena made his general attack, into the valley of Urseren; and driving Lecourbe before him, with considerable slaughter, advanced as far as [illegible] penetrated on the next day into the [illegible] and took 1000 of the French prisoners; while the Russian General Rosemberg was equally successful in the canton of Schwitz, where General Auffenberg had effected a junction with him; and General Linken defeated and took another corps of French, consisting of 1300 men.

379 His admirable conduct.

Massena, however, now turned upon the Field-marshal with the greater part of his army; and, by hemming him in on all sides, expected to have made him, and the Grand Duke Constantine, prisoners. Suwarrow, however, defended himself against every attack with unexampled vigour and address. A single pass among the mountains was all that remained unoccupied by the French. He discovered this circumstance, and escaped, though closely pursued. He lost his cannon, baggage, and provisions, among the dreadful mountains and precipices with which that country abounds. He made his way, however, eastward through the Grison country, and at length arrived at Coire with about 6000 men in great distress.

Nothing could exceed the indignation of this old warrior when he discovered the manner in which affairs had been conducted, the hazardous state in which the Russians had been abandoned by the Archduke, and the consequent ruin which they had encountered. He considered himself and his countrymen as treacherously exposed to destruction; he loudly complained of the Commander of the allied forces in Switzerland; publicly taxed the council of Vienna with selfishness and injustice; and refused all farther co-operation with the Austrian army. He sent an account of the whole trans-

380 His indignation at the court of Vienna.

French Revolution, 1799.

French Revolution. 1799.

action to St Petersburgh in a letter, of which the composition would do honour to the finest writer of the age, and withdrew with his troops to the neighbourhood of Augsburg to wait for farther orders.

380 Invasion of Holland.

In the mean time, Great Britain prepared to invade Holland with an army of 40,000 men, consisting of British troops and Russian auxiliaries. The first division, under General Sir Ralph Abercromby, sailed in the month of August, under the protection of a fleet commanded by Admiral Lord Duncan. Bad weather prevented a landing from being attempted till the 27th. On the morning of that day the troops landed without opposition upon the shore of Helder Point in north Holland, at the entrance to the Zuyder Sea. They had not been expected in this quarter, and the troops in the neighbourhood were consequently few. The British, however, had no sooner begun to move forward, than they were attacked by a considerable body of infantry, cavalry, and artillery, who had been hastily assembled from the nearest towns. The Dutch troops maintained the contest with much obstinacy; but they were gradually fatigued by the steady opposition they encountered, and retired to the distance of two leagues. In the night they evacuated the fort of Helder, of which the British took possession on the morning of the 28th. A detachment from the British fleet, commanded by Vice Admiral Mitchell, now entered the Zuyder Sea by the strait of the Texel, to attack the Dutch fleet

381 Capture of the Dutch fleet.

under Admiral Story. This last officer, instead of retiring for safety to any of the ports, or to the shallow water with which that sea abounds, surrendered the [illegible] 30th of August without firing a [illegible] that his seamen were mutinous, [illegible]

Had the expedition terminated here, it might have [illegible] regarded as extremely fortunate, and as establishing the power of the [illegible] navy without a rival. But it was [illegible] his first success by an effort on land to restore the [illegible] of the Stadtholder, and the ancient government of the United Provinces. Many circumstances were hostile to this enterprise. The whole army had not been sent at once from Britain. As no more than the first division had arrived, the troops could only rest upon the ground they had gained till reinforcements should be sent. The terror arising from the first appearance of an invading army was thus allowed to pass away, the enemies of the present Dutch government were discouraged, and leisure was afforded to adopt effectual measures of defence. The place where the landing was effected was well chosen for an attack upon the Dutch fleet; but for an invasion, with a view to the restoration of the Stadtholder, it was the worst that could have been selected. North Holland, at the extremity of which it was made, is a narrow peninsula, everywhere intersected by canals and ditches, of about 40 miles in length. Here the invaders might be detained, and even successfully resisted, by a force greatly inferior to their own. This also is the quarter of the country the most unfavourable to the cause of the Stadtholder. In Zealand, where his estates are situated, and in Rotterdam, which is full of Scotchmen and of families of Scottish extraction, his friends are numerous and powerful; but in Amsterdam, and in North Holland, which is under its influence, his enemies abound, and the resistance to his power has been very great during every period of the Dutch history. When to all this it is added, that the rainy season was approaching, and that a winter campaign in Holland is almost impossible, it will not appear surprising that this expedition was attended with little ultimate success. It is said that, amidst the pressure of the many difficulties which surrounded them, the French Directory hesitated much about undertaking the defence of Holland; but the place, and the time of landing the invading army, at once brought them to a determination. General Brune was sent thither, with whatever troops could be hastily collected, to support the Dutch General Daendels.

382 Progress of the invaders.

General Abercromby, in the mean time, remained upon the defensive at Schager Brug, waiting for reinforcements. His inactivity encouraged the enemy on the 10th of September to venture an attack upon his position. They advanced in three columns, two of which consisted of Dutch and one of French troops. They were repulsed, however, in all quarters, and retired to Alkmaer. On the 13th the Duke of York arrived with additional troops, and assumed the chief command. The Russian auxiliaries having also arrived, offensive operations were immediately resolved upon. On the 19th the army advanced. General Abercromby commanded the left, which proceeded along the shore of the Zuyder Sea against Hoorne. The centre columns were commanded by Generals Dundas and Pultney; and the right wing, consisting of Russians, was commanded by their own General D'Herman. In consequence of some strange misunderstanding, the Russians advanced to the attack soon after three o'clock in the morning, which was some hours previous to the movement of the rest of the army. They were successful in their first efforts, and obtained possession of the village of Bergen; but pressing eagerly forward, and being unsupported by the other columns, they were nearly surrounded. Their commander was taken prisoner; and though the British came in time to protect their retreat, they lost at least 3000 men. This failure on the right obliged the British Commander in Chief to recal his troops from the whole advanced positions they had gained, though General Abercromby had actually taken Hoorne with its garrison, and although General Pultney's column had carried by assault the principal position of the Dutch army called *Greb Copp l.*

The severity of the weather prevented another attack till the 2d of October, when, after an engagement that lasted from six in the morning till the same hour in the evening, the British army succeeded in driving the united Dutch and French troops from Alkmaer and the villages in its neighbourhood. The contest was chiefly conducted among the sand hills in the vicinity of the ocean; and the battle was maintained with such obstinacy, that the fatigue of the troops, together with the difficult nature of the country, prevented the British from gaining any great advantage in the pursuit. The retreating army immediately occupied a new position between Baverwyck and Wyck op zee. The Duke of York once more attacked them on the 6th; and after an obstinate and bloody engagement, which was maintained till night, he remained in possession of the field

383 Stopped by the enemy and the inclemency of the weather.

of battle. But this was the last success of the invaders. Finding himself unable to make farther progress, in consequence of the increasing numbers of the enemy, the impracticable nature of the country, and the badness

French Revolution. 1799.

of the weather, which, during the whole of this year, was unusually severe, the Duke of York retired to Schager Brug, and there waited for orders from England to return home. He was, in the mean time, closely pressed by the United Dutch and French forces, so that his embarkation must have been attended with much hazard. He therefore entered into a convention with the French and Dutch generals; by which it was agreed, that they should no farther molest him in his retreat, and that, in return, he should not injure the country by breaking down any of the dykes which protect it against the sea, and that Great Britain should restore to France and Holland 8000 prisoners of war, taken previous to the present campaign.

In consequence of these events, the affairs of France now began to assume a less unfavourable aspect. They were indeed driven to the extremities of Italy, Championet was defeated in every effort which he there made against the Austrians during the rest of the year, and Ancona, which was the last place of any strength possessed by the French, also surrendered on the 13th of November to General Frolich; but they retained the Genoese territory, and Switzerland and Holland continued under their power. The new coalition against them seemed once more ready to dissolve. From the commencement of the French Revolution, a spirit of selfishness had mingled with all the efforts made by the continental powers of Europe against it, and had rendered them fruitless. To prevent the aggrandisement of Austria, Prussia had early withdrawn, and still stood aloof. Spain and Holland were retained under the influence of France by the efforts of her arms, and by the universal diffusion of her wild principles among the people. Even the British cabinet, which of all the European powers has remained most true to the original purpose of the war, sometimes forgot that object. Thus, when invading Holland, the Dutch were informed, by a proclamation, that their ancient government was to be restored; but no offer was made to restore their distant possessions. Of all the coalesced powers, however, Austria pursued her separate interests with the least disguise. With much facility she relinquished the Netherlands, and suffered the principal bulwarks of Germany, Mentz, and Ehrenbreitstein, to fall into the hands of the French, upon obtaining in exchange the Venetian territories, which Bonaparte had conquered, and thought himself authorised to sell. During the present campaign, the whole conquests made by the united efforts of the Austrian and Russian forces were seized by Austria in her own name, and none of the Princes of Italy obtained leave to resume the government of their own territories. This conduct on the part of the allies gave every advantage to the French. They broke off the negociations at Lisle, under the pretence of defending the Dutch and Spanish settlements which the British government refused to relinquish. They found it easy to alarm the King of Prussia, by displaying the unbounded ambition of the house of Austria; and the Emperor of Russia, having publicly declared to the members of the German empire, that the purpose for which he had taken up arms was not to dismember France, but to restore peace to Europe, became jealous of the Court of Vienna, when he saw it pursue a conduct so very different. This jealousy was encreased by the misfortunes of the Russian troops; and all circumstances seemed now to promise that the new coalition would speedily be deserted by its northern auxiliary.

254 Coalition against France ready to be dissolved.

While affairs were in this state, an event occurred which exhibited the French Revolution under a new aspect. When Bonaparte found himself compelled to retreat, baffled and disgraced, from the ruins of Acre, he learned that a Turkish army was ready to invade Egypt by sea. He returned, therefore, with his usual celerity, by way of Suez, across the desart of Arabia Petrea, which divides Syria from that country, and was in the neighbourhood of the Pyramids on the 11th of July, when an army of 18,000 Turks landed from 100 ships at Aboukir. They took this fort by assault, and gave no quarter to the French garrison of 500 men that it contained. On the 15th, Bonaparte began to march down the country against them. On the 25th he came in sight of them, at six o'clock in the morning.

255 Bonaparte vanquishes the Turks in Egypt

It is not wonderful that those barbarians afforded him an advantage which had so often been presented by the armies of Austria. They had divided their force into two parts, which were encamped on the opposite sides of a beautiful plain. He had now formed a considerable body of cavalry, by obtaining for his men fleet horses from Arabia. These advanced rapidly into the centre of the Turkish army, and cut off the communication between [illegible] parts. His infantry then attacked the [illegible] the Turks. [illegible] ed to fly to [illegible] the sea. [illegible] tacked. It [illegible] soon also put to flight. Some [illegible] sea, and perished in attempting to [illegible] their fleet; the rest took [illegible] ge in [illegible] kir. The [illegible] reached France towards the end of September, and revived [illegible] naparte's [illegible] ictories, contrasted with [illegible] the Republican armies [illegible] 10th of October [illegible] the Directory, [illegible] count of the cap[illegible] whole remains of [illegible] army. On the 14th of the same month a message from the [illegible] announced, to the astonishment of all men, that [illegible] aparte, along with his principal officers, had just arrived in France, and that they left the army in Egypt in a prosperous state. This last part of the message was soon afterwards proved, by the intercepted letters of Kleber, and the other generals left behind, to be a scandalous falsehood. In one of these letters, Poussielgue says, "Every victory carries off some of our best troops, and their loss cannot be repaired. A defeat would annihilate us all; and however brave the army may be, it cannot long avert that fatal event."

[illegible] Arrives with his principal officers in France,

Bonaparte, however, was received at Paris with distinction, though nobody could tell why he had deserted his army and come thither. The parties in the government were equally balanced; and both the Jacobins, and what were called the *Moderates*, solicited his assistance. The Jacobins still possessed a majority in the Council of Five Hundred; but in the other Council their antagonists were superior. The Director Sieyes was understood to be of the party of the Moderates; and the Jacobins had of late unsuccessfully attempted

French Revolution, 1799.

to remove him from his office, under the pretence that the interval appointed by the constitution had not elapsed between his going out of the Council of Five Hundred and his election to the office of director. Neither party was satisfied with the existing authorities; but none of the usual indications of approaching hostilities appeared. The Jacobins were far from suspecting that Sieyes had a plot ripe for execution, which was to overwhelm them in an instant. They were even in some measure laid asleep by an artful scene of festivity, in which the whole members of the Councils were induced to engage, on the 6th of November, under pretence of doing honour to the arrival of Bonaparte. On the morning of the 9th, one of the committees of the Council of Ancients, called the committee of Inspectors of the Hall, presented a report; in which they asserted, that the country was in danger, and proposed to adjourn the sitting of the legislature to St Cloud, a village about six miles from Paris. We have already mentioned, that the constitution entrusted to the Council of Ancients the power of fixing the residence of the legislative bodies, and that this Council could in no other case assume the initiative, or propose any law; their powers of legislation being otherwise limited to the unconditional approbation or disapprobation of the decrees passed by the Council of Five Hundred. The Council of Ancients now suddenly decreed, that both Councils should meet next day at St Cloud. As the Council of Five Hundred had no constitutional right to dispute the [illegible] party in [illegible] silently [illegible] the 10th of [illegible] Hundred exhibited a scene of [illegible] received a letter from Legarde, [illegible] Directory, stating, that four of its [illegible] resignation of their offices, and that [illegible] in custody by order of General [illegible] of their [illegible] the Coun[illegible], attended [illegible]. He [illegible] brother Lucien Bonaparte [illegible] president. Great confusion ensued; he was called a Cromwell, a Cæsar, an usurper. The members began to press upon him, and his countryman Arena attempted to stab him with a dagger. He was rescued by his military escort. Lucien Bonaparte then left the chair, and cast aside the badge of office which he wore as a member of the Council. The confusion did not diminish; but in a short time a party of armed men rushed into the hall, and carried off Lucien Bonaparte. A tumultuous debate now began; in which it was proposed that Bonaparte should be declared an outlaw. The debate was soon terminated, however. The doors of the hall were once more burst open. Military music was heard; and a body of troops proceeding into the hall in full array, the members were compelled to disperse. The Council of Ancients, in the mean time, setting aside the constitution, passed a variety of decrees. They abolished the Directory, and appointed in its stead an Executive Commission; to consist of Bonaparte, Sieyes, and Roger Ducos, under the appellation of Consuls. They adjourned the sittings of the legislative bodies till the 20th of February, and appointed two committees, consisting of twenty-one members, selected from each of the two councils, to act as legislators in the mean time. They also expelled a great number of members from their seats in the councils.

French Revolution.

Most of the members of the Council of Five Hundred returned to Paris, after having been driven from their hall by the military; but a part of them remained at St Cloud, and, on the evening of the same day, confirmed all the decrees of the Council of Ancients. The new government entered upon its functions at Paris on the following day. That city remained tranquil, and the public funds even rose upon the occasion. On the 17th of November the consuls decreed the transportation of a great number of the leading Jacobins and zealous republicans to Guiana, and ordered many others to be imprisoned; but these decrees were speedily recalled, and affairs went on as quietly as if nothing unusual had occurred.

388 [illegible]tions of Tippoo Sultan in India.

While Bonaparte was thus obtaining boundless personal aggrandisement in Europe, the African expedition in which he had been engaged was utterly unsuccessful in all its objects. The circumstances which led to it, so far as concerned foreign nations, now came to light, and were shortly these: Tippoo Sultan, the son and successor of the celebrated Hyder Ally, and sovereign of the Mysore country, which forms a part of the peninsula of India, had been compelled to conclude a treaty of peace in the year 1792 with the British governor general, Lord Cornwallis, under the walls of Seringapatam his capital. By this treaty he resigned to the invaders a part of his territory, and agreed to pay a large sum of money. He was, moreover, under the humiliating necessity of consenting that two of his sons should be delivered as hostages, to remain with the British till the pecuniary payments could be completed.

A war thus concluded could not become the foundation of much cordial amity between the parties. Tippoo had inherited from his father a deep sentiment of hostility against the growing power of Britain in India. Though he submitted on the occasion now mentioned to the necessity of his circumstances, yet he only waited a more fortunate opportunity to endeavour to recover what he had lost; and even, if possible, to accomplish the favourite object of all his enterprises, the complete expulsion of the British from India. At a former period, almost the whole of the native princes of this vast continent had entered into a combination against the power of Britain; but their designs had been defeated by the talents and exertions of Warren Hastings, Esq; The ascendency of the British government in this quarter was now so great, that no such combination could again be formed, and Tippoo felt that its power could only be shaken by the aid of an European army. France was the only country from which he could hope to obtain an adequate force. By the events of the revolution, however, and by the pressure of the war at home, the rulers of France had been prevented from attending to distant views and interests. Their settlements in India had been seized by the British, and they had ceased to retain any possessions beyond the Cape of Good Hope, excepting the islands of Mauritius and Bourbon. In the year 1797, Tippoo resolved to endeavour to renew his intercourse with the French by means of these islands. One Repaud, who had once been a lieutenant in the French navy, and had resided for some time at Seringapatam,

389 He renews his intercourse with the French.

French Revolution, 1799.

gapatam, had misled Tippoo into a belief that the French had a great force at the Mauritius, which could immediately be sent to his aid in case of a war. He therefore fitted out a ship, of which he gave the command to Ripaud, and sent two persons in it as his ministers, with powers to negociate with the French leaders at the Mauritius. But, at the same time, to avoid exciting the suspicions of the British government in his neighbourhood, he directed his messengers to assume the character of merchants, to act in that capacity in public, and to conduct their political negociations with secrecy. They arrived at the Mauritius towards the close of the year 1797, and opened their proposals to Malartic the governor, for an alliance between Tippoo and the French nation, with the view of obtaining the aid of an European army. They were received with great joy, and vessels were instantly dispatched to France to communicate their proposals to the Directory.

In the mean time, Malartic the governor of the Mauritius, from folly, from treachery, or from a desire to involve Tippoo, at all hazards, in a quarrel with the British, took a step which ultimately was in a great measure the means of defeating the plans, and accomplishing the ruin of that prince. On the 30th of January 1798, he published and distributed a proclamation, in which he recited the whole private proposals of Tippoo, and invited all French citizens to enlist in his service. Copies of this proclamation were speedily conveyed by different vessels, touching at the Mauritius, to the continent of India, to Britain, and to all quarters of the world. Accordingly, as early as the 18th of June 1798, the secret committee of the Court of Directors of the East India Company in London wrote to their governor general in India, requiring him, in consequence of this proclamation, to watch the conduct of Tippoo, and even to engage in hostilities, if the measure should appear necessary. Before that period, however, the government in India had been alarmed, by the same means, and was making preparations for war. This, however, was no easy matter. It is the nature of European power, in these countries, gradually to decline. The nature of the climate, the view of returning home, and the distance from the seat of government, speedily introduce a relaxation of the efforts and the vigilance by which dominion was originally acquired. The troops require to be continually renewed by levies from the parent country; and if this precaution is neglected for a very short time, or negligently attended to, they become unable to protect the extensive territories such as Britain now possessed in India. When Lord Mornington, the governor-general, enquired into the state of the British army at Madras, and whether he might hazard an offensive war against Tippoo; he was informed, that three, if not six months would be necessary to assemble the scattered divisions of the army, and to prepare them to defend their own territory. It was added, that such was the feeble state of the British forces in that quarter, that it might even be unsafe to excite suspicion in Tippoo by military preparations, as he might, in that case, ruin them by a sudden attack Lord Mornington, however, resolved to encounter every hazard, and ordered immediate and active preparations in every quarter.

390
His
[illegible] detected by the British.

In the meanwhile, Tippoo did not trust for success to the aid of France alone. He endeavoured to bring an attack upon the British and their allies, or subjects, in India, from the north-west, by inviting Zemaun Shah to invade the country. This prince is at the head of a formidable kingdom, made up of provinces torn from both Persia and India. It was founded about sixty years ago by Ahmed Khaun Abdalla, an Affghan chief, who followed Nadir Shah on his invasion of India in 1739. He himself afterwards invaded India no less than seven times; and, in particular, he overthrew, with dreadful slaughter, the united forces of the Mahratta empire, in the year 1761, on the plains of Paniput. He was succeeded, in 1773 by his son Timmur Shah, who died, and was succeeded by his own son, the present prince. The dominions of Zemaun Shah extend from the left bank of the river Indus, on the seacoast, as far northward as the latitude of Cashmeer; and from east to west they are 650 English miles in length, comprehending the provinces of Cabal, Candahar, Peishere, Ghizni, Gaur, Sigistan, and Korasun. He usually keeps in pay an army of 150,000 horse, besides infantry to garrison his fortresses. In expectation of direct aid from France, by Bonaparte's expedition to Egypt, and of an important diversion to be made by Zemaun Shah, Tippoo endeavoured to remain quiet, and to temporise with the British.

Since the [illegible] of Lawrence and of Clive, the native princes of India have been eager to introduce the European [illegible] their [illegible] For this purpose [illegible] to command and [illegible] endeavour to [illegible] of European soldiers. [illegible] British, [illegible] fluence, [illegible] able body [illegible] and of [illegible] ment. These under the command [illegible] possessed great influence at Hyd[illegible] the Nizam. It was of much [illegible] should be [illegible] to obtain [illegible] proaching [illegible] procured [illegible] success, that, on [illegible] French corps under Perou [illegible] without bloodshed, and a British force was [illegible] as a guard to the Nizam [illegible] The military preparations being in a considerable state of forwardness, Lord Mornington next warned Tippoo Sultan, in a letter dated the 8th of November 1798, of his having a knowledge of his hostile designs and connection with the French. He also proposed to send an ambassador to treat about the means of restoring a good understanding between the states. Tippoo avoided returning an answer till the 18th of December, and then merely denied the accusation, and refused to receive the ambassador. On the 9th of January 1799, the British governor again urged in writing that the ambassador should be received. No answer was returned for a month; and, in the mean time, an army of 5000 men having arrived from England, orders were issued to General Harris to advance at the head of the Madras army against the kingdom of Mysore. Tippoo now offered to receive the ambassador, providing he came without an attendance; but this concession was not accounted sufficient, and the army advanced. An army from

French Revolution 1799.

from Bombay was, at the same instant, advancing on the opposite side of his dominions. A part of Tippoo's forces encountered this army and were defeated; and within a few days thereafter, on the 27th of March, the rest of his army was defeated by General Harris. When an European army in India is tolerably numerous, the detail of its military operations against the natives is by no means interesting; for the inhabitants of these enfeebling and fertile regions can never be made, by any kind or degree of discipline, to possess that moral energy which enables men to encounter danger with coolness and self-command. They can rush on death under the influence of rage or despair, but they cannot meet the hazard of it with calmness and recollection. It is sufficient to remark that, on the 7th of April, General Harris sat down before Seringapatam. On the 9th, Tippoo sent a letter to this officer, alleging his own adherence to treaties, and enquiring into the cause of the war. He was answered by a reference to Lord Mornington's letters. On the 20th he made another attempt to negociate, by writing to General Harris, requesting him to nominate commissioners to treat of a peace. In answer to this [illegible], certain articles were sent to him as the only conditions that would be granted. By these he [illegible] required to surrender half his dominions, to pay a large sum of money, to admit resident ambassadors from the British and their allies, to renounce all [illegible] with the French, and to [illegible] stipulations. On the [illegible] to General [illegible] ambassadors; [illegible] that he [illegible] of peace [illegible] have [illegible] the in[illegible] was [illegible] effect of [illegible] in [illegible] troops to [illegible] till the [illegible] besiegers [illegible] a breach [illegible] on the 4th of May. [illegible] had been chosen for this purpose, as the hottest hour of the day, and consequently the time when it would be least expected. Tippoo was in his palace; but on being informed of the attack, he hastened to the breach, and fell undistinguished [illegible] conflict. [illegible] treasures, and the plunder of the city, which was immense, went to enrich the conquering army, after deducting a share for the British government and East India Company. His kingdom immediately submitted. The part of it which formed the ancient kingdom of Mysore, was bestowed upon a descendant of the former race of its kings, whom Hyder Ally had deprived of the sovereignty; the additional territories that had been conquered by Hyder Ally were divided between the British and their allies, the Nizam and the Mahrattas. The family of Tippoo were either taken in the capital, or voluntarily surrendered themselves to the conquerors. They were removed from that part of the country, and allowed a considerable pension.

In the mean time, Zemaun Shah had actually invaded India from the north-west. He advanced to the vicinity of Delhi, spreading terror and desolation wherever he came. Had the French army in Egypt been able to detach a body of 15,000 men to the assistance of Tippoo, while all India was in the state of alarm naturally produced by the approach of this northern invasion, it is extremely probable that the British forces might speedily have found themselves deserted by every ally, and sunk under an unequal contest. But the actual result was very different. Satisfied with the plunder he had obtained, Zemaun Shah soon withdrew; and the French army being detained in Egypt by the war with the Turks, and by the want of vessels at Suez wherewith to reach India, Tippoo was left to contend, unassisted, against the whole power of Britain, and of its allies in the east. By the conquest and division of his territory, the British power was left without a rival in that quarter of the world, and raised to such a state of imposing superiority, that if affairs are only preserved in their present situation, by periodical supplies of European troops, no native prince, or even combination of princes, can henceforth bring it into danger. Thus, notwithstanding the vast military efforts made by the people of France during this revolutionary war, yet all foreigners who trusted to their aid were ruined by placing confidence in them. In Italy, Germany, Switzerland, and Holland, the rapacity of the commissaries of the French government, soon rendered odious and intolerable the presence of those armies whose arrival had been eagerly desired. In Ireland and in India, the promise and the hope of assistance which they were never able to bestow, only served to produce premature hostility, and to encrease and establish the power of the British government. 393 Immense power of Britain in India.

But to return to the domestic history of France, which has now become only an history of the usurpation of Bonaparte.

394 New constitution of France.

In the middle of the month of December, the Consuls, with their legislative committees, produced to the public their plan of a new constitution, which they presented to the primary assemblies, and which is said to have been accepted by them without opposition, like all the former constitutions. It is a very singular production, and neither admits of representative government, nor indeed of any other form of political freedom. Eighty men, who elect their own successors, possess, under the appellation of a *Conservative Senate*, the power of nominating the whole legislators and executive rulers of the state; but cannot themselves hold any office in either of these departments. The sovereignty is concentrated in one man, who, under the title of *Chief Consul*, holds his power for ten years, and may be re-elected. The whole executive authority is entrusted to him, and he enjoys the exclusive privilege of proposing new laws. He is assisted by two other consuls, who join at his deliberations, but cannot controul his will. The legislative power is entrusted to two assemblies: the one, consisting of 100 members, called a *Tribunate*; and the other, of a *Senate*, of 300 members. When a law is proposed by the Chief Consul, the Tribunate may debate about it, but have no vote in its enactment. The Senate votes for or against its enactment, but cannot debate about it. Neither the Consuls, nor the members of the legislative bodies, nor of the conservative senate, are responsible for their conduct. The ministers of state, however, who are appointed by the

French Revolution, 1799. the Chief Consul, are responsible for the measures they adopt.

The people in the primary assemblies elect one-tenth of their number as candidates for inferior offices; persons thus chosen, elect one-tenth of themselves as candidates for higher offices; and these again elect a tenth of themselves as candidates for all the highest offices of the state. Out of this last tenth the Conservative Senate must nominate the consuls, legislators, and members of their own body. But this last regulation is to have no effect till the ninth year of the republic. In the mean time, the same committees that framed the constitution, appointed also the whole persons who were to exercise the government. Bonaparte was appointed Chief Consul, and Cambaceres and Lebrun second and third Consuls. Sieyes, with his usual caution, avoided taking any active share in the management of public affairs, and was appointed, or appointed himself, a member of his own Conservative Senate; the whole being regarded as produced by him. As a gratuity for his services, the Chief Consul and his legislators presented to him an estate belonging to the nation, called *Crosne*, in the department of Seine and Oise.

395 Absolute power of Bonaparte. Thus, after all their sanguinary struggles for freedom, did the son of a Corsican drive from their stations the representatives of the French nation, and assume quiet possession of the government of that country, with a power more absolute than ever belonged to its ancient monarchs. The established privileges of the clergy, the nobles, and the parliaments, always restrained, in some degree, the despotism of the kings of France; these being now destroyed, the will of Bonaparte could meet with no controul. Though an usurper, however, he has not hitherto been a tyrant. He has rather attempted to induce the French nation to acquiesce in his authority, in consequence of the mildness with which it has been exercised, and of the ability and reputation of the men whom he has employed in the public service. He immediately sent proposals for negociating peace to the different powers at war with France. Great Britain refused to listen to him on account of the probable instability of his government, and Austria appears to have given a similar refusal. It is indeed difficult to believe that he wished his proposals to be accepted. They were not addressed to the belligerent powers in the aggregate, but to each individually, as if his object had been to sow dissention and mistrust between the allies. When he made these proposals, he did not even know whether the people of France would accept of the constitution which he had offered them; and he had taken no measures to procure a repeal of those revolutionizing decrees which were the immediate cause of the war with England.

396 Difficulty of his situation. His situation is, in the mean time, attended with great difficulties. The want both of an hereditary title, and of a national representation as the basis of his power, renders his character as an usurper so obvious, that it is only by very cautious measures that his elevation can be maintained. If he is either unsuccessful abroad, or compelled to press the people for money at home, there is little doubt that his fall must follow. Even independent of either of these events, it is a possible case that the violent Jacobins may recover their lost energy, and by force or fraud destroy the man who has baffled all their projects. From the royalists he has less to fear; for the men of ardent spirits and violent passions belonging to that party, from whom alone great efforts can ever be expected, were early tempted to leave the country by the hopes held out to them by the coalesced powers, which, by weakening, has hitherto prevented their party from becoming of much importance in the interior of France.

1800. In the mean time, Bonaparte has been successful in suppressing a new royalist revolt which had arisen in La Vendee, and has made great exertions to begin the campaign with vigour. The low state of the French finances, however, have much enfeebled all his efforts towards assembling very numerous armies. The army which he left in Egypt, after concluding a treaty with the Grand Vizier, by the terms of which they were to be landed safe in France, have seen reason to break the truce which had been agreed on. Kleber has attacked and completely defeated the main body of the Turkish army, while a detachment of that army has entered Cairo, and massacred, it is said, every Frenchman found in the city, not sparing the members of the National Institute. The probable consequence of this is, that no part of the army of Egypt will ever return to Europe. 397 Army of Egypt.

War has been recommenced between the Austrians and France, both in Switzerland and in Swabia, and carried on with great vigour. Massena, after giving complete proofs of consummate skill, and the most undaunted valour, has been for some time blocked up in Genoa; and unless he has been relieved by the vigorous exertions of the Chief Consul, he must before this period (June the 12th) have surrendered to the Austrian General Melas. The affairs of the French in that quarter seem indeed to be [illegible]; but in Germany they have hitherto been successful. [illegible] wonted abilities, and the gallant [illegible] before him, whether from necessity or to [illegible] inextricable difficulties, a very short time will evince. 398 Recommencement of war in Europe.

But here we shall interrupt this detail, without the faintest prospect of bringing it to [illegible] during the publication of the [illegible]. We cannot, however, dismiss the [illegible] without correcting some errors [illegible] which we fell in the account of the rise and progress of this revolution which was published in the *Encyclopædia*. We do not consider these errors as di[illegible] to ourselves; for in the midst of commotions which have convulsed all Europe, it is hardly possible to arrive at the truth. When time shall have cooled the passions of men, and annihilated the parties which now divide the nation, the calm voice of Truth may be everywhere heard; but when the article referred to was written, the ears of every man was stunned with the clamour of faction. 399 Abrupt conclusion of this narrative. 400 Errors in the former part of the article corrected.

So sensible of this are the editors of the only impartial periodical history* which we have, that they venture not to publish their volumes till several years have elapsed from the era of the transactions which these volumes record; whilst their rivals—the panders of faction—seize the earliest opportunities of obtruding their partial statements and false reasonings on the public mind.

* *Old Annual Register.*

It cannot be supposed that one or two men, superintending the publication of a work so extensive, and treating of subjects so various, as ours, have leisure or opportunity to examine with much attention the correspondence of ambassadors, or to expiscate truth from the contradictory publications of the day. We are

French Revolution. therefore obliged to draw our materials from such works as profess to give a summary, but impartial, detail of what is acting on the theatre of the world; and by these works we have often been misled. For the first error, however, which we shall notice in our former account of the rise of the revolution, we cannot plead even this excuse. We ought to have known, that the French clergy and French noblesse were not exempted from the payment of taxes; and, of course, we ought not to have assigned such exemption as one of the causes of the REVOLUTION. See that article, *Encycl.* n° 8. and 9.

401 First error. By a writer, to whose patriotic exertions this country is deeply indebted, it has been proved, with a force of argument which precludes all possibility of reply, that the exemption from taxes so loudly complained of was very trifling, that it was not confined to the nobility and clergy, and that it did not extend over the whole kingdom of France. "The *vingtiemes*, which may be considered as an impost merely territorial, was paid alike by the nobility and the *tiers-etat*. A great part of the clergy was indeed exempted; but their contributions, under a different form, constituted an ample equivalent. The duties upon the different articles of consumption were of course paid by all the consumers, except that in the *pays d'etat*, such as Artois and Brittany; the two first orders were exempted from paying the tax upon liquors. But these exemptions cannot be deemed very important, when it is known, that in the province of Artois they did not exceed 800 guineas annually [illegible] including the exemptions enjoyed by the privileged members of the *tiers-etat*." The British officers [illegible] of war are exempted from [illegible] of the state on [illegible] believe no good subject has ever murmured at that exemption. The French nobility were subject to the pole-tax.

"Of the *taille*, the impost from which it has been falsely asserted that the nobility and clergy enjoyed a total exemption, there were two species; the one *personal*, the other *real*. In one part of the kingdom, the right of exemption was [illegible] to the [illegible]ty; in the other, to the quality [illegible] In the first case, the privilege was enjoyed by every class of persons, by the tenants as well as the proprietor of a fief; whilst the gentleman, whose estate was holden by a different tenure, was obliged to pay the tax. In those provinces where the other custom obtained, the exemption was confined to a certain extent of property, and to *that* only while it continued in the actual occupation of the privileged person; but as it very seldom happened that the French nobility kept any land in their own hands, and as the tax payable by the farmers was of course deducted from the rent, the *teilles* was, in this case, ultimately paid by the landlord. The same observations apply, with still greater force, to the clergy, who always let their estates."

In a word, it appears from a formal declaration made by M. Necker to the Constituent Assembly, that all the pecuniary exemptions enjoyed by the privileged classes did not exceed L.292,000; that the exemptions appertaining to the privileged persons of the *tiers-etat* amounted to one half of that sum; and the *drôits de contrôle*, or duty imposed upon public deeds, and the high capitation tax (proportioned to their rank), paid by the nobility and clergy, made ample amends to the revenue for the partial exemptions which they enjoyed from other taxes. So far indeed were the *tiers-etat* from murmuring at the exemptions of the privileged orders, that, previous to the illuminism of the 18th century, they displayed, at every convention of the states-general, the greatest anxiety to maintain the rights of the nobility and clergy; and humbly supplicated their sovereign to suffer no invasion thereof, but to respect their franchises and immunities *.

* See Gifford's Letter to the Earl of Lauderdale, 2d ed.

We must likewise acknowledge, that in n° 11. of our article REVOLUTION, we have drawn a very overcharged picture of the miseries and oppression of the French peasants under the old government. It is indeed true, 402 Second error that they were obliged to serve in the militia, the establishment of which was conducted in France nearly on the same principles as it is in England. The men were called out by ballot only for a few days in the year during peace, when they received regular pay; but if a militia forms the best constitutional defence of a state, this surely ought not to have been considered as a grievance, especially since married men were exempted from the service. The nobility, too, were exempted from the risk of being drawn, for the best of all reasons—because most of them had commissions in the regulars, and because such as had not were engaged in professions, which rendered it impossible for them to serve in the militia. In France, as elsewhere, the peasants would no doubt be averse from this service, and might look perhaps with an anxious eye to the supposed immunities of their privileged superiors: but if mirth, good humour, and social ease, may be considered as symptoms of felicity and content, these men surely were not miserable; for these symptoms never appeared in any people so strong as among the French peasants. They were indeed liable to be called out by the intendants of the provinces to work a certain number of days every year on the public roads; but to this species of oppression, if such it must be called, the Scotch peasants are liable, and were still more so than at present, during that period when our parliamentary orators declare that the inhabitants of Britain enjoyed as much freedom as is consistent with the public tranquillity. It ought to be remembered, too, that Louis XVI. whose highest gratification seems to have consisted in contributing to the ease and welfare of his subjects, thought he saw the necessity of abolishing the custom of the *corvée*, and had made considerable advances towards the accomplishment of that object some years before the commencement of the revolution.

403 The French monarch not despotic. That the French monarch was despotic; that no man in the kingdom was safe; that nothing was unknown to the jealous inquisition of the police; and that every man was liable, when he least expected it, to be seized by *lettres de cachet*, and shut up in the gloomy chambers of the Bastile—has long been common language in England, and language which we must confess that we have adopted (REVOLUTION, n° 12.) without due limitations. The French government was certainly not so free as that of Britain; but he who understood it better than we do, and whose writings betray no attachment to arbitrary power, expressly distinguishes between it and *despotism*. "If (says Montesquieu) France has, for two or three centuries past, incessantly augmented her power, such augmentation must not be ascribed to fortune, *but to the excellence of her laws* †."

† De l'Esprit des Loix, liv.

This

French Revolution.

This, furely, is not the language of a man who thought himfelf governed by an arbitrary tyrant whofe *caprice* is the law; nor will it be faid to be the language of one who was either afraid to fpeak the truth or not mafter of his fubject.

404 No charge of the old conftitution wifhed by the people of France.

The inftructions of all the different orders to their reprefentatives, before the fatal meeting of the States General under the unfortunate Louis, are drawn up in language fimilar to that of this illuftrious magiftrate, and furnifh a complete proof that they knew themfelves to be fafe under the government of their monarchs. "The conftitution of the ftate (fay the clergy) refults from the *fundamental laws*, by which the refpective *rights* of the *king* and of the *nation are afcertained*, and from which not the fmalleft deviation can be made. The firft of thefe laws is, that the government of France is purely monarchical. The nation muft preferve inviolate the form of its government, which it acknowledges to be a *pure monarchy regulated by the laws*; and fuch it will have it to remain."

On the 28th of November 1788, in a general committee of the nobles affembled at Verfailles, the Prince of Conti delivered a note to the prefident, which was fanctioned by the concurrence of moft of the other princes of the blood, and was fuppofed to fpeak the general fenfe of the nobility; in which it was infifted, that the *profcription of all* NEW SYSTEMS *was neceffary* to infure the ftability of the throne, of *the laws*, and of *order*; and that the conftitution, *with the ancient forms*, fhould be preferved entire. In their inftructions to their reprefentatives, they infift that it fhall be exprefsly and folemnly proclaimed, that the conftitution of the French empire is fuch, that its government is, and muft remain, monarchical; that the king, as fupreme chief of the French, is only fubordinate to the fundamental law of the kingdom, according to which the conftitution muft be eftablifhed on the facred and immutable principles of monarchy, tempered by the laws; and this form of government cannot be replaced by any other conftitution.

"Let our deputies (fays the third eftate), before they attend to any other object, affift in giving to France a truly monarchical conftitution, which muft invariably fix the *rights* of the *king* and of the *nation*. Let it be declared, that the monarchical is the only form of government admiffible in France; and that in the *king alone*, as chief of the nation, is vefted the power of *governing according to the laws*." Is this the language of men groaning under the iron rod of defpotifm, or wifhing to reduce the power of the crown?

Even after the power of the crown was almoft annihilated and the order of nobility done away, fo far were thefe innovations from being acceptable to the enlightened part of the French nation, that in many departments of the kingdom they excited open infurrections, whilft the members of all the provincial parliaments oppofed them with unanfwerable arguments furnifhed by the law. The chamber of vacation of the parliament of Touloufe, in particular, protefted againft the proceedings of the States General, becaufe the deputies, who were empowered only to put an end to the ruinous ftate of the finances, could not change the conftitution of the ftate without violating their inftructions, and the faith fworn to their conftituents *.

* See the proteft at large in *Bertrand's Mem.* vol. i. c. 13.

That *lettres de cachet* were liable to abufe, and that occafionally they were grofsly abufed, is certain. The ufe of them ought therefore to have been either annulled, or, which would have been infinitely better, fubjected to fuch rules as fhould prevent all danger from them to the real liberties of the people; for the government would be of no ufe whatever which fhould poffefs no power capable of being abufed by defpotifm. Yet after all the noife that has been made about *lettres de cachet*, it is but juftice to obferve, that in the towers of the Baftile, when it was taken by the mob, were found no more than feven prifoners; of whom four were confined for forgery; one was confined at the requeft of his family on charges of the moft ferious nature; and two were fo deranged that they were fent next day, by thofe philanthropifts who had taken them out of comfortable chambers, to the mad houfe! That the chambers of the Baftile were as comfortable as the chambers of a prifon could be, we are affured by M. Bertrand de Moleville, who can be under no inducement to deceive the Britifh public, and whofe opportunities of difcovering the truth were fuch as no man will call in queftion.

405 Lettre de cachet.

406 Blunder of Necker.

In our account of the opening of the States General, we have expreffed too much deference to the character of M. Necker. To that man's irrefolute, if not treacherous, conduct, may, with truth, be attributed all the fubfequent miferies of France. It was about the mode of verifying their powers that the [illegible] ftate firft [illegible]; but this mode fhould have been defined by [illegible] different bailiwicks [illegible]. Even this omiffion [illegible] of the deputies at [illegible] been admitted into the hall of [illegible] the king have [illegible] fatisfied [illegible] thefe cau[illegible] have got the afcendant over the other [illegible] the bufinefs of the [illegible] as formerly [illegible] rejection [illegible] ill qualified [illegible] fis; and his abfenting [illegible] meafure which he [illegible] betrayed [illegible] ingratitude to his gracious [illegible].

In our account of the royal feffion, we were led into a miftake, which calls loudly for correction. The circumftances of that feffion were very different from what they appeared to us when we wrote n° 24. and 25. of the article REVOLUTION. The royal feffion was proclaimed in confequence of the violent ufurpations of the *tiers-etat*, and the irreconcileable differences which fubfifted between that body and the two higher orders; and fo far is it from being true that the prefident and members of the third eftate found their hall *unexpectedly* furrounded by a detachment of guards, that their fittings were only *fufpended*, for the beft of all reafons, with thofe of the other orders. To be convinced of this, we need but to attend to the following proclamation which was made by the heralds, on the 20th of June, between feven and eight o'clock in the morning, in the ftreets and crofs-ways of Verfailles:

407 Royal Seffion.

"June 20th. (By order of the King.) The King having refolved to hold a royal fitting in the States General, on Monday next the 22d of June, the preparations to be made in the three halls ufed by the affem-

French Revolution.

blies of the orders, make it neceſſary that thoſe aſſemblies ſhould be ſuſpended until after the ſaid ſitting. His Majeſty will give notice, by another proclamation, of the hour of his going to the Aſſembly of the States on Monday."

M. Bailly, the preſident of the *tiers-etat*, had been made acquainted with the object of this proclamation, by a private letter which was ſent to him by the Marquis de Brezé at ſeven o'clock in the morning; and to which he replied, "that having received no orders from the King, and the aſſembly having been announced for eight o'clock, he ſhould attend where his duty called him."

He repaired, accompanied by a great number of the members of the *tiers-etat*, to the door of the hall of the States, demanded admiſſion: and on being refuſed by the officer on guard, according to his orders, with which he acquainted him, he declared that he proteſted againſt ſuch orders, and that he ſhould give a report of them to the Aſſembly. To do this he had not far to go, as three-fourths of the deputies of the *tiers-etat*

408 Factious insolence of the aſſembly.

were already collected round him, or in the avenue leading to the palace. There it was that, ſurrounded by an immenſe crowd of people, they declaimed in the moſt violent manner againſt this pretended act of deſpotiſm. "The National Aſſembly is to be diſſolved (ſaid they), and the country to be plunged into the horrors of a civil war. *Want* rages every where; every where the people *ſee famine* ſtaring them in the face. This we were about to put an end to, by tearing the veil which [illegible] the mono[illegible]s, the [illegible] of miſcreants. The [illegible] the Richelieus, the Mazarins, [illegible] with their deſpotiſm only indi[illegible]; but here it is the whole nation [illegible] made the ſport of the whims of a deſpot miniſter. [illegible] upon the *Place d'Armes* (ſaid [illegible]); there we ſhall recal ſome [illegible] the [illegible] the *National Aſſemblies of* [illegible] in the gallery of the [illegible] new light, by [illegible] the language of liberty in this corrupt hall, where a little while ſince the head of him who ſhould have uttered that ſacred word would have been devoted to [illegible] executioner.—"No, no (ſaid a third), let us go to Marli, and hold our ſitting on the Terrace;—let the King hear us; he will come from his palace, and will have nothing more to do than to place himſelf in the midſt of his people to hold the royal ſitting."

At the concluſion of theſe declamations, the ſole object of which was to alarm and exaſperate the people, the Aſſembly decided upon transferring their ſitting to the Tennis-court, in the ſtreet called *Rue du Vieux Verſailles*. There M. Bailly read the letter which he had received from M. de Brezé, and his anſwer to it; which he had ſcarcely done, when a ſecond letter from M. de Brezé was put into his hands, the contents of which were as follows:

"It was by the King's poſitive order, Sir, that I did myſelf the honour of writing to you this morning, to acquaint you that, his Majeſty purpoſing to hold a royal ſitting on Monday, and ſome preparations being requiſite in the three halls of the Aſſemblies of the orders, it was his intention that no perſon ſhould be admitted into them, and that the ſittings ſhould be ſuſpended till after that to be held by his Majeſty."

French Revolution.

In this there was ſurely no marked diſreſpect to the repreſentatives of the people; but ſuch notions were countenanced by M. Necker, who appears indeed, on this occaſion, to have been in cloſe compact with the leaders of the mob. The popular violence that was employed to compel the majority of the clergy to join the *tiers-etat* is well known; and we have, in *Bertrand's Annals of the Revolution*, what amounts to dence almoſt *legal*, and quite ſufficient to enforce conviction, that Necker directed that violence.

In our account of the commotions which were excited in Paris on the firſt diſmiſſion of that miniſter and his baniſhment from the kingdom, we have been led by our democratic journaliſts to give circulation to a groſs calumny publiſhed by them againſt the Prince de Lambeſc. (See REVOLUTION, n° 36. and 37.) The truth, which is ſo much diſguiſed in theſe two numbers, is as follows:

"A detachment of the Royal Allemand, ſent to diſperſe the mob which was patroling the ſtreets in proceſſion with the buſts of Necker and the infamous Orleans, received a volley from the French guards as they were paſſing their quarters on the *Chauſſée d'Antin*, ſtopped to return it, and continued their march without quickening their pace. There were ſome ſoldiers killed and wounded on both ſides, but fewer of the regiment of Royal Allemand than on that of the French guards. 409 Conduct of the Prince de Lambeſc vindicated.

"The detachment marched to the Place Louis XV. and there found a body of dragoons who had been diſperſing the proceſſion. The two buſts were broken to pieces; and the populace in their fright taking refuge in the garden of the Thuilleries, the Prince de Lambeſc purſued them thither, at the head of the detachment of Royal Allemand, according to the orders which he received. This ſmall troop coming up to the head of the *Pont-tournant* (or turning bridge), at the extremity of the garden, found a kind of barricade, haſtily formed by chairs heaped upon one another: while they were removing this obſtacle, they received a ſhower of ſtones, broken chairs, and bottles, from the two terraces, between which the Prince de Lambeſc drew up his troop, keeping conſtantly at their head. Some guns and piſtols were diſcharged at them, which did no hurt; but ſeveral of the troopers were much bruiſed by the things that had been thrown at them, and an officer was ſeverely wounded by a ſtone.

"The Prince de Lambeſc, keeping at ſix paces from the bridge, oppoſed only a ſteady front to the aggreſſions of the populace. Seeing that this poſt became untenable, and that it was impoſſible for him any longer to reſtrain his troopers from repelling force by force, he gave the order for retreating out of the garden. At the ſame inſtant a cry was heard from all ſides of, *turn the bridge, turn the bridge*; and ſome perſons, in conſequence, ran and began to do it. The Prince de Lambeſc, juſtly fearing that a moſt bloody carnage would be the inevitable conſequence of it, ordered ſome piſtols to be fired in the air towards the bridge, to awe thoſe who were ſtriving to turn it. As the report of this volley did not deter them, he rode up himſelf, and with his ſabre ſtruck one of thoſe who were working hardeſt. The man ran off; and the Prince paſſing the bridge with

French Revolution. with his detachment into the Place Louis XV. drew up near the Statue, and being soon joined by the Swiss regiment of Chateauvieux, took his post with this force near the *Garde-meuble*, where he remained some time, having placed the infantry before him. At ten at night part of the troops were dismissed to their quarters, and the rest sent to Versailles." These facts being all judicially confirmed, prove how much the Prince de Lambesc's conduct was calumniated by those journalists whose detail we rashly adopted.

410 True account of the taking of the Bastile; In our account of the taking of the Bastile, misled by our treacherous guides, the journalists, we have greatly magnified the military skill and prowess of the assailants. That celebrated fortress was defended by a garrison consisting of no more than 114 men, of whom 82 were invalids. It was attacked by 30,000 men and women, armed with muskets and pikes, and furnished with a train of artillery which they had found at the *Hotel des Invalids*, given up to them by the timidity of the governor. Even this multitude would have been quickly repulsed from the Bastile, if the governor of that state-prison, who had received no orders from the court, had been less reluctant to shed the blood of his rebellious countrymen; for the Parisian mob had then displayed nothing of determined courage. A few discharges of musquetry, and one of canister-shot from a single cannon, had thrown them into confusion, and made them skulk behind the walls, when the ill-timed humanity of the governor made him enter into a treaty with the rebels, stipulating only that the garrison should not be massacred. How the stipulation was observed with respect to the governor himself, we have faithfully related; but we were mistaken when we said that the "French guards succeeded in procuring the safety of the garrison." The guards, with the utmost difficulty, saved indeed some of them, but most of the invalids remaining in the courts of the castle were put to death in the most merciless manner.

411 And of the murder of M. de Flesselles. Our account of the murder of M. de Flesselles (nº 40.) appears likewise to be very incorrect. This man was president of the Assembly of Electors at Paris (See REVOLUTION, nº 45.), and had not quitted the *Hotel de Ville*, where their rebellious meetings were held, during the whole time of these dreadful commotions. He had even signed all their atrocious resolutions, but became suddenly suspected from the consternation which he manifested at the sight of so many horrors, and especially at the cruel and treacherous murder of the governor of the Bastile. The consequence was, that he was treacherously murdered himself by one of the villains composing that assembly in which he presided. "The electors (says M. Bertrand de Molleville) hoped to extenuate the horror of this assassination, by causing it to be considered as a natural and almost lawful vengeance for a treachery, the proof of which they pretended to have. In fact, they declared, that when M. de Launay, the governor of the Bastile, was arrested, a letter had been found in his pocket from M. de Flesselles, containing this expression: 'I am amusing the Parisians with cockades and promises; hold out till night, and you will receive a reinforcement.' But this supposed letter, which, had it existed, they would not have failed to preserve very carefully, was never seen by any body; and I heard M. Bailly himself say, in a visit he paid me when he left the mayoralty, that he had no knowledge of it, and that it was not in his power to refer to any one who had told him that he had read it."

412 Ambition and cowardice of the Duke of Orleans. In our account of the earlier transactions of the Revolution, we omitted to mention a very extraordinary instance of ambition to which the Duke of Orleans was incited by Count Mirabeau, but which that unnatural monster wanted courage to carry into effect. During the commotions which prevailed in the capital on the dismissal of M. Necker from the ministry, Orleans was persuaded by Mirabeau to offer his services as mediator between the king and his rebellious subjects; but to stipulate, at the same time, for his appointment to the high office of lieutenant-general of the kingdom as necessary to give his mediation due weight with the rebels. The real object of the profligate Count, in this dangerous proposal, and which he did not deign even to conceal, was to pave the way for the infamous Duke stepping into the throne of his relation and virtuous sovereign. He even went so far as to compose the speech with which Orleans was to address the king on the occasion; but that coward, when he arrived at the palace, was so embarrassed by the consciousness of his own wicked designs, that instead of asking the office of lieutenant-general, he only requested permission to retire into England!! A request which was instantly granted.

This brought upon him the contempt and indignation of Mirabeau; but still there was a party desirous of placing him on the throne. This we think evident from an atrocious [illegible] mentioned in all the journals, and confirmed by M. Bertrand. When the king, on his first visit to Paris (See nº [illegible]) [illegible] the *Champ Elisées*, three or four guns were fired at once. It was never known whence they proceeded; but it is certain that an unfortunate woman in the crowd, who was in the direction of his Majesty's carriage, was shot at the time, and fell dead on the spot. As the King's carriage held at the time [illegible] four persons, M. Bertrand very naturally con[illegible]es that these four shots, fired at once in its direction, had been ordered and paid for; and we are unwilling to believe that at that period of the revolution there was any party disposed to pay for the murder of the sovereign but the Duke of Orleans and his infamous adherents. That he was equal to this wickedness cannot be doubted, when it is known that legal evidence was afterwards produced that he, with some other members of the Assembly, secretly directed the insurrection of the 5th of October, and promoted the outrages of that and the succeeding day by the distribution of money and bread *.

413 M. Memmay vindicated. We have said (nº 48.), the origin of the report of a train of gunpowder being laid by M. de Memmay, to blow into the air a number of patriots, has never been well explained. It was proved judicially, that at the period when the feast was given by M. Memmay to the inhabitants of Vesoul, he was setting vines in a stony soil, where he was often obliged to blow up the greater rocks. Some soldiers running through, and ferreting every where in the house and out-houses, unfortunately took a candle to the dark corner where the barrel of gunpowder was lodged, and set it on fire, in trying to see if it contained wine. These facts, reported and attested in a memorial drawn up by M. Courvoisier, so completely justified M. de Memmay, that the Assem-

* Bertrand's Annals, vol. ii. ch. 13.

French Revolution. bly could not avoid testifying his innocence by a decree issued the 4th of June.

414 The power of the assembly in danger of being recalled by its constituents. In n° 70. we have said that the National Assembly, after its removal from Versailles to Paris, was in tolerable security; but M. Bertrand has proved, by evidence the most incontrovertible, that it did not think itself secure; and that if the ministers had been capable of employing events to their own advantage, the powers of that factious body must have been recalled by its own constituents. The horrible outrages committed on the 5th and 6th of October had shocked all France. The wanton confiscation of the property of the church, had demonstrated to every man of sound judgment, that under the new order of things no property could be secure; and by the desertion of its more virtuous and moderate members, the Assembly had become *a rump assembly*. It was therefore much alarmed when the intermediate commission of the states of Cambresis entered, on the 9th of November, into a resolution, in which, considering—"that certain decrees of the National Assembly are paving the way for the ruin of the kingdom, and the annihilation of religion; that if they have been able to place one species of property at the disposal of the nation, men of all kinds of property may expect the same fate; they declare, from this moment, the power of the deputies of Cambresis to the National Assembly to be null and revoked." Had M. Necker and his colleagues had address to get similar resolutions entered into at the same time by the electors of all the bailiwicks of the kingdom, the Assembly must have been dissolved, and France, even then, might have been saved; but those ministers were themselves nothing more than the humble and docile agents of the Assembly.

415 Account of the red book. [illegible]ere is no part of our former narrative more incor[illegible] or more likely to mislead the public, than our ac[illegible] of the *red-book* (n° 75.). It is such, however, [illegible] without any addition or aggrava[illegible] [illegible]lains (x) who, in direct contradic[illegible] their own solemn promise, as well as to every principle of honour, made part of that book public, had the impudence to affirm, that, by the suppression of the superfluous pensions registered in it, a saving would be made to the public *of near a fifth in the bulk of the expences of every year*. M. Bertrand, taking for granted the accuracy of their statements, for the exaggeration of which, however, he urges arguments more than plausible, proves, if arithmetical calculation affords proof, that by the suppression of such pensions as even *they* called superfluous, the saving in the bulk of the annual expences could not possibly have amounted to more than *the two hundredth part!* It was not therefore without reason that M. Necker, in answer to their publication, said, "I know not whether the books of the finances of any sovereign in Europe can shew a similar total."

416 And of the mutiny at Nancy. Our account of the mutiny of the soldiers at Nancy (n° 83.) is very inaccurate. Far from being excited by the officers, that mutiny was the natural consequence of the absurd decrees of the Assembly; which having declared *all men equal*, and made it criminal to punish disobedient soldiers in that summary way, without which no armed force can be commanded, had completely disorganised the army, and substituted for martial law patriotic exhortations, legislative decrees, and the novel jurisdiction of municipalities. The soldiers knew their own strength, of which indeed they were continually informed by the friends of the revolution; and while they shook off the authority of their military commanders, they laughed at the impotent decrees of the Assembly. At Nancy they had imprisoned two general officers, and committed other outrages of the most serious nature. It was the duty of the Marquis de Bouillé, as governor of the province, to reduce the insurgents by force, if force should be found necessary; but he had accomplished his object without shedding blood, and was congratulating the two liberated generals, and some of the principal inhabitants, upon so happy a termination of the affair, when the populace, and many soldiers who had not followed their colours, fired upon the troops under his command, and killed fifty or sixty men. The troops immediately returned the fire; and a great number of the rebellious mob and mutinous garrison were of course put to the sword. That such able and firm conduct in Bouillé excited indignation among the Jacobins of Paris, is very probable; but even the king himself did not express higher approbation of it than the National Assembly, who were duly sensible that it saved themselves from destruction, which, had he failed in his enterprise, would have been inevitable. Three months afterwards, indeed, when the fabrication of counter-revolutionary plots became part of the daily business of this enlightened Assembly, some censures were thrown by the Jacobins upon the Marquis's conduct on this occasion; and those censures were loudly applauded.

417 M. de Bouillé vindicated. We have likewise been led, by our fallacious guides, to accuse this gallant officer (n° 91.) of having laid open the country to the inroads of foreign armies; and we have given an incorrect account of the king's flight from Paris. There is no evidence whatever for the truth of the charge against the Marquis de Bouillé, and it is directly contrary to his general character. He was indeed a royalist, and would doubtless have cooperated with the Prince of Condé and the other emigrants in restoring the king to his lawful authority; but he was likewise a Frenchman and a patriot in the best sense of the word; and he would have died in defence of the rights and independence of his country. He certainly meant to protect the king in his journey from Paris to Montmedi, where it was to terminate; and he had stationed troops of dragoons on the road for that purpose; but the unfortunate Louis had delayed his journey a day longer than was agreed upon; and even when he set out, neglected to send couriers before him to warn the troops of his approach. He thus travelled unprotected; and the consequence was such as we have related. Yet the gallant Bouillé, tho' this journey was undertaken contrary to his advice, declared himself the author of it, in that letter in which he threatened the Assembly with vengeance of all Europe

(x) These were the Marquis de Montcalm-Gozon, Baron Felix de Wimpfen, de Menou, Fieteau, L. M. de Lepeaux, the Abbé Expilly, Camus, Goupil de Prefeln, Gautier de Biauzat, Treilhard, Champeaux-Palasne, and Cottin.

French Revolution.

rope if they should dare to touch a hair of the heads of the royal family.

418 Erroneous account in n° 90. corrected.

In n° 90. we have most unaccountably said that the king was permitted to continue his journey to St Cloud. This is directly contrary to truth. The president, after hearing his complaint against those who had prevented it, replied indeed in a speech, containing some expressions of gratitude and affection, mixed with reflections on the refractory priests; but the Assembly determined nothing respecting the propriety of the journey. They did not even suffer a single motion to be made on the subject; and threatened with imprisonment one of the members who proposed to take it into consideration! The king was therefore obliged to abandon this excursion, though it was first undertaken from religious motives; and it was then that he seriously thought of attempting to elude the vigilance of his rebellious guards, and of taking up his residence at Montmedi.

419 Treaty of Pavia a forgery.

In n° 96. we have published, with doubts indeed of its authenticity, what was called the *treaty of Pavia* and the *convention at Pilnitz*. The terms in which we introduced that scandalous fabrication to the notice of our readers, and the principles which we have uniformly avowed through the whole of this voluminous work, furnish, we hope, sufficient evidence that we could have no intention to deceive the public. Truth, however, demands of us to acknowledge, in the most explicit terms, that the pretended treaty of Pavia is not only a forgery, but a bungling forgery, defective in some of the most usual diplomatic forms; and that the conferences at Pilnitz between the Emperor, the King of Prussia, and the Count d'Artois, related to objects very different from a partition of the French territories.

So early as the month of May 1791, a plan had been digested by the Emperor, the King of Prussia, and the King of Spain, with the concurrence of Louis XVI. for liberating that unfortunate monarch from the confinement in which he was kept in his own capital. The means to be employed were a coalition among the principal powers on the continent to lead armies in every quarter to the borders of France. During the alarm which so menacing an appearance could not but excite in that kingdom, a declaration by the house of Bourbon, complaining of the cruel and iniquitous treatment of its head, was to be circulated through France, and to be immediately followed by the manifesto of the combined powers. This, it was presumed, would furnish a sufficient reason, even to the National Assembly, for the king's going to the frontiers, and placing himself at the head of the army; but if it should not, petitions were to be procured from the army and the provinces, requesting his presence, as the only means left of preventing a civil as well as foreign war. Had this measure, which was partly suggested by Mirabeau and partly by Montmorin and Calonne, been steadily pursued, there can be little doubt but it would have proved completely successful. It was defeated, however, by the king's ill-concerted attempt to escape to Montmedi, and by a very imprudent and degrading letter which he was afterwards persuaded to send to every foreign power.

420 Real convention at Pilnitz.

At Pilnitz, where the Emperor and the King of Prussia met, on the 25th of August, to settle between themselves some interests too delicate to be adjusted by the usual diplomatic modes, an agreement was entered into by them to support the cause of the French princes, to liberate the king, and to save, if possible, the monarchy. They delivered, accordingly, to the Count d'Artois the following declaration:

"His Majesty the Emperor, and his Majesty the King of Prussia, having heard the desires and the representations of Monsieur and his Royal Highness the Count d'Artois, declare, conjointly, that they consider the situation in which his Majesty the King of France is at present placed, as a matter which concerns the interest of every sovereign of Europe.—They hope that that interest will not fail to be acknowledged by the powers whose assistance is required; and that consequently they will not refuse to employ, in conjunction with their Majesties, the most efficacious means, according to their abilities, to put the King of France in a situation to establish, in perfect liberty, the foundations of a monarchical government, equally agreeable to the rights of sovereigns and the welfare of the French; then, and in that case, their Majesties are determined to act promptly and by mutual consent, with the forces necessary to obtain the end proposed by all of them. In the mean time they will give orders for their troops to be ready for actual service.

"*Pilnitz, August 27th, 1791.*

"Signed by the Emperor and the King of Prussia."

Such was the agreement entered into at Pilnitz, which was so grossly misrepresented by the French Jacobins, and by their zealous partizans in this country. Had not Lou[illegible]
and uncondit[illegible]
might have been[illegible]
and the prese[illegible]
ceptance, so little[illegible]
powers, completely[illegible] jes;
and before their armies[illegible]
narchy was overturned.

421 The Fre[illegible] the aggres[illegible] in the [illegible] with Britain.

In our account of the [illegible]
Great Britain an[illegible]
ved, by evidence[illegible]
that the French regi[illegible]
the British ministry[illegible] be[illegible]
ently with the independence of their own country, to maintain the relations of amity between the two nations. That we have interpreted fairly that decree of the Convention by which this kingdom was forced into the war, is rendered incontrovertible by a subsequent decree on the 15th of December, by which their generals were ordered to regulate their conduct in the countries which their armies then occupied, or *might afterwards occupy*. In the preamble to this decree, they expressly declared, that *their principles would not permit them to acknowledge any of the institutions militating against the sovereignty of the people*; and the various articles exhibit a complete system of demolition. They insist on the immediate *suppression of all existing authorities*, the *abolition of rank and privilege* of every description, and the *suppression of all existing imposts*. Nay, these friends to freedom even declare, that they will treat as enemies *a whole nation* (un peuple entier) which shall presume to *reject liberty and equality*, or enter into *a treaty with a prince or privileged casts!*

It is worthy of remark, that *the very day* on which this decree, containing a systematic plan for disorganizing all lawful governments, passed the Assembly, the provi-

French Revolution.

provisional executive council wrote to their agent, Chauvelin, instructing him to disavow all hostile intentions on the part of France, and to proclaim her detestation of the idea of a war with England! Yet the same provisional council, in their comments on the 11th article of this decree, thus express themselves: "The right of natural defence, the duty of securing the preservation of our liberty, and the success of our arms, the universal interest of restoring to Europe a peace, *which she cannot obtain but by* THE ANNIHILATION OF THE DESPOTS *and their satellites*, every thing imposes on us the obligation of exercising all the *rigours of war*, and the *rights of conquest*, towards a people so fond of their chains, so obstinately wedded to their degradation, as to refuse to be restored *to their rights*, and who are the accomplices, not only *of their own despots*, but even of all the *crowned usurpers*, who divide among themselves the dominion of the earth and its inhabitants." That Britain is one of those countries which the assembly thought their armies might afterwards occupy, and that the great majority of Britons were a people towards whom their principles obliged them to exercise all the rigours of war, and the rights of conquest, is evident from the following extract of a letter, written on the 31st of December 1792, by Monge, a member of the council, and minister of the marine to the sea-ports. "The King and his [illegible] war upon us. Will the [illegible]? Already [illegible] and the repug[illegible] against *their* [illegible] to their suc[illegible] island; we will [illegible] will plant there [illegible] our arms to our [illegible] *of their govern*[illegible]

[illegible] November and December [illegible] object is [illegible] executive [illegible] marine, [illegible] adopt as [illegible] and de Molleville*. [illegible] but perspicuous view of the rise and progress of that revolution, or, to speak more correctly, that series of revolutions which has for seven long years oppressed, not France alone, but all Europe, we shall conclude this long article.

* Introduction to the *Annals of the French Revolution*.

Rise and progress of the revolution.

"Popular [illegible], and an army (says this able and useful [illegible]) [illegible] hitherto been the usual means, or chief instruments, of every revolution; but those insurrections being of the most ignorant and unthinking class of the people, were always fomented by a certain number of factious men, devoted to, and dependent upon, some ambitious chief, daring, brave, of military talents, sole and absolute conductor of every step of the revolt, and master of all the means of the insurrection. In the hands of this chief, the soldiers, or people armed, were but machines, which he set in motion or restrained according to his pleasure, and of which he always made use to put an end to revolutionary disorders and crimes, as soon as the object of the revolution was gained. So Cæsar and Cromwell, after they had usurped the supreme power, lost no time in securing it to themselves, by placing it on the basis of a wise and well-regulated government; and they employed, in quelling the troubles that had favoured their usurpation, those very legions, that same army, which they had used to excite them.

"This was not the case in France: there, the revolution, or rather the first of those it experienced, and of which the others were the inevitable consequence, was not, whatever be supposed, the result of a conspiracy, or preconcerted plan, to overturn the throne, or to place an usurper upon it. It was unexpectedly engendered by a commixture of weakness, ignorance, negligence, and numberless errors in the government. The States General, however imprudent their convocation may have been, would have produced only useful reforms, if they had found the limits of their power marked out by a hand sufficiently firm to have kept them within that extent. It was, however, but too evident that, even before their opening, they were dreaded, and that consequently they might attempt whatever they pleased. From that time, under the name of *Clubs*, various associations and factions sprang up; some more violent than others, but all tending to the subversion of the existing government, without agreeing upon the form of that which was to be substituted: and at that juncture also the projects of the faction, whose views were to have the Duke of Orleans appointed lieutenant-general of the kingdom, began to appear.

"This faction, or more properly this conspiracy, was indeed of the same nature as those that had produced all former revolutions, and might have been attended with the same consequences, had the Duke of Orleans been possessed of that energy of character, that bravery and daring spirit, requisite in the leader of a party. The people had already declared in his favour, and he might very easily have corrupted and brought over a great part of the army, had he been equal to the command of it: but, on the very first occasion of personal risk, he discovered such cowardice and meanness, that he defeated his own conspiracy, and convinced all those who had entered into it, that it was impossible to continue the revolution, either in his favour or in conjunction with him. The enthusiasm the people had felt for him ended with the efforts of those who had excited it.

"Mr Necker, whom the multitude had associated with him in their homage, still preserved for some time his adorers, and that little cabal which was for ever exalting him to the skies. But as he was inferior even to the Duke of Orleans in military talents and dispositions, he was as little calculated to be the leader of a revolution, or of a great conspiracy: for which reason his panegyrists then confined themselves in their pamphlets and placards, with which the capital was overrun, to insinuating, that the only means of saving the state was to declare Mr Necker *Dictator*; or at least to confer upon him, under some title more consistent with the monarchy, the authority and powers attached to that republican office. In fact, if after his dismission, in the month of July 1789, he had dared to make this a condition of his return to the ministry, it is more than probable that the king would have been under the necessity of agreeing to it, and perhaps of re-establishing in his person the office of mayor of the palace. At that moment he might have demanded any thing: eight days later, he might have been refused every thing: and

French Revolution.

and very soon after, he was reduced to sneak out of the kingdom, in order to escape the effects of the general contempt and censure which he had brought upon himself.

"General La Fayette, who then commanded the Parisian National Guard, gathered the wrecks of all this popularity, and might have turned them to the greatest advantage, if he had possessed 'that resolute character and heroic judgment' of which Cardinal de Retz speaks, and 'which serves to distinguish what is truly honourable and useful from what is only extraordinary, and what is extraordinary from what is impossible.' With the genius, talents, and ambition of Cromwell, he might have gone as great a length; with a less criminal ambition, he might at least have made himself master of the revolution, and have directed it at his pleasure: in a word, he might have secured the triumph of whatever party he should have declared himself the leader. But as unfit for supporting the character of Monk as that of Cromwell, he soon betrayed the secret of his incapacity to all the world, and was distinguished in the crowd of constitutional ringleaders only by his three-coloured plume, his epaulets, white horse, and famous saying—'Insurrection is the most sacred of duties when oppression is at its height.'

"The revolution, at the period when the faction that had begun it for the Duke of Orleans became sensible that he was too much a coward to be the leader of it, and when La Fayette discovered his inability to conduct it, was too far advanced to recede or to stop; and it continued its progress, but in a line that no other revolution had taken, viz. without a military chief, without the intervention of the army, and to gain triumphs, not for any ambitious conspirator, but for political and moral innovations of the most dangerous nature; the most suited to mislead the multitude, incapable of comprehending them, and to let loose all the passions. The more violent combined to destroy every thing; and their fatal coalition gave birth to Jacobinism, that terrible monster till then unknown, and till now not sufficiently unmasked. This monster took upon itself alone to carry on the revolution; it directed, it executed, all the operations of it, all the explosions, all the outrages: it every where appointed the most active leaders, and, as instruments, employed the profligates of every country. Its power far surpassed that which has been attributed to the inquisition, and other fiery tribunals, by those who have spoken of them with the greatest exaggeration. Its centre was at Paris; and its rays, formed by particular clubs in every town, in every little borough, overspread the whole surface of the kingdom. The constant correspondence kept up between those clubs and that of the capital; or, to use their own expression, *des Sociétés populaires affiliées avec la Société mere*—'between the affiliated popular Societies and the parent Society,' was as secret and as speedy as that of free-masons. In a word, the Jacobin clubs had prevailed in causing themselves to be looked up to as the real national representation. Under that pretence, they censured all the authorities in the most imperious manner; and whenever their denunciations, petitions, or addresses, failed to produce an immediate effect, they gained their point by having recourse to insurrection, assassination, and fire. While Jacobinism thus subjected all France to its controul, an immense number of emissaries propagated its doctrines among foreign nations, and prepared new conquests for it.

"The National Assembly, the capital, indeed we may say all France, was divided into three very distinct parties. The most considerable in number, but unhappily the weakest through a deficiency of plan and resolution, was the party purely Royal: it was adverse to every kind of Revolution, and was solely desirous of some improvements, with the reform of abuses and pecuniary privileges:—the most able, and most intriguing, was the Constitutional party, or that which was desirous of giving France a new monarchical constitution, but modified after the manner of the English, or even the American, by a house of representatives. The third party was the most dangerous of all, by its daring spirit, by its power, and by the number of proselytes it daily acquired in all quarters of the kingdom: it comprised the Democrats of every description, from the Jacobin clubs, calling themselves *Friends of the Constitution*, to the anarchs and robbers.

"The Democratic party, which at first was only auxiliary to the Constitutional one, in the end annihilated it, and became itself subdivided into several other parties, whose fatal struggles produced the subsequent revolutions, and may still produce many more. But in principle, the Constitutionalists and the Democrats formed two distinct, though confederate, factions; both were desirous of a revolution, and employed all the usual means of accomplishing it, except troops, which could be of no use to them, for neither of them had a leader to put at the head of the army. But as it was equally of importance to both that [illegible] be deprived of the power of [illegible] they laboured in concert to disorganise [illegible] complete success of that manœuvre was [illegible] ved by the fatal issue of the departure of the royal family for Montmedi. The revolution [illegible] daring and rapid stride, which was [illegible] pretended constitution act of 1791 [illegible] of its principles, and the defects of its [illegible], present a faithful picture of the division of its authors, and of the opposite interests by which they were swayed. It was, properly speaking, a compact between the faction of the Constitutionalists and that of the Democrats, in which they mutually made concessions and sacrifices.

425 Constitution of 1791 completes the first revolution.

"Be that as it may, this absurd constitution, the everlasting source of remorse or sorrow to all who bore part in it, might have been got over without a shock, and led back to the old principles of monarchical government, if the Assembly who framed it had not separated before they witnessed the execution of it; if, in imposing on the king the obligation to maintain it, they had not deprived him of the power and the means; and above all, if the certain consequence of the new mode of proceeding at the elections had not been to secure, in the second Assembly, a considerable majority of the Democratic against the Constitutional party.

"The second Assembly was also divided by three factions, the weakest of which was the one that wished to maintain the constitution. The other two were for a new revolution and a republic; but they differed in this, that the former, composed of the Brissotins and Girondists, was for effecting it gradually, by beginning with divesting the king of popularity, and allowing the public

public mind time to wean itself from its natural attachment to monarchy; and the latter, which was the least numerous, was eager to have the republic established as soon as possible. These two factions, having the same object in view, though taking different roads, were necessarily auxiliaries to each other; and the pamphlets, excitations to commotion, and revolutionary measures of both, equally tended to overthrow the constitution of 1791.

"Those different factions, almost entirely composed of advocates, solicitors, apostate priests, doctors, and a few literary men, having no military chief capable of taking the command of the army, dreaded the troops, who had sworn allegiance to the constitution, and obedience to the king, and who moreover might be influenced by their officers, among whom there still remained some royalists. [illegible]
on t [illegible]
the [illegible]
cessary, [illegible]
council were equally averse. No more was wanting to determine the attack which was directed, almost at the same time, against all the ministers, in order to compel them to retire, and to put the king under the necessity of appointing others more disposed to second the views of the parties. Unhappily this attempt was attended with all the success they had promised themselves; and [illegible] s of the new ministry was to declare [illegible] the same time, the emi- [illegible] and which was almost [illegible] the lowest class of peo- [illegible] of the royal party, [illegible] of [illegible] best defenders, expo- [illegible] and insults that sprang from innu- [illegible] for which the disasters at the be- [illegible] but too many opportu- [illegible]

[illegible] and accelerated the new [illegible] on the 10th of Au- [illegible] nment of the [illegible] tion of the consti- [illegible] 1. The latter, ho[we]ver, was not entirely abandoned on that day; for the project of the Girondists, who had laid the plot of that horrible conspiracy, was then only to declare the king's deposition, in order to place the prince royal upon the throne, under the guidance of a regency composed of their own creatures; but they were hurried away much farther than they meant to go, by the violence with which the most furious of the Jacobins, who took the lead in the insurrection, conducted all their enterprises. The prince royal, instead of being crowned, was shut up in the Temple; and if France at that moment was not declared a republic, it was less owing to any remaining respect for the constitution, than to the fear the legislative body was in of raising the army against it, and also the majority of the nation, who would naturally be angry to see a constitution which seemed to be rendered secure and stable by so many oaths, thus precipitately overthrown, without their having been consulted.

[illegible] revolution.

"It was on these considerations that the opinion was adopted, that a National Convention should be convoked, to determine the fate of royalty. Prompt in seizing all the means that might ensure the success of this second revolution, the Assembly, under pretence of giving every possible latitude to the freedom of elections, decreed, that all its members should be eligible for the National Convention.

French Revolution.

"From that moment the Girondists daily lost ground, and the most flaming members of the Democratic party, supported by the club of Jacobins, by the new Commune of Paris, and by the Tribunes, made themselves masters of every debate. It was of the utmost importance to them to rule the ensuing elections; and this was secured to them by the horrible consternation which the massacres of the 2d of September struck throughout the kingdom. The terror of being assassinated, or at least cruelly treated, drove from all the Primary Assemblies, not only the royalists and constitutionalists, but moderate men of all parties. Of course, these assemblies became entirely composed of the weakest men [illegible]

[illegible] legislative body. Accordingly, this third Assembly, in the first quarter of an hour of their first sitting, were heard shouting their votes for the abolition of royalty, and proclaiming the republic, upon the motion of a member who had formerly been a player.

"Such an opening but too plainly shewed what was to be expected from that horde of plunderers which composed the majority of the National Convention, and of whom Robespierre, Danton, Marat, and the other ringleaders, formed their party. That of the Brissotins and Girondists still existed, and was the only one really republican. These semi-wretches, glutted with the horrors already committed, seemed desirous of arresting the torrent of them, and laboured to introduce into the Assembly the calm and moderati[on] that were necessary to give the new republic a wise and solid organization. But the superiority of their knowledge, talents, and eloquence, which their opponents could not dispute, had no power over tigers thirsting for blood, who neither attended to nor suffered motions but of the blackest tendency. No doubt they had occasion for atrocities upon atrocities to prepare the terror-struck nation to allow them to commit, in its name, the most execrable of all, the murder of the unfortunate Louis XVI: and that martyrdom was necessary to bring about a third revolution, already brewing in the brain of Robespierre. Fear had greatly contributed to the two former: but this was effected by terror alone, without popular tumults, or the intervention of the armies; which, now drawn by their conquests beyond the frontiers, never heard any thing of the revolutions at home, till they were accomplished, and always obeyed the prevailing faction, by whom they were paid.

427 The third revolution.

"By the degree of ferocity discovered by the members of the Convention in passing sentence upon the king, and in the debates relative to the constitution of 1793, Robespierre was enabled to mark which of the deputies were likely to second his views, and which of them it was his part to sacrifice.

"The people could not but with transport receive a constitution which seemed to realise the chimera of its sovereignty, but which would only have given a kind of construction to anarchy, if the execution of this new code had not been suspended under the pretext, belonging in common to all acts of despotism and tyranny, of *the supreme law of the safety of the state.* This suspension

French Revolution

sion was effected, by establishing the Provisionary Government, which, under the title of Revolutionary Government, concentrated all the powers in the National Convention until there was an end to the war and all intestine troubles.

" Although the faction, at the head of which Robespierre was, had a decided majority in the Assembly, and might consequently have considered themselves as really and exclusively exercising the sovereign power, he was a demagogue of too despotic a nature to stomach even the appearance of sharing the empire with so many co-sovereigns. He greatly reduced their number, by causing all the powers invested in the National Assembly by the decrees that had established the revolutionary government, to be transferred to a committee, to which he got himself appointed, and where he was sure of the sole rule, by obtaining for colleagues men less daring than himself, though equally wicked; such as Couthon, St Just, Barrere, and others like them. This committee, who had the assurance to style themselves the *Committee of Public Safety*, very soon seized upon both the legislative and executive powers, and exercised them with the most sanguinary tyranny ever yet heard of. The ministers were merely their clerks; and the subjugated Assembly, without murmur or objection, passed all the revolutionary laws which were proposed, or rather dictated, by them. One of their most horrible and decisive conceptions was that of those Revolutionary Tribunals which covered France with scaffolds, where thousands of victims of every rank, age, and sex, were daily sacrificed; so that no class of men could be free from that stupefying and general terror which Robespierre found it necessary to spread, in order to establish and make his power known. He soon himself dragged some members of his own party, such as Danton, Camille des Moulins, and others, whose energy and popularity had offended him, before one of those tribunals, where he had them condemned to death. By the same means he got rid of the chief leaders among the Brissotines and Girondists; while he caused all the moderate republican party who were still members of the Assembly, except those who had time and address to escape, to be sent to prison, in order to be sentenced and executed on the first occasion.

416 The fourth revolution produces

" In this manner ended the third revolution, in which the people, frozen with terror, did not dare to take a part. Instead of an army of soldiers, Robespierre employed an army of executioners and assassins, set up as revolutionary judges; and the guillotine, striking or menacing all heads indiscriminately, made France, from one end to the other, submit to him, by the means of terror or of death. Thus was this nation, formerly so proud, even to idolatry, of its kings, seen to expiate, by rivers of blood, the crime of having suffered his to be spilt who was the most virtuous of all their monarchs.

" In the room of that famous Bastile, whose celebrated capture and demolition had set only seven prisoners at liberty, two of whom had been long in a state of lunacy, the colleges, the seminaries, and all the religious houses of the kingdom, were converted into so many state prisons, into which were incessantly crowded, from time to time, the victims devoted to feed the ever-working guillotines, which were never suffered to stand still for a day, because they were at once the chief resource of supplies for the government, and the instrument of its ferocity. ' The guillotine coins money for the republic,' was said in the tribune by one of Robespierre's vilest agents *. In fact, according to the jurisprudence of the Revolutionary Tribunals, the rich of every class, being declared suspected persons, received sentence of death, for no other reason than that of giving the confiscation of their property a show of judicial form.

French Revolution

* Barrere.

" Still blood flowed too slowly to satisfy Robespierre; his aim was but partly attained by the proscription of the nobles, the priests, and the wealthy. He fancied, not only an aristocracy of talents and knowledge, but of the virtues, none of which would his trusty orators and journalists admit, save that horrid *patriotism* which was estimated according to the enormity of the crimes committed in favour of the revolution. His plan was to reduce the French people to a mere plantation of slaves, too ignorant, too stupid, or too pusillanimous, to conceive the idea of breaking the chains with which he would have loaded them in the name of liberty; and he might have succeeded in it, had not his ambition, as impatient as it was jealous, too soon unveiled the intention of resorting to the guillotine to strike off the shackles with which an assembly of representatives of the nation fettered, or might fetter, his power. He was about to give this decisive blow, which he had concerted with the Commune of Paris, the Revolutionary Tribunal, the Club of [illegible] cers of the Natio[illegible] Convention, who [illegible] sced, anticipated [illegible] pected it, by attacking [illegible] energy sufficient to rouse all [illegible] against him and against the Jacobins [illegible] blows, and victory remained [illegible] but at length declared against Robespierre [illegible] of a day, that execrable monster was [illegible] highest pitch of power [illegible] the very scaffold that [illegible] of his last victims. [illegible] Committee of Public Safety [illegible] National Guard, in [illegible] many of his agents in the provinces, met the same fate. The Revolutionary Tribunals were suppressed, and the prisons thrown open to all whom they had cast into them.

427 The constitution of 1795.

" This fourth revolution, in which the faction then esteemed the moderate party overthrew the terrorists, and seized the supreme power, was no less complete than those which had preceded it, and produced the constitution of 1795. All France received as a great blessing a constitution that delivered them from the revolutionary government and its infernal policy. Besides, it had, in spite of great defects, the merit of coming nearer than the two preceding ones, to the principles of order, of justice, and real liberty; the violation of which had, for five years before, been the source of so many disasters and so many crimes. The royalists, considering it as a step towards monarchy, were unfortunately so imprudent as to triumph in it; and their joy, as premature as indiscreet, alarmed the Assembly to such a degree, that they passed the famous law, ordaining the Primary Assemblies to return two-thirds of the members of the Convention to the legislative body, which

French Revolution. was to succeed that assembly. It was thus that the spirit of the Convention continued, for the first year, to be displayed in the two councils.

"In the year following, the bias of the public mind, perhaps too hastily turned towards royalty, shewed itself in the elections of the members for the new third, so clearly as to alarm the regicides who composed the Directory, and the Conventionalists, who still made a third of the legislative body; nor did they lose a moment in devising means for their defence. That which appeared the surest to them was, to publish notices of plots among the royalists, and annex one or more denunciations, in terms so vague as to leave room for implicating, when necessary, all their adversaries; while by the help of this imposture they procured some secret information, artfully fabricated, and ever easily obtained through threats or rewards by those who have at command the guillotine and the public treasure.

"This masked battery was ready to be opened before the members of the new third took their seats. These at first confined themselves to the securing of a constant majority in the two councils in favour of the moderate opinions; but in a little time every sitting was marked by the repeal of some revolutionary law, or by some decree tending to restrain the executive authority within the limits fixed by the constitution.

428 The fifth revolution. "The Directory [illegible] of their power, and dreading [illegible] attacks upon it, came to a [illegible] postponing the blow they [illegible] the legislative assembly [illegible] in it [illegible] as any of those [illegible] It differed indeed from [illegible] facility and promptness with [illegible] although the party which pre- [illegible] the majority of the Directory, and [illegible] Legislative Body, had to combat [illegible] but against the opi- [illegible] of the public. [illegible] majority of the two [illegible] vanish- ed [illegible] force of a detach- [illegible] hundred men; [illegible] that the power of the public opinion, ridiculously exaggerated in these days, is and can be no more, under a firm and well ordered government, than a mere fancy. Men accustom themselves too easily to take for public opinion the private opinions made public by certain writers, whose caution or audaciousness depends always upon the energy or feebleness of the supreme authority. It is the same thing with popular commotions: they are easily excited under a weak government, which does not possess the wisdom to prevent or the spirit to suppress them; but a vigorous, just, and strict government has nothing to fear from them. The Directory, compelled to withdraw the larger body of troops, which they had thought necessary to ensure the revolution they were meditating, discovered, no doubt, great ability in securing the two councils, by appearing to dread them: but it was chiefly to the energy of their measures, and to the concentration and promptness with which they were executed, that they owed their success. Two days before, the legislative body might, without obstruction, have impeached, arrested, and even outlawed, the majority of the Directory, who were execrated by the public under the title of Triumvirate; and, if requisite, they would have been supported by more than 30,000 armed citizens, who, with Pichegru and Villot at their head, would soon have dispersed, and perhaps brought over, the feeble detachments of troops of the line which the Directory had at their command. The legislative body, relying too much upon its popularity, did not sufficiently consider, that the people, whose impetuosity is commonly decisive when allowed to take advantage in attack, are always feeble on the defensive, and totally unable to withstand every assault made previous to an insurrection, for it is always easy to prevent their assembling. It was on this principle that the Directory founded their operations, and the 5th of September too well proves how justly. That day reduced the legislative body, by the most degrading subjugation, to a mere disgusting caricature of national representation; it invested the Directory with the most arbitrary and tyrannic power, and restored the system of Robespierre, under a form less bloody, but not less pernicious; for the Revolutionary Tribunals which that monster had established, were scarcely more expeditious than the military ones of the Directory. The power of arbitrary and unlimited transportation is, in time, as destructive as the guillotine, without possessing, like that, the advantage of exciting a salutary horror, which, by recovering the people from the state of stupor and apathy, the constant effects of terror, gives them both recollection and force to break their chains. Though, in violating the most essential regulations of the constitution, the Directory obtained a temporary confirmation of their power, their example pointed out to Bonaparte and Sieyes the path which they pursued with infinite address, and in which they accomplished a sixth revolution." 429 The sixth revolution, and consular government.

How long the consular government will continue, it is impossible to conjecture; but we may, without presumption, venture to predict, that it cannot be permanent. To the Jacobins and original constitutionalists it must be more obnoxious than the old government; because Bonaparte is more despotic than was Louis XIV; and the royalists, though they may prefer the vigorous and comparatively mild government of one man, whose talents are indisputable, to the ferocious tyranny of the lowest of the rabble, must look with indignation at a foreign adventurer seated on the throne of their ancient monarchy.

RHABDOLOGY, or Rabdology, in arithmetic, a name given by Napier to a method of performing some of the more difficult operations of numbers by means of certain square little rods. Upon these are inscribed the simple numbers; then by shifting them according to certain rules, those operations are performed by simply adding or subtracting the numbers as they stand upon the rods. See Napier's *Rabdologia*, printed in 1617. See also the article Napier's *Bones*.

RHOMB Solid, consists of two equal and right cones joined together at their bases.

RICE (see that article, and Oryza, *Encycl.*) is strongly recommended, in a late publication, as the best corrective of *sprit* flour, of which there is a great quantity in Scotland every year, and of course a great deal of unpleasant and unwholesome bread. The gentleman, who writes the short paper alluded to, directs ten pounds of flour and one pound of ground rice, with the usual

usual quantity of yest, to be placed, for about two hours, before a fire, and then formed into bread in the common way. This addition of rice, besides correcting the bad qualities of the damaged flour, adds, he says, much to its nutriment: and he is undoubtedly right; for the flour of rice, though very nutritious, is so dry, that it is difficult to make bread of it by itself. See *Bread of Rice*, in this *Suppl.*

As rice is a favourite substitute for bread in years of scarcity, it may not be disagreeable to our readers to know the method of cultivating the plant in those countries where it is the principal food of the inhabitants. We have the following full and perspicuous account of the Chinese practice by Sir George Staunton.

"Much of the low grounds in the middle and southern provinces of the empire are appropriated to the culture of that grain. It constitutes, in fact, the principal part of the food of all those inhabitants, who are not so indigent as to be forced to subsist on other and cheaper kinds of grain. A great proportion of the surface of the country is well adapted for the production of rice, which, from the time the seed is committed to the soil till the plant approaches to maturity, requires to be immersed in a sheet of water. Many and great rivers run through the several provinces of China, the low grounds bordering on those rivers are annually inundated, by which means is brought upon their surface rich mud or mucilage that fertilizes the soil, in the same manner as Egypt receives its fecundative quality from the overflowing of the Nile. The periodical rains which fall near the sources of the Yellow and the Kiang rivers, not very far distant from those of the Ganges and the Burumpooter, among the mountains bounding India to the north, and China to the west, often swell those rivers to a prodigious height, though not a drop of rain should have fallen on the plains through which they afterwards flow.

"After the mud has lain some days upon the plains in China, preparations are made for planting them with rice. For this purpose, a small spot of ground is inclosed by a bank of clay; the earth is ploughed up; and an upright harrow, with a row of wooden pins in the lower end, is drawn lightly over it by a buffalo. The grain, which had previously been steeped in dung diluted with animal water, is then sown very thickly on it. A thin sheet of water is immediately brought over it, either by channels leading to the spot from a source above it, or when below it by means of a chain pump, of which the use is as familiar as that of a hoe to every Chinese husbandman. In a few days the shoots appear above the water. In that interval, the remainder of the ground intended for cultivation, if stiff, is ploughed, the lumps broken by hoes, and the surface levelled by the harrow. As soon as the shoots have attained the height of six or seven inches, they are plucked up by the roots, the tops of the blades cut off, and each root is planted separately, sometimes in small furrows turned with the plough, and sometimes in holes made in rows by a drilling stick for that purpose. The roots are about half a foot asunder. Water is brought over them a second time. For the convenience of irrigation, and to regulate its proportion, the rice fields are subdivided by narrow ridges of clay, into small inclosures. Through a channel, in each ridge, the water is conveyed at will to every subdivision of the field. As the rice approaches to maturity, the water, by evaporation and absorption, disappears entirely; and the crop, when ripe, covers dry ground. The first crop or harvest, in the southern provinces particularly, happens towards the end of May or beginning of June. The instrument for reaping is a small sickle, dentated like a saw, and crooked. Neither carts nor cattle are used to carry the sheaves off from the spot where they were reaped; but they are placed regularly in frames, two of which, suspended at the extremities of a bamboo pole, are carried across the shoulders of a man, to the place intended for disengaging the grain from the stems which had supported it. This operation is performed, not only by a flail, as is customary in Europe, or by cattle treading the corn in the manner of other Orientalists, but sometimes also by striking it against a plank set upon its edge, or beating it against the side of a large tub scolloped for that purpose; the back and sides being much higher than the front, to prevent the grain from being dispersed. After being winnowed, it is carried to the granary.

"To remove the skin or husk of rice, a large strong earthen vessel, or hollow stone, in form somewhat like that which is used elsewhere for filtering water, is fixed firmly in the ground, and the grain, placed in it, is struck with a conical stone fixed to the extremity of a lever, [illegible] indeed imperfectly, the husk, [illegible] by a person treading u[illegible] object is attained [illegible] two flat stones of [illegible] round upo[illegible] not to break the [illegible] formed on a larger [illegible] axis of the wheel carrying [illegible] king upon the [illegible] of levers [illegible] manner [illegible] done by [illegible] twenty [illegible] levers [illegible] from which [illegible] into chaff to serve [illegible] employed [illegible]

"The [illegible] hour [illegible] ground is [illegible] of fresh seeds. [illegible] is that of pulling up [illegible] small heaps, which are [illegible] upon the field. The former processes are afterwards renewed. The second crop is generally ripe late in October or early in November. The grain is treated as before; but the stubble is no longer burnt. It is turned under with the plough, and left to putrefy in the earth. This, with the slime brought upon the ground by inundation, are the only manures usually employed in the culture of rice."

RIDEAU, in fortification, a small elevation of earth, extending itself lengthwise on a plain; serving to cover a camp, or give an advantage to a post.

Rideau is sometimes also used for a trench, the earth of which is thrown up on its side, to serve as a parapet for covering the men.

RIDLEY (Dr Gloster), was of the same family with Dr Nicolas Ridley, Bishop of London, and Martyr to the Reformation. (See Ridley, *Encycl.*) He was born at sea, in 1702, on board the Gloucester East Indiaman; to which circumstance he was indebted for his

his Christian name. He received his education at Winchester school, and thence was elected to a fellowship at New college, Oxford, where he proceeded B. C. L. April 29. 1729. In those two seminaries he cultivated an early acquaintance with the muses, and laid the foundation of those elegant and solid acquirements for which he was afterwards so eminently distinguished as a poet, an historian, and a divine. During a vacancy in 1728, he joined with four friends, viz. Mr Thomas Fletcher (afterwards Bishop of Kildare), Mr (afterwards Dr) Eyre, Mr Morrison, and Mr Jennens, in writing a tragedy called "The Fruitless Redress," each undertaking an act on a plan previously concerted. When they delivered in their several proportions at their meeting in the winter, few readers would have known that the whole was not the production of a single hand. This tragedy, which was offered to Mr Wilks, but never acted, is still in MS. with another called "Jugurtha." Dr Ridley in his youth was much addicted to theatrical performances. Midhurst, in Sussex, was the place where they were exhibited; and the company of gentlemen actors to which he belonged consisted chiefly of his coadjutors in the tragedy already mentioned. He is said to have performed the characters of Marc Antony, Jaffier, Horatio, and Moneses, with distinguished applause; a circumstance that will be readily believed by those who are no [illegible] to his judicious and graceful [illegible]

For [illegible] preferment than [illegible] in Norfolk, and [illegible] where he resided. [illegible] after, the dona[illegible] Between these two places [illegible] (as he expressed it) rolled for [illegible] upon postchaise wheels, [illegible] time for even the proper studies of [illegible] ones of his profession." Yet [illegible] possession of, [illegible] and was honour[illegible] who were not [illegible] for worth.

In [illegible] "Eight Sermons at Lady Moyer's Lectures," which were published in 1742, 8vo. In 1756 he declined an offer of going to Ireland as first chaplain to the Duke of Bedford; in return for which he was to have had the choice of promotion, ther at Christ-church, Canterbury, Westminster, Windsor. His modesty inducing him to leave choice of these to his patron, the consequence was, he obtained none of them. In 1763, he published "Life of Bishop Ridley," in 4to, by subscription, and cleared by it as much as brought him 800l. in the public funds. In the latter part of his life he had the misfortune to lose both his sons, each of them a youth of abilities. The elder, James, was author of "The Tales of the Genii," and some other literary performances. Thomas, the younger, was sent by the East India Company as a writer to Madras, where he was no sooner settled than he died of the small-pox. In 1765, Dr Ridley published his "Review of Philips's Life of Cardinal Pole;" and in 1768, in reward for his labours in this controversy, and in another which "The Confessional" produced, he was presented by Archbishop Secker to a golden prebend in the cathedral church of Salisbury (an option), the only reward he received from the great during a long, useful, and laborious life, devoted to the duties of his function. At length, worn out with infirmities, he departed this life in 1774, leaving a widow and four daughters. His epitaph, which was written by Bishop Lowth with his usual elegance, informs us, that for his merits the university of Oxford conferred upon him the degree of D. D. by diploma, which is the highest literary honour which that learned body has to bestow.

Rienzi.

RIENZI (Nicolas Gabrini de), one of the most extraordinary men of the 14th century, was born at Rome, we know not in what year. His father, Lawrence Gabrini, was a mean vintner, or, as others say, a miller, and his mother a laundress. These persons, however, found the means of giving their son a liberal education; and to a good natural understanding he joined an uncommon assiduity, and made great proficiency in ancient literature. Every thing which he read he compared with similar passages that occurred within his own observation; whence he made reflections, by which he regulated his conduct. To this he added a great knowledge in the laws and customs of nations. He had a vast memory: he retained much of Cicero, Valerius Maximus, Livy, the two Senecas, and Cæsar's Commentaries especially, which he read continually, and often quoted by application to the events of his own times. This fund of learning proved the basis and foundation of his rise. The desire he had to distinguish himself in the knowledge of monumental history, drew him to another sort of science, in which few men at that time exerted themselves. He passed whole days among the inscriptions which are to be found at Rome, and acquired soon the reputation of a great antiquary. Having hence formed within himself the most exalted notions of the justice, liberty, and ancient grandeur of the old Romans, words he was perpetually repeating to the people, he at length persuaded not only himself, but the giddy mob his followers, that he should one day become the restorer of the Roman republic. His advantageous stature, his countenance, and that air of importance which he well knew how to assume, deeply imprinted all that he said in the minds of his audience.

Nor was it only by the populace that he was admired; he also found means to insinuate himself into the favour of those who partook of the administration. Rienzi's talents procured him to be nominated one of the deputies sent by the Romans to Pope Clement VI. who resided at Avignon. The intention of this deputation was to make his Holiness sensible, how prejudicial his absence was, as well to himself as to the interest of Rome. At his first audience, our hero charmed the court of Avignon by his eloquence and the sprightliness of his conversation. Encouraged by success, he one day took the liberty to tell the Pope, that the grandees of Rome were avowed robbers, public thieves, infamous adulterers, and illustrious profligates; who, by their example, authorised the most horrid crimes. To them he attributed the desolation of Rome; of which he drew so lively a picture, that the Holy Father was moved, and exceedingly incensed against the Roman nobility. Cardinal Colonna, in other respects a lover of real merit, could not help considering these reproaches as reflecting upon some of his family; and therefore found means of disgracing Rienzi, so that he

fell into extreme misery, vexation, and sickness, which, joined with indigence, brought him to an hospital. Nevertheless, the same hand that threw him down, raised him up again. The cardinal, who was all compassion, caused him to appear before the Pope, in assurance of his being a good man, and a great partizan for justice and equity. The Pope approved of him more than ever; and, to give him proofs of his esteem and confidence, made him apostolic notary, and sent him back loaded with favours.

Being returned to Rome, he began to execute the functions of his office; and by affability, candour, assiduity, and impartiality, in the administration of justice, he arrived at a superior degree of popularity; which he still improved by continued invectives against the vices of the great, whom he took care to render as odious as possible; till at last, for some ill-timed freedoms of speech, he was not only severely reprimanded, but displaced. From this time it was his constant endeavour to inspire the people with a fondness for their ancient liberties; to which purpose he caused to be hung up in the most public places emblematic pictures, expressive of the former splendour and present decline of Rome. To these he added frequent harangues and predictions upon the same subject. In this manner he proceeded till one party looked on him only as a madman, while others caressed him as their protector. At length he ventured to open himself to such as he believed male contents. At first he took them separately; afterwards, when he thought he had firmly attached a sufficient number to his interest, he assembled them together, and represented to them the deplorable state of the city, over run with debaucheries, and the incapacities of their governors to correct or amend them. As a necessary foundation for the enterprise, he gave them an insight into the immense revenues of the apostolic chamber: He demonstrated, that the Pope could, only at the rate of fourpence, raise a hundred thousand florins by firing, as much by salt, and as much more by the customs and others duties. As for the rest, said he, I would not have you imagine that it is without the Pope's consent I lay hands on the revenues. Alas! how many others in this city plunder the effects of the church contrary to his will!

By this artful lie, he so animated his auditors, that they declared they would make no scruple of securing these treasures for whatever end might be most convenient; and that they were devoted to the will of him their chief. Having obtained so much, to secure his adherents from a revolt, he tendered them a paper, superscribed, "an *oath* to procure the good establishment;" and made them subscribe and swear to it before he dismissed them. By what means he prevailed on the Pope's vicar to give a tacit sanction to his project, is not certainly known; that he did procure that sanction, and that it was looked on as a masterpiece of policy, is generally admitted. "The 20th of May, being Whitsunday, he fixed upon to sanctify in some sort his enterprise; and pretended, that all he acted was by particular inspiration of the Holy Ghost. About nine, he came out of the church bare-headed, accompanied by the Pope's vicar, surrounded by an hundred armed men. A vast crowd followed him with shouts and acclamations." The gentlemen conspirators carried three standards before him, on which were wrought devices, insinuating, that his design was to re-establish liberty, justice, and peace. In this manner he proceeded directly to the Capitol, where he mounted the rostrum; and, with more boldness and energy than ever, expatiated on the miseries to which the Romans were reduced: at the same time telling them, without hesitation, "that the happy hour of their deliverance was at length come, and that he was to be their deliverer, regardless of the dangers he was exposed to for the service of the Holy Father and the people's safety." After which, he ordered the laws of what he called the good establishment to be read: "assured that the Romans would resolve to observe these laws, he engaged in a short time to re-establish them in their ancient grandeur."

The laws of the good establishment promised plenty and security, which were greatly wanted; and the humiliation of the nobility, who were deemed common oppressors. Such laws could not fail of being agreeable to a people who found in them these double advantages; wherefore, "enraptured with the pleasing ideas of a liberty to which they were at present strangers, and the hope of gain, they came most zealously into the fanaticism of Rienzi. They resumed the pretended authority of the Romans; they declared him sovereign [illegible] power of life and [illegible] and repealing [illegible] a word, [illegible] over all the [illegible] Rienzi [illegible] willing to [illegible] tions, the [illegible] vicar (the Bishop [illegible] cond, that the Pope [illegible] which (he told them) [illegible] tain. [illegible] one [illegible] thus [illegible] the other [illegible] would [illegible] graced [illegible] he possessed [illegible] Bishop [illegible] prises. [illegible] an idol, to [illegible] dismissed [illegible] and hope. He seized upon the palace, where he continued after he had turned out the senators; and, the same day, he began to dictate his laws in the Capitol." This election, though not very pleasing to the Pope, was ratified by him; nevertheless, Rienzi meditated the obtaining of a title, exclusive of the papal prerogative. Well versed in the Roman history, he was no stranger to the extent of the tribunitial authority; and as he owed his elevation to the people, he chose to have the title of their magistrate. He asked it, and it was conferred on him and his copartner, with the addition of deliverers of their country. Our adventurer's behaviour in his elevation was at first such as commanded esteem and respect, not only from the Romans, but from all the neighbouring states. But it is difficult for a person of mean birth, elevated at once, by the caprice of fortune, to the most exalted station, to move rightly in a sphere wherein he must breathe an air he has been unaccustomed to. Rienzi ascended by degrees the summit of his fortune.

Rienzi. Riches softened, power dazzled, the pomp of his cavalcades animated, and formed in his mind ideas adequate to those of princes born to empire. Hence luxury invaded his table, and tyranny took possession of his heart. The Pope conceived his designs to be contrary to the interests of the holy see; and the nobles, whose power it had been his constant endeavours to depress, conspired against him: they succeeded; and Rienzi was forced to quit an authority he had possessed little more than six months. It was to a precipitate flight that he was indebted, at this juncture, for his life; and to different disguises for his subsequent preservation.

Having made an ineffectual effort at Rome, and "not knowing where to find a new resource to carry on his designs, he took a most bold step, conformable to that rashness which had so often assisted him in his former exploits. He determined to go to Prague, to Charles king of the Romans, whom the year before he had summoned to his tribunal," and who, he foresaw, would deliver him up to a Pope highly incensed against him. He was accordingly soon after sent to Avignon, and there thrown into a prison, where he continued three years. The divisions and disturbances in Italy, occasioned by the number of petty tyrants that had established themselves [illegible] territories, and even at Rome, [illegible] Innocent VI. who [illegible] sensible that the Romans [illegible] our hero, [illegible] teach him to [illegible] formerly done [illegible] for [illegible] inviolable at[illegible] should be [illegible] instrument to [illegible] other tyrants; and [illegible] his liberty, but also ap[illegible] of [illegible] He met [illegible] newly [illegible] resolu[illegible] his [illegible] inclined [illegible] against him, that he [illegible]

"Such was the [illegible] one of the most renowned [illegible] forming a conspiracy full of extravagance, and executing it in the sight of almost the whole world, with such success that he became sovereign of Rome; after causing plenty, justice, and liberty, to flourish among the Romans; after protecting potentates, and terrifying sovereign princes; after being arbiter of crowned heads; after reestablishing the ancient majesty and power of the Roman republic, and filling all Europe with his fame during the seven months of his first reign; after having compelled his masters themselves to confirm him in the authority he had usurped against their interests—fell at length at the end of his second, which lasted not four months, a sacrifice to the nobility, whose ruin he had vowed, and to those vast projects which his death prevented him from putting into execution*."

If the reader perceive any thing similar at present to the rise of this wonderful man to sovereign authority, he may perhaps console himself with the hope that the modern consul will in all probability fall like the modern tribune. Both rose by displays of the most daring courage; the associates of both were priests, who in the actual exercise of government were cyphers; both promised liberty and plenty to the people whom they ruled with absolute sway; and both have trampled upon the order of nobility.

* Biog. Dict. new edit.

Ring || Rodney.

RING, in astronomy and navigation, an instrument used for taking the sun's altitude, &c. It is usually of brass, about nine inches diameter, suspended by a little swivel, at the distance of 45° from the point of which is a perforation, which is the centre of a quadrant of 90° divided in the inner concave surface. To use it, let it be held up by the swivel, and turned round to the sun, till his rays, falling through the hole, make a spot among the degrees, which marks the altitude required. This instrument is preferred before the astrolabe, because the divisions are here larger than on that instrument.

ROBERVALLIAN LINES, a name given to certain lines used for the transformation of figures; thus called from their inventor Roberval, an eminent French mathematician, who died in 1675, aged 76 years. These lines bound spaces that are infinitely extended in length, which are nevertheless equal to other spaces that are terminated on all sides.

The Abbot Gallois, in the Memoirs of the Royal Academy, anno 1693, observes, that the method of transforming figures, explained at the latter end of Roberval's Treatise of Indivisibles, was the same with that afterwards published by James Gregory, in his *Geometria Universalis*, and also by Barrow in his *Lectiones Geometricæ*; and that, by a letter of Torricelli, it appears, that Roberval was the inventor of this manner of transforming figures, by means of certain lines, which Torricelli therefore called *Robervallian lines*. He adds, that it is highly probable that J. Gregory first learned the method in the journey he made to Padua in 1668, the method itself having been known in Italy from the year 1646, though the book was not published till the year 1692.

This account has been, we think, completely refuted by David Gregory in his vindication of his uncle, published in the Philosophical Transactions of 1694. The Abbot, however, rejoined in the Memoirs of the French Academy of 1703; and it is but fair to observe, that Dr Hutton, speaking of the controversy, expresses himself as if he thought it undecided.

RODNEY (Lord). In our short sketch of the life of that gallant officer (*Encycl.*), we mentioned with regret our not having heard of any monument being erected to his honour in his native country. We have since learned that there is a pillar upon the Brythen in Shropshire, which was erected to his memory long before the publication of our article.

Having this great man again under our notice, we insert with pleasure the following extract of a letter, which we received from an obliging correspondent soon after the publication of the volume which contains our biographical sketch of the Admiral: "Whatever were Rodney's merits as a naval commander (says our correspondent), there is a more brilliant part of his character which you have entirely neglected. Prior to his success against the Spanish Admiral Don Langara, the English who had the misfortune to become prisoners of war to the Spaniards, were treated with the greatest inhumanity, and it required more than a common

ftrength of conftitution to exift for any length of time in a Spanifh prifon. When the Spanifh admiral fell into the hands of Rodney, he, his officers and feamen, expected to meet with the fame treatment they had always inflicted, and which they would have inflicted on Rodney, his officers, and feamen, had the Spaniards been the victors; but, to their furprife, they found in Admiral Rodney (and, of courfe, in all that were under his command) a man who fympathifed in their misfortune, who miniftered to their neceffities, and, by a humane and polite behaviour to his prifoners, made an impreffion on the minds of the Spaniards, which could not but have its effect in mitigating the fufferings of the Englifh in Spanifh prifons: but he did not ftop here; he took an opportunity, when their minds were expanded by gratitude (and in a ftate to receive the full force of fuch a reprefentation), to reprefent to them the miferable condition of his countrymen who were prifoners in Spain, and obtained a promife (which, I believe, was punctually performed), that Englifhmen, when prifoners in Spain, fhould be made as comfortable as their fituation would admit of. This was a piece of fervice to his country which furely merits to be recorded, and which will exalt him as much in the opinion of good men as the moft brilliant difplay of *courage*, which is a quality as frequently difcovered in the favage as in the cultivated mind."

ROEBUCK (John, M D.), was born at Sheffield in Yorkfhire in the year 1718. His father was a confiderable manufacturer and exporter of Sheffield goods, who by his abilities and induftry had acquired a competent fortune. John, his eldeft fon, the fubject of this memoir, was intended by his father for carrying on his own lucrative bufinefs at Sheffield; but was, from his early youth, irrefiftibly attached to other purfuits, more calculated to gratify his ambition, and give fuller play to his powers. Notwithftanding this difappointment in his favourite object, his father had liberality enough to encourage his rifing genius, and to give him all the advantages of a regular education.

After he had gone through the ufual courfe of the grammar fchool at Sheffield, both his father and mother being ftrict diffenters, they placed their fon for fome years under the tuition of the late Dr Doddridge, who was at that time mafter of an academy at Northampton, and had juftly acquired high reputation among the diffenters, both as a divine and as an inftructor of youth. Under the Doctor's care Mr Roebuck made great proficiency, and laid the foundation of that claffical tafte and knowledge for which he was afterwards eminently diftinguifhed. It would appear that Dr Doddridge had been much pleafed with the ardour and enthufiafm, in the purfuit of knowledge, difcovered by his pupil; for Mr Roebuck, in an after period of his life, ufed frequently to mention the fubjects of converfation and inquiries of various kinds, in which the Doctor had engaged him. It was during his refidence at this academy that he contracted an intimate acquaintance with his fellow-ftudents, Mr Jeremiah Dyfon, afterwards much known in the political world, and Mr Mark Akenfide, afterwards Dr Akenfide, which terminated only with their lives.

From the academy at Northampton he was fent to the univerfity of Edinburgh, where he applied to the ftudy of medicine, and particularly to that of chemiftry, which about that time began to attract fome attention in Scotland. While he refided there, he diftinguifhed himfelf much among his fellow-ftudents in their literary focieties and converfations, by great logical and metaphyfical acutenefs, and by great ingenuity and refource in argumentation. The late fagacious Dr Porterfield, to whom he had been introduced, obferved and encouraged his rifing genius, and was greatly inftrumental in promoting his improvement. There, too, he formed an intimate acquaintance with Mr Hume, Mr Robertfon, afterwards Dr Robertfon, Mr Pringle, afterwards Lord Alemoor, and feveral other perfons of literary eminence; a circumftance which produced in his mind a partiality ever afterwards in favour of Scotland, and contributed not a little to his making choice of it for the chief field of his future exertions and induftry.

After Mr Roebuck had gone through a regular courfe of medical education at Edinburgh, being now determined to follow the practice of phyfic, he next fpent fome time at the univerfity of Leyden, then in high reputation as the firft fchool of medicine in Europe. There, after the ufual refidence and courfe of trials, he obtained a degree in medicine; and his diploma, dated 21ft February 1743, has affixed to it the refpectable names of Mufchenbroek, Ofterdyk, Van Royen, Albinus, Gaubius, &c. He left Leyden, after having vifited fome part of the north of Germany, about the end of the year [illegible].

Soon after his return from the continent, fome circumftances induced Dr Roebuck to fettle as a phyfician at Birmingham. Before that time Birmingham had begun to make a rapid progrefs in its manufactures, and population; and by the death of a noted phyfician, an opening was prefented to him which afforded an immediate profpect of encouragement in that line. His education, talents, and interefting manners were well calculated to promote his fuccefs as a phyfician. He accordingly met there, at a period more early than he expected, with great encouragement; and was foon diftinguifhed, in that town and the country adjacent, for his fkill, integrity, and humane compaffion, in the difcharge of the duties of his profeffion.

It appeared, however, foon after his refidence was fixed at Birmingham, that his ftudies and induftry were turned to various objects befides thofe of his profeffion. Strongly attached to the rifing fcience of chemiftry, he conceived high views of extending its ufefulnefs, and of rendering it fubfervient to the improvement of arts and manufactures. With this view, he fitted up a fmall laboratory in his own houfe, in which he fpent every moment of his time which he could fpare from the duties of his profeffion. There, in the true fpirit of his great mafter Lord Bacon, of whofe philofophy he was an ardent admirer, he carried on various chemical proceffes of great importance, and laid the foundation of his future projects on well-tried and well digefted experiments.

The firft efforts of his genius and induftry, thus directed, led him to the difcovery of certain improved methods of refining gold and filver, and particularly to an ingenious method of collecting the fmaller particles of thefe precious metals, which had been formerly loft in the practical operations of many of the manufacturers. By other chemical proceffes, carried on about the fame time in his little laboratory, he difcovered alfo improved methods of making fublimate, hartfhorn, and

fundry

Roebuck sundry other articles of equal importance. After having received full satisfaction from the experiments upon which such discoveries and improvement were founded, he next digested a plan for rendering them beneficial to himself, and useful to the public. A great part of his time being still employed in the duties of his profession, he found it necessary to connect himself with some person in whom he could repose confidence, and who might be, in other respects, qualified to give him support and assistance in carrying on his intended establishments. With this view, he chose as his associate Mr Samuel Garbet of Birmingham; a gentleman well qualified, by his abilities, activity, and enterprising spirit, for bearing his part in their future undertakings. Their first project was the establishment of an extensive laboratory at Birmingham, for the purposes above mentioned; which, conducted by Dr Roebuck's chemical knowledge, and Mr Garbet's able and judicious management, was productive of many advantages to the manufacturers of that place, and of such emolument to themselves, as contributed greatly to the boldness of their future projects. That laboratory has, ever since that time, continued at Birmingham, and is still conducted by Mr Garbet. Dr Roebuck, long before his death, had given up his interest in it.

About this time, in 1747, the Doctor married Miss Ann Roe of [illegible] spirit, whose [illegible] for enjoying [illegible] their early life, [illegible] anxieties [illegible] but did [illegible] of their lives.

[illegible] perseverance in his chemical [illegible] with the success that attended them, [illegible] step, to other researches of great public [illegible] benefit.

[illegible] of the vitriolic [illegible] acid in [illegible] application to some of [illegible] for that [illegible] various [illegible] had obtained a patent [illegible] though the substances from which it might be obtained, as well as certain methods of obtaining it, had been known to others, and particularly pointed out by Lemery the Elder, and by Glauber, yet Dr Ward was the first, it is believed, who established a profitable manufacture upon the discovery. Much, however, was wanting to render the acid of universal use in chemistry, and of extensive utility in the arts, where great quantities of it were required. The price of it was high, arising from the great expence of the glass vessels, which were made use of by Dr Ward in procuring it, and the frequent accidents to which they were liable in the process.

Dr Roebuck had been for some time engaged in making experiments with a view to reduce the price, and at length discovered a method of preparing it, by substituting, in place of the glass vessels formerly used, lead ones of a great size; which substitution, together with sundry other improvements in different parts of the process, completely effected his end.

After the necessary preparations had been made, Messrs Roebuck and Garbet established a manufacture of the oil of vitriol at Prestonpans, in Scotland, in the year 1749. This establishment not a little alarmed Dr Ward, who attempted to defeat their plan, by taking out a patent for Scotland, in addition to the one he had formerly obtained. In this attempt he failed. Dr Roebuck's discovery was found not to come within the specification of Dr Ward's patent.

The Prestonpans company, convinced that patents are of little avail in preserving the property of new inventions or discoveries, in conducting their vitriol works resolved to have recourse to the more effectual methods of concealment and secrecy. By that method they were enabled to preserve the advantages of their ingenuity and industry for a long period of years, and not only served the public at a much cheaper rate than had ever been done formerly, but, it is believed, they realized, in that manufacture, a greater annual profit from a smaller capital than had been done in any similar undertaking. The vitriol work is still carried on at Prestonpans; but long before Dr Roebuck's death, he was obliged to withdraw his capital from it.

About this time Dr Roebuck was urged, by some of his friends, to leave Birmingham, and to settle as a physician in London, where his abilities might have had a more extensive field of exertion. He had been early honoured with the acquaintance of the late Marquis of Rockingham, who, as a lover of arts, had frequently engaged him in chemical experiments at Rockingham-house. It was there, also, he became acquainted with the late Sir George Saville, and with several other persons of rank and influence. His old friend and schoolfellow Mr Dyson, too, by this time, had acquired considerable name and influence, and pressed him much to take that step. Under such patronage, and with the energy of such talents as Dr Roebuck possessed, there could be little doubt of his soon arriving at an eminent rank as a physician in London. But the chemical concerns, with which he was at that time deeply occupied, holding out to him a prospect of a richer harvest, determined him to give up the practice of medicine altogether, and to fix his residence for the greatest part of the year in Scotland.

The success of the establishment at Prestonpans, which had far exceeded their expectation, enabled the Doctor and his partner Mr Garbet to plan and execute other works of still greater benefit and public utility. In the prosecution of his chemical studies and experiments, Dr Roebuck had been led to bestow great attention on the processes of smelting iron-stone, and had made some discoveries, by which that operation might be greatly facilitated, particularly by using pit-coal in place of charcoal. Mr William Caddell of Cockenzie, in the neighbourhood of Prestonpans, a gentleman earnestly intent upon promoting manufactures in Scotland, had, for several years, laboured, without much success, in establishing a manufacture of iron; a circumstance which may have probably contributed to turn Dr Roebuck's attention more particularly to that subject. As the capital which he and his partner Mr Garbet could appropriate for carrying on the iron manufacture was not equal to such an undertaking, and chiefly depended upon the profits of their other works, their first intention was to attempt a small establishment of that kind in the vicinity of their vitriol works at Prestonpans. But the flattering prospects of success, arising from a course of experiments which Dr Roebuck had lately made, encouraged them to extend their plan,

Roebuck.

plan, and to project a very extensive manufactory of iron. A sufficient capital was soon procured, through the confidence which many of their friends reposed in their abilities and integrity. In fact, the establishment which they made, or rather the capital which gave it existence, was the united capital of a band of relations and friends, who trusted to Dr Roebuck and Mr Garbet the management of a great part of their fortune. When all previous matters had been concerted respecting their intended establishment, the chief exertions of chemical and mechanical skill, necessary in the execution, were expected from Dr Roebuck. It fell to his share also to fix upon the best and most favourite situation for erecting their intended works. With that view Dr Roebuck examined many different places in Scotland, particularly those on both sides of the Frith of Forth; and after a careful and minute comparison of their advantages and disadvantages, he at length made choice of a spot on the banks of the river *Carron* as the most advantageous situation for the establishment of the iron manufacture. There he found they could easily command abundance of water for the necessary machinery; and in the neighbourhood of it, as well as everywhere both along the north and south-coasts of the Frith, were to be found inexhaustible quarries of ironstone, limestone, and coal. From Carron, also, they could easily transport their manufactures to different countries by sea. The communication with Glasgow at that time by land carriage, which opened up to them a ready way to the American market, was short and easy.

Many other things, that need not be here enumerated, fell to Dr Roebuck's share in preparing and providing for the introduction of this new manufacture into Scotland, particularly with respect to the planning and erection of the furnaces and machinery. To insure success in that department, nothing was omitted which ability, industry, and experience could suggest. With this view, he called to his assistance Mr Smeaton, then by far the first engineer in England. It was from him he received plans and drawings of the water-wheels and blowing apparatus, which, notwithstanding all the mechanical improvements which have been made since, remain unrivalled in any of the other iron-works erected in Britain. This was the first introduction of Mr Smeaton into Scotland, and was the occasion of various other displays of the skill and experience of that celebrated engineer in that part of the island. With the same view, and to the same effect, in a future period of his operations, he employed Mr James Watt, then of Glasgow, and had the merit of rendering that inventive genius, in the mechanical arts, better known both in this country and in England.

The necessary preparations for the establishment of the iron-works at Carron were finished in the end of the year 1759; and on the 1st January 1760 the first furnace was blown; and in a short time afterwards a second was erected.

No period of Dr Roebuck's life required from him more vigorous and laborious exertions than that of the establishment of the Carron works, and the first trials of the furnaces and machinery. His family and friends remember well the ardour and interest which he discovered; the incessant labour and watchfulness which he exerted on that occasion. Every thing was untried, the furnaces, the machinery, the materials, the workmen; the novelty of the undertaking in that country, its extent and difficulty, and the great stake at issue, were circumstances that must have occasioned much serious thought and anxiety to the partner, upon the credit of whose knowledge and experience the work had been undertaken. But the Doctor had great powers and great resources; and the first trial gave sufficient indications of future success.

For some time after the establishment of the Carron works, Dr Roebuck continued to give his attention and assistance in the general management and superintendance of them, and with him all measures of future operations were concerted. During this period, some alterations of great importance were suggested by him, and carried into effect. By carefully observing the progress of smelting in the furnaces, at first worked by bellows, besides their being subject to various accidents, the Doctor discovered the necessity of rendering the blast both stronger and more equable; and proposing, as a problem to Mr Smeaton, the best method of effecting that end, that celebrated engineer soon gave the plan of a blast by three or four cylinders, which was afterwards tried, and succeeded even beyond expectation.

When the business at Carron sunk by degrees into a matter of ordinary detail, and afforded less scope for the Doctor's peculiar talents, he was unfortunately tempted to engage in a new and different undertaking, from the failure of which he suffered a reverse of fortune, was deprived of the advantages resulting from his other works, and during the remainder of his life became subjected to much anxiety and disappointment.

The establishment of the Carron works, and the interest Dr Roebuck had in their success, had naturally turned his attention to the state of coal in the neighbourhood of that place, and to the means of procuring the extraordinary supplies of it which the iron works might in future require. With the view therefore of increasing the quantity of coal wrought in that neighbourhood, by an adventure which he thought would also turn out to his own emolument, he was induced to become lessee of the Duke of Hamilton's extensive coal and salt works at Borrowstounness. The coal there was represented to exist in great abundance, and understood to be of superior quality; and as Dr Roebuck had made himself acquainted with the most improved methods of working coal in England, and then not practised in Scotland, he had little doubt of this adventure turning out beneficial and highly lucrative. In this, however, he was cruelly disappointed. The opening of the principal stratum of coal required much longer time, and much greater expence, than had been calculated; and, after it was opened, the perpetual succession of difficulties and obstacles which occurred in the working and raising of the coal, was such as has been seldom experienced in any work of that kind. The result was, that after many years of labour and industry, there were sunk in the coal and salt works at Borrowstounness, not only his own, and the considerable fortune brought him by his wife, but the regular profits of his more successful works; and along therewith, what distressed him above every thing, great sums of money borrowed from his relations and friends, which he was never able to repay; not to mention that, from the same cause, he was, during the last twenty years of his

Roebuck. his life, subjected to a constant succession of hopes and disappointments, to a course of labour and drudgery ill suited to his taste and turn of mind, to the irksome and teasing business of managing and studying the humours of working colliers. But all these difficulties his unconquerable and persevering spirit would have overcome, if the never-ceasing demands of his coal-works, after having exhausted the profits, had not also compelled him to withdraw his capital from all his different works in succession; from the refining work at Birmingham, the vitriol work at Prestonpans, the ironworks at Carron, as well as to part with his interest in the project of improving the steam-engine, in which he had become a partner with Mr Watt, the original inventor, and from which he had reason to hope for future emolument.

It would be painful to mention the unhappy consequences of this ruinous adventure to his family and to himself. It cut off for ever the flattering prospect which they had of an independent fortune, suited to their education and rank in life. It made many cruel encroachments upon the time and occupations of a man whose mind was equally fitted to enjoy the high attainments of science, and the elegant amusements of taste. As the price of so many sacrifices, he was only enabled to draw from his colliery, and that by the indulgence of his creditors, a moderate annual maintenance for himself and family during his life. At his death, his widow was left without any provision whatever for her immediate or future support, and without the smallest advantage from the extraordinary exertions and meritorious industry of her husband.

Dr Roebuck had, some years before his death, been attacked by a complaint that required a dangerous chirurgical operation. That operation he supported with his usual spirit and resolution. In a short time he was restored to a considerable share of his former health and activity; but the effects of it never entirely left him, and [illegible] gradually impaired his constitution. [illegible] continued, till within a few [illegible] of his death, to visit his works, and to give directions to his clerks and overseers. He was confined to his bed only a few days, and died on the 17th July 1794, retaining to the last all his faculties, his spirit and good humour, as well as the great interest which he took, as a man of science and reflection, in the uncommon events which the present age has exhibited.

From a man so deeply and so constantly engaged in the detail of active business, many literary compositions were not to be expected. Dr Roebuck left behind him many *works*, but few *writings*. The great object which he kept invariably in view was to promote arts and manufactures, rather than to establish theories or hypotheses. The few essays which he left, enable us to judge of what might have been expected from his talents, knowledge, and boldness of invention, had not the active undertakings in which, from an early period of life, he was engaged, and the fatiguing details of business, occupied the time for study and investigation. A comparison of the heat of London and Edinburgh, read in the Royal Society of London June 29. 1775; experiments on ignited bodies, read there 16th Feb. 1776; observations on the ripening and filling of corn, read in the Royal Society of Edinburgh 5th June 1784—are all the writings of his, two political pamphlets excepted, which have been published. The publication of the essay on ignited bodies was occasioned by a report of some experiments made by the Comte de Buffon, from which the Comte had inferred, that *matter* is heavier when hot than when cold. Dr Roebuck's experiments, made with great accuracy before a committee of the Royal Society at London, seem to refute that notion.

It is the works and establishments projected and executed by Dr Roebuck, with the immediate and more remote effects of them upon the industry, arts, and manufactures of Scotland, which urge a just claim to the respect and gratitude of his country. This tribute is more due from the discerning part of mankind, as this species of merit is apt to be overlooked by the busy or the superficial, and to fail in obtaining its due reward. The circumstances of Dr Roebuck were, in this respect, peculiarly hard: for though, most certainly, the projector and author of new establishments highly useful to his country, and every day becoming more so, he was, by a train of unfortunate events, obliged to break off his connection with them, at an unseasonable time, when much was yet wanting to their complete success; and thus he left others in the possession, not only of the lucrative advantages now derived from them, but even in some measure of the general merit of the undertaking, to a considerable part of which he had the most undoubted claim.

The establishment of the laboratory at Birmingham in the year 1747, the first public exhibition of Dr Roebuck's chemical talents, was, at that particular period, and in the state of the arts and manufactures at that time, highly beneficial, and subservient to their future progress: and the continuance and success of it, in that place, is a proof of the advantages which many of the manufacturers receive from it. Much had already been done, and many improvements made in arts and manufactures, chiefly by the suggestions of that ingenuity and experience which, in the detail of business, might be expected from the practical artist. Dr Roebuck was qualified to proceed a step farther; to direct experience by principles, and to regulate the mechanical operation of the artist by the lights of science. The effects of that establishment extended, in a particular manner, to all that variety of manufactures in which gold and silver were required, to the preparing of materials, the simplifying of the first steps, to the saving of expence and labour, and to the turning to some account what had been formerly lost to the manufacturer. It is well known that, while Dr Roebuck resided at Birmingham, such was the opinion formed of his chemical knowledge and experience by the principal manufacturers, that they usually consulted him on any new trial or effort to improve their several manufactures; and when he left that place, they sincerely regretted the loss of that easy and unreserved communication they had with him on the subjects of their several departments.

On account of similar circumstances, the benefit to the public, from the establishment of the vitriol works at Prestonpans, in the extension and improvement of many of the arts, cannot now be exactly ascertained. The vitriolic acid is one of the most active agents in chemistry, and every discovery which renders it cheap and accessible to the chemist must be greatly subservient

to

to the progress of that science. By the establishment at Prestonpans, the price of that valuable acid was reduced from sixteen to four pence *per* pound. It is to Dr Roebuck, therefore, that chemists are indebted for being in possession of a cheap acid, to which they can have recourse in so many processes.

But Dr Roebuck's object in the prosecution of that scheme, was not so much to facilitate the chemist's labour, as to render that acid, in a much higher degree than it had formerly been, subservient to many of the practical arts. By rendering the vitriolic acid cheap, great use came to be made of it in preparing the muriatic acid, and Glauber's salts from common salts. Its use has been farther extended to many metallic processes; and it has lately been employed in separating silver from the clippings of plated copper, the use of which is very extensive.

The project and establishment, however, of the iron-works at Carron, the most extensive establishment of that kind hitherto in Britain, must be considered as Dr Roebuck's principal work. The great and increasing demand for iron in the progressive state of arts, manufactures, and commerce in Britain, and the great sums of money sent every year to the north of Europe for that article, turned the attention of chemists and artists to the means of promoting the manufacture of iron, with the view of reducing the importation of it. No person has a better founded claim to merit, in this particular, than Dr Roebuck. The smelting of iron by pitcoal, it is indeed believed, had been attempted in Britain in the beginning of the last century. In the reign of James I. several patents seem to have been granted for making hammered iron by pitcoal, particularly to the Hon. Dud Dudley and Simon Starlevant. It does not appear, however, that any progress had been made in the manufacture in consequence of these patents. In later times trials have been made by so many different persons, and in so many different places in England, nearly about the same time, that it may be difficult to say where and by whom the first attempt was made, particularly as the discoverers of such processes wished to conceal the knowledge they had gained as long as they could. But Dr Roebuck was certainly among the first who, by means of pitcoal, attempted to refine crude or pig iron, and to make bar iron of it, instead of doing it by charcoal, according to the former practice: And he was, without all question, the person who introduced that method into Scotland, and first established an extensive manufacture of it. It is not meant to ascribe to him the sole merit of the establishment at Carron. No man was ever more ready than he was to do justice to the abilities and spirit of his friends and partners Messrs Garbet, Caddell, &c. who first embarked with him in that great undertaking. But still it may be said with truth, that the original project of the iron-works at Carron, the chemical knowledge and experience on which they were founded, the complicated calculations which were previously required, the choice of the situation, the general conduct and direction of the buildings and machinery, the suggestion of many occasional improvements, together with the removal of many unforeseen obstacles and difficulties, which occurred in the infant state of that establishment, were, in a great measure, the work and labour of Dr Roebuck. Nor can it, with the least shadow of justice, detract from his merit, that a larger capital, and greater expence than was at first calculated, have been found necessary to bring the works at Carron to their present state of perfection; or, that great alterations and improvements have taken place, during the course of forty years, in a great and progressive establishment. In all works of that kind, the expence exceeds the calculation. The undertakers, even of the latest iron works which have been erected, notwithstanding all the advantages obtained from recent experience, will be ready to acknowledge, that, in these respects, there is little room to blame the original projector of the first establishment of that kind in Scotland. But the best, and most infallible proof of Dr Roebuck's merit, and of the sound principles on which these works were established, is the present prosperous state of that establishment, the great perfection of many branches of their manufactures, and particularly the many extensive and flourishing iron-works which have since been erected upon the model of Carron in different parts of Scotland, at Cleugh, Clyde, Muirkirk, and Devon. It cannot be denied that all these works have sprung from the establishment at Carron, and are ultimately founded upon the knowledge and experience which have been obtained from them; for some of the partners, or overseers of these new works, and many of the workmen, have been, at one time or another, connected with that of Carron. Hence, then, it is owing to the projector and promoter of the establishment at Carron, that Scotland is, at this moment, benefited to the amount of many hundred thousand pounds, in working up the raw materials of that manufacture found in the country itself, and which, previous to that establishment, was of no value whatever. Such are the *present*, but scarcely any idea can be formed of the *future*, advantages to this country, which may be derived from the extension of the iron manufacture. About 60,000 tons of iron have been annually imported into Great Britain for more than twenty years past; and though there has been for some time about 20,000 tons of bar iron made in Britain by pitcoal, yet the foreign imported iron has suffered little or no diminution in quantity. The great consumption of iron, no doubt, is owing to the various improvements of late years, and the general extension throughout all Europe of commerce and the arts. The manufacture of iron must therefore continue to increase; and Scotland, abounding everywhere in ironstone, pitcoal, and in command of water for machinery, has the prospect of obtaining the largest share of it.

To the establishment of the Carron works, and to the consequences of that establishment, may be ascribed also the existence of other public works in Scotland of great importance and utility. The opening of a communication by water betwixt the Forth and the Clyde had long been projected, and frequently the subject of conversation in Scotland, but nothing in fact had been attempted. The establishment of the iron-works at Carron soon called forth sufficient interest and enterprise to bring about the execution of this grand design. Some of the partners of the Carron company, foreseeing the advantages they would derive from such a communication, proposed, at their own expence, to execute a small canal; and, after taking the preparatory steps, actually applied to Parliament to obtain authority for that purpose. But the project of the small canal not meeting

Roebuck.

meeting with the approbation of some noblemen and gentlemen in that part of Scotland, they opposed the bill, and obliged themselves to execute a greater canal, which has now been many years finished, and is found to be of the greatest advantage to the trade and commerce of Scotland. The merit of this undertaking is not meant to be ascribed to Dr Roebuck, excepting in so far as it necessarily arose from the establishment of the Carron company, of which he was the original projector; and it may reasonably be doubted whether, without that establishment, it would have yet taken place. Several other canals have, since that time, been executed in different parts of Scotland, and other very important ones are at present projected.

The different establishments which Dr Roebuck made at Borrowstounness in carrying on the coal and salt works there, though ultimately of no advantage to himself, were attended, during the course of thirty years, with the most beneficial effects upon the trade, population, and industry of that part of Scotland. They were the means also of adding very considerably to the public revenue. Previous to the time these works fell under Dr Roebuck's management, they produced no advantage either to the proprietor, to the adventurers, or to the public. But by his mode of conducting them upon a more extensive plan, by opening up new seams of coal, and of better quality, he was enabled to export a very considerable quantity, to increase the quantity of salt, and of course the revenue arising from these articles. In these works, and in the management of a large farm, Dr Roebuck gave employment to near a thousand persons at Borrowstounness and in the neighbourhood.

[illegible] by the different establishments which he projected and executed, but by many other things [illegible] connected with them, that Dr Roebuck's labours were beneficial to Scotland. Along with them he [illegible] a [illegible] enterprise and industry, [illegible] in Scotland, [illegible] labour, and gave birth to many other useful projects. He brought from England, then much farther advanced in arts and industry, many ingenious and industrious workmen, at great expence, who, by their instructions and example, communicated and diffused skill and knowledge to others. At all times Dr Roebuck held out liberal encouragement to rising genius and industrious merit; and spared no expence in making trials of improvements and discoveries which were connected with the different projects and works which he was carrying on.

Such was the active and useful life of Dr Roebuck; a man of no common cast, who united, in a very high degree, a great number of solid and brilliant talents, which, even separately, fall to the lot of but few individuals. Distinguished by an ardent and inventive mind, delighting in pursuit and investigation, always aspiring at something beyond the present state of science and art, and eagerly pressing forward to something better or more perfect, he thus united energies the most powerful with the most unwearied and persevering industry. To that peculiarity of imagination, so fitted for scientific pursuit, which readily combines and unites, which steadily preserves its combinations before the eye of the mind, and quickly discovers relations, results, and consequences, was added in his character, great promptitude and firmness in decision. Strongly and early impressed with the great importance of applying chemical and physical knowledge to the useful arts, to the melioration of civil life, he never lost sight of that favourite view; and discovered great boldness and resource in the means and expedients which he adopted to promote it. He was certainly master of the best philosophy of chemistry known in the earlier parts of his life; and though in every stage of that science he marked and understood the progress of the discoveries, yet his numerous avocations did not permit him to follow them out by experimental processes of his own. Upon that, and indeed almost upon every subject, his mind readily grasped the most useful and substantial points, and enabled him to throw out such hints and hypotheses as marked him the man of genius.

During the course of a regular education, both at Edinburgh and at Leyden, Dr Roebuck studied the classic authors with great attention, particularly the historical and political parts of their works. Upon these subjects he had read much, selected with judgment, and was well acquainted with the facts and philosophy of ancient governments. This taste he carried with him, and improved in every period of his life, and in every situation. It abundantly rewarded him for the earnestness and diligence with which it had been acquired. It became his favourite resource, and indeed one of the chief enjoyments of his life. Possessing the happy talent of turning his mind from serious and fatiguing, to elegant and recreating pursuits, it was no uncommon thing with him to return from the laboratory or the coalpit, and draw relaxation or relief from some one or other of the various stores of classical learning.

No man was better acquainted with the history of his country than Dr Roebuck, or more admired and revered the constitution of its government. By temper and education he was a Whig, and at all times entered with great warmth into the political disputes and controversies which agitated parties in the different periods of his life. If the natural warmth of his temper, and his enthusiasm on these subjects, led him, on some occasions, beyond the bounds of candid argumentation, his quick sense of decorum, and his perfect habits of good manners, produced an immediate atonement, and restored the rights of elegant and polished conversation.

The general acquaintance which Dr Roebuck had acquired with natural and experimental philosophy, together with his classical and political knowledge, rendered him an agreeable companion to the learned almost of every department, and procured him the attachment and friendship of many of the first literary characters in Britain. With his friend Dr Black he lived till his death in close habits of intimacy; and he often acknowledged, with much frankness, the advantages which he derived, in his various pursuits, from a free and unreserved communication with that eminent chemist.

The amiable dispositions of sensibility, humanity, and generosity, which strongly marked his character, in the general intercourse of society, were peculiarly preserved and exercised in the bosom of his family, and in the circle of his friends. In the various relations of husband, father, friend, or master, and in the discharge of the respective duties arising from them, it would not be easy to do justice to his character, or to determine in which

Roemer. of them he moſt excelled; nor muſt it be forgot, for it reflected much honour on his benevolent heart, that his workmen not only found him at all times a kind and indulgent maſter, but many of them, when their circumſtances required it, a ſkilful and compaſſionate phyſician, who cheerfully viſited the humbleſt receſſes of poverty, and who attached them to his ſervice by multiplied acts of generoſity and kindneſs.

ROEMER (Olaus), a noted Daniſh aſtronomer and mathematician, was born at Arhuſen in Jutland, 1644; and at 18 years of age was ſent to the univerſity of Copenhagen. He applied aſſiduouſly to the ſtudy of the mathematics and aſtronomy, and became ſo expert in thoſe ſciences, that when Picard was ſent by Louis the XIV. in 1671, to make obſervations in the north, he was greatly ſurpriſed and pleaſed with him. He engaged him to return with him to France, and had him preſented to the king, who honoured him with the dauphin as a pupil in mathematics, and ſettled a penſion upon him. He was joined with Picard and Caſſini, in making aſtronomical obſervations; and in 1672 he was admitted a member of the Academy of Sciences.

During the ten years he reſided at Paris, he gained great reputation by his diſcoveries; yet it is ſaid he complained afterwards, that his coadjutors ran away with the honour of many things which belonged to him. Here it was that Roemer, firſt of any one, found out the velocity with which light moves, by means of the eclipſes of Jupiter's ſatellites. He had obſerved for many years, that when Jupiter was at his greateſt diſtance from the earth where he could be obſerved, the emerſions of his firſt ſatellite happened conſtantly 15 or 16 minutes later than the calculation gave them. Hence he concluded, that the light reflected by Jupiter took up this time in running over the exceſs of diſtance; and conſequently that it took up 16 or 18 minutes in running over the diameter of the earth's orbit, and 8 or 9 in coming from the ſun to us, provided its velocity was nearly uniform. This diſcovery had at firſt many oppoſers; but it was afterwards confirmed by Dr Bradley in the moſt ingenious and beautiful manner.

In 1681 Roemer was recalled to his native country by Chriſtian the Vth King of Denmark, who made him profeſſor of aſtronomy at Copenhagen. The king employed him alſo in reforming the coin and the architecture, in regulating the weights and meaſures, and in meaſuring and laying out the high roads throughout the kingdom; offices which he diſcharged with the greateſt credit and ſatisfaction. In conſequence he was honoured by the king with the appointment of chancellor of the exchequer and other dignities. Finally, he became counſellor of ſtate, and burgomaſter of Copenhagen, under Frederic the IV. the ſucceſſor of Chriſtian. Roemer was preparing to publiſh the reſult of his obſervations, when he died the 19th of September 1710, at 66 years of age: but this loſs was ſupplied by Horrebow, his diſciple, then profeſſor of aſtronomy at Copenhagen, who publiſhed, in 4to, 1753, various obſervations of Roemer, with his method of obſerving, under the title of *Baſis Aſtronomiæ*.—He had alſo printed various aſtronomical obſervations and pieces, in ſeveral volumes of the Memoirs of the Royal Academy of Sciences at Paris, of the inſtitution of 1666, particularly vol. 1. and 10. of that collection.

ROLLOCK (Robert), the firſt principal of the college of Edinburgh, was the ſon of David Rollock of *Poo houſe*, or, as it is now written, *Powis*, in the neighbourhood of Stirling. He was born in 1555; and learned the rudiments of the Latin tongue under one Mr Thomas Buchanan, who kept, ſays Archbiſhop Spottiſwood, a famous ſchool at that time, and was, according to Dr Mackenzie, one of the moſt eminent grammarians in Scotland. Where Mr Buchanan kept his ſchool, neither of theſe authors has informed us.

From ſchool Mr Rollock was ſent, we know not in what year, to the univerſity of St Andrews, and admitted a ſtudent in St Salvator's college. His progreſs in the ſciences, which were then taught, was ſo great and ſo rapid, that he had no ſooner taken his degree of M. A. than he was choſen a profeſſor of philoſophy, and immediately began to read lectures in St Salvator's college. This muſt have been at a very early period of life; for he quitted St Andrews in the year 1583, when, according to Mackenzie, he had taught philoſophy for ſome time in that univerſity.

Not long before this period, the magiſtrates of Edinburgh having petitioned the king to erect a univerſity in that city, he granted them a charter under the great ſeal, allowing them all the privileges of a univerſity; and the college being built in 1582, they made choice of Mr Rollock to be their principal and profeſſor of divinity.

At what time he was admitted into holy orders, by whom he was ordained, or indeed whether he ever was ordained, has been the ſubject of ſome acrimonious controverſy; but it is a controverſy which we ſhall not revive; for, conſidering the manner in which orders were then conferred in Scotland, the queſtion is ſurely of very little importance. It is certain that he became famous in the univerſity, and among his countrymen in general, for his lectures in theology, and for the perſuaſive power of his preaching; for Calderwood affirms, that, in 1589, he and Mr Robert Bruce, another popular orator, made the Earl of Bothwel ſo ſenſible of his ſinful and vicious courſes, that, upon the 9th of November his lordſhip humbled himſelf upon his knees in the eaſt church in the forenoon, and in the high church in the afternoon, confeſſing before the people, with tears in his eyes, his diſſolute and licentious life, and promiſing to prove, for the future, another man.

In the year 1593, Principal Rollock and others were appointed by the ſtates of parliament to confer with the popiſh lords; and in the next year he was one of thoſe who, by the appointment of the general aſſembly of the church, met at Edinburgh in the month of May, and preſented to his majeſty a paper, entitled, *The dangers which, through the impunity of* EXCOMMUNICATED PAPISTS, TRAFFICKERS WITH THE SPANIARDS, *and other enemies of the religion and eſtate, are imminent to the true religion profeſſed within this realm, his Majeſty's perſon, crown, and liberty of this our native country.* His zeal againſt Papiſts was indeed ardent; and he ſeems to have adopted that judaical doctrine, which was embraced in ſome degree by all the reformers, that it is the duty of the civil magiſtrate to puniſh idolatry with death.

In the year 1595 he was nominated one of the commiſſioners for the viſitation of colleges. Theſe commiſſioners

Rollock.

missioners were empowered to visit all the colleges in the kingdom, to inquire into the doctrine and life of the several masters, the discipline used by them, the state of their rents and living, and to make their report to the next assembly.

In 1596, the factious behaviour of some of the ministers having drawn upon them the just resentment of the king, our principal was employed, on account of his moderation, to soften that resentment, and to turn his majesty's wrath against the *Papists!* In the year 1597, he was chosen moderator of the General Assembly—the highest dignity in the Scottish church; and he had the influence to get some great abuses redressed. Being one of fourteen ministers appointed by this assembly to take care of the affairs of the church, the first thing which he did was to procure an act of the legislature, restoring to the prelates their seats in parliament. He had here occasion for all his address; for he had to reconcile to this measure, not only such of the ministers as abhorred all kinds of subordination in the church, but likewise many of the lay lords, who were not delighted with the prospect of such associates in parliament as the Scotch prelates were at that period (A).

Though he spent the greater part of his life in conducting the affairs of the church, we have the authority of Spottiswood for saying, that he would have preferred retirement and study to the bustle of public life, especially at that period of faction and fanaticism, his feeble [illegible] was not [illegible] and his inclination [illegible] him to the college; and his [illegible] with the stone; [illegible] long bore with the fortitude [illegible] a Christian. He died at Edinburgh [illegible] 1598, in the [illegible] year of his [illegible] brethren, with [illegible] more [illegible] [illegible] A Commentary [illegible] Book of [illegible] on St Paul's Epistle to the [illegible] Edinburgh, 1590. 3. A Commentary on the [illegible], 4to, Edinburgh, 1591. 4. A Logical Analysis of St Paul's Epistle to the Romans, 8vo, Edinburgh, 1594. 5. Some Questions and Answers concerning the Covenant of Grace and the Sacraments, 8vo, Edinburgh, 1596. 6. A Treatise of Effectual Calling, 8vo, Edinburgh, 1597. 7. A Commentary on the Epistles of St Paul to the Thessalonians and Philemon, 8vo, Geneva, 1597. 8. A Commentary upon Fifteen Select Psalms, 8vo, Geneva, 1598. 9. A Commentary on the Gospel of St John, with a harmony of the Four Evangelists upon the Death, Resurrection, and Ascension of Jesus Christ, 8vo, Geneva, 1599. 10 Certain Sermons on Several Places of St Paul's Epistles, 8vo, Edinburgh, 1598. 11. A Commentary upon the Epistle to the Colossians, 8vo, published at Geneva, 16[illegible]. 12. A Logical Analysis of the Epistle to the Hebrews, 8vo, Edinburgh, 1605. 13. A Logical Analysis of the Epistle to the Galatians, 8vo, London, 1602. 14. A Commentary upon the Two First Chapters of the First Epistle of St Peter, 8vo, London, 1603. 15 and 16. A Treatise of Justification, and another of Excommunication, both in 8vo, London, 1604. All these works, except the sermons, are in Latin. That Principal Rollock was held in high estimation in the college over which he presided, is made at least probable by the following [illegible]taph:

Te Rollore, extincto, Urbs mæsta, Academia mæst[illegible];
Et tota exequiis Scotia mæsta tuis.
Uno in te nobis dederat Deus omnia, in uno
Te Deus eripuit omnia quæ dederat.

Roses.
Rota.

ROSES OTTER (or essential oil) OF. In the *Encyclopædia*, under the word ROSES, we have given one receipt for making this very high-priced perfume; and we shall here give another; which, whether it be as effectual or not, is at least simpler and less expensive. It is by an officer who was in the country where the Otter is prepared, and who assisted in making it himself; and is as follows:

"Take a very large glazed earthen or stone jar, or a large clean wooden cask; fill it with the leaves of the flowers of roses, very well picked, and freed from all seeds and stalks; pour on them as much pure spring water as will cover them, and set the vessel in the sun, in the morning at sun-rise, and let it stand till the evening, then take it into the house for the night; expose it, in this manner, for six or seven successive days, and, at the end of the third or fourth day, a number of particles, of a fine yellow oily matter, will float on the surface, which, in two or three days more, will gather into a scum, which is the otter of roses. This is taken up by some cotton, tied to the end of a piece of stick, and squeezed with the finger and thumb into a small phial, which is immediately well stopped; and this is repeated for some successive evenings, or while any of this fine essential oil rises to the surface of the water."

Dr Donald Monro, who communicated this receipt to the Royal Society of Edinburgh, says, that he has been informed, that some few drops of this essential oil have more than once been collected by distillation in London, in the same manner as the essential oils of other plants.

ROTA ARISTOTELICA, or *Aristotle's Wheel*, denotes a celebrated problem in mechanics, concerning the motion

(A) The constitution of the Scotch church was, at this period, a strange system of inconsistency and contradiction. It was, in fact, presbyterian; for ecclesiastical discipline was administered then, as at present, by kirk-sessions, presbyteries, and general assemblies; and there was not a reformed bishop in the kingdom. Whether provincial synods were then in use, the writer of this note does not at present recollect. The king, however, who was meditating the restoration of episcopacy, conferred the estates, or part of the estates, belonging to the different sees, upon the most eminent parochial ministers, and dignified them with the title of bishops; though it does not appear that they had any jurisdiction over their brethren; and though they were certainly not *ex officio* so much as moderators of the presbyteries within the bounds of which their churches were situated. These were the men for whom Mr Rollock exerted himself to obtain seats in the parliament.

Rota, Rowning.

tion or rotation of a wheel about its axis; so called because first noticed by Aristotle.

The difficulty is this. While a circle makes a revolution on its centre, advancing at the same time in a right line along a plane, it describes, on that plane, a right line which is equal to its circumference. Now if this circle, which may be called the deferent, carry with it another smaller circle, concentric with it, like the nave of a coach wheel; then this little circle, or nave, will describe a line in the time of the revolution, which shall be equal to that of the large wheel or circumference itself; because its centre advances in a right line as fast as that of the wheel does, being in reality the same with it.

The solution given by Aristotle, is no more than a good explication of the difficulty.

Galileo, who next attempted it, has recourse to an infinite number of infinitely little vacuities in the right line described by the two circles; and imagines that the little circle never applies its circumference to those vacuities; but in reality only applies it to a line equal to its own circumference; though it appears to have applied it to a much larger. But all this is nothing to the purpose.

Tacquet will have it, that the little circle, making its rotation more slowly than the great one, does on that account describe a line longer than its own circumference; yet without applying any point of its circumference to more than one point of its base. But this is no more satisfactory than the former.

After the fruitless attempts of so many great men, M. Dortous de Meyran, a French gentleman, had the good fortune to hit upon a solution, which he sent to the Academy of sciences; where being examined by Mess. de Louville and Soulmon, appointed for that purpose, they made their report that it was satisfactory. The solution is to this effect:

The wheel of a coach is only acted on, or drawn in a right line; its rotation or circular motion arises purely from the resistance of the ground upon which it is applied. Now this resistance is equal to the force which draws the wheel in the right line, inasmuch as it defeats that direction; of consequence the causes of the two motions, the one right and the other circular, are equal. And hence the wheel describes a right line on the ground equal to its circumference.

As for the nave of the wheel, the case is otherwise. It is drawn in a right line by the same force as the wheel; but it only turns round because the wheel does so, and can only turn in the same time with it. Hence it follows, that its circular velocity is less than that of the wheel, in the ratio of the two circumferences; and therefore its circular motion is less than the rectilinear one. Since then it necessarily describes a right line equal to that of the wheel, it can only do it partly by sliding, and partly by revolving, the sliding part being more or less as the nave itself is smaller or larger.—*Hutton's Dictionary.*

ROWNING (John), an ingenious English mathematician and philosopher, was fellow of Magdalen College, Cambridge, and afterwards Rector of Anderby in Lincolnshire, in the gift of that Society. He was a constant attendant at the meetings of the Spalding Society, and was a man of a great philosophical habit and turn of mind, though of a cheerful and companionable disposition. He had a good genius for mechanical contrivances in particular. In 1738 he printed at Cambridge, A Compendious System of Natural Philosophy, in 2 vols 8vo; a very ingenious work, which has gone through several editions. He had also two pieces inserted in the Philosophical Transactions, viz. 1. A Description of a Barometer, wherein the Scale of Variation may be increased at pleasure; vol. 38. p. 39. And, 2. Directions for making a Machine for finding the Roots of Equations universally, with the Manner of using it; vol. 60. p. 240.—Mr Rowning died at his lodgings in Carey-street, near Lincoln's-Inn Fields, the latter end of November 1771, at 72 years of age.

Though a very ingenious and pleasant man, he had but an unpromising and forbidding appearance: he was tall, stooping in the shoulders, and of a sallow down-looking countenance.

ROY-ROYAN, in Bengal, the chief officer in the revenue department, next to the Dewan under the native government.

RUTHERFORD (John, M. D.), one of the illustrious founders of the medical school in the university of Edinburgh, was the son of the Rev. Mr Rutherford minister of Yarrow, in the county of Selkirk, North Britain. He was born on the 1st August 1695, and received the rudiments of his education at the parish school of Selkirk; where, from his future proficiency, there is every reason to believe that he made a rapid progress in the knowledge of the Latin and Greek languages.

After the death of his father, he went to Edinburgh in 1708 or 1710, where, in the university, he applied himself to the study of classical literature, mathematics, and natural philosophy. The celebrated Dr was then so highly respected for his medical skill, that it is not improbable but that a laudable desire of obtaining a portion of similar fame may have turned the attention of young Rutherford to the study of medicine. Be that as it may, he engaged himself apprentice to Mr Alexander Nesbit, at that time an eminent surgeon in Edinburgh, with whom he remained till 1716, when he went to London. There he attended some hospitals, and the lectures read on anatomy by Dr Douglas, on surgery by André, and on materia medica by Strother.

After a year's residence in London, he returned to Edinburgh; and having settled his affairs in that city, he went to Leyden, which, from the lectures of Boerhaave, was then the most celebrated medical school in Europe. In 1719 he went into France, and was at the end of July in that year admitted to the degree of M.D. in the university of Rheims. He passed the following winter in Paris, chiefly for the sake of Winslow's private demonstrations in anatomy; and in 1720 he returned to Britain.

In 1721 he settled as a physician in Edinburgh; and soon afterwards Drs Rutherford, Sinclair, Plummer, and Innes, purchased a laboratory, where they prepared compound medicines. This was an art then but little known in Scotland; and as a commercial speculation, the laboratory must therefore have proved very advantageous to the partners. But they had higher objects in view than commerce. They demonstrated, as far as they were then known, the operations of chemistry

mistry to a [illegible]rous audience; [illegible] soon afterwards, by the ad[vi]ce of their old master Boerhaave, they extended their lectures to the other branches of physic. In 1725 they were appointed joint professors in the university; where, we believe, each, for some time, read lectures in every department of medical science, anatomy excepted, and carried forward their classes in rotation. The anatomical lectures were read by the elder Monro, who had been settled a year or two before them in Edinburgh, and whose eminence in that department is known to all Europe.

On the death of Dr Innes, a particular branch of medical science was allotted to each of the other three professors. Dr Plummer was appointed professor of chemistry and materia medica, Dr Sinclair of the institutes of physic, and Dr Rutherford of the practice; and thus was a regular medical school established in Edinburgh by Monro, Plummer, Sinclair, and Rutherford. The lectures on the institutes and practice of physic were then, and for many years afterwards, delivered in Latin; and such was Dr Rutherford's command of that language, that on every thing connected with medicine, he talked in it more fluently than in the language of his country.

Whether it was any improvement in the mode of medical education in Edinburgh to change the language of the lectures from Latin to English, is perhaps more than questionable. We have now dispersed over the country a number of illiterate men, practising as surgeons, and even as physicians, who never could have boasted of having gone through a regular course of medical instruction, had the lectures continued to be deli- [illegible] language in which they were begun. Foreigners too, would not have been under the necessity [illegible]ng a new language, before they could enter on [illegible] the cultivation of which they came to [illegible] though the medical classes might not have been so crowded perhaps as at present, the individuals composing them would have been at least as respectable. Whether Dr Rutherford reasoned in this way we know not; but he continued to lecture in Latin as long as he filled the practical chair.

Rutherford.

About the year 1748 he introduced a very great improvement in the course of medical education. Sensible that abstract lectures on the symptoms and the mode of treating various diseases, of which the students know little but the names, could scarcely be of any benefit, he had for some time encouraged his pupils to bring patients to him on Saturday, when he inquired into the nature of their diseases, and prescribed for them in the presence of the class. This gave rise to the course of *clinical* lectures; the utility of which was so obvious, that it was enacted, by a decree of the senate of the university, that no man should be admitted to an examination for his doctor's degree, who had not attended those lectures; to which an excellent hospital, then lately erected (see EDINBURGH, in the *Encyclopædia*), gave the professors every opportunity of doing ample justice. To men who mean to live by the practice of physic, and have no inordinate ambition to raise their fame by fanciful theories, this is perhaps the most valuable course of lectures that is given in Edinburgh; and if so, Dr Rutherford must be considered as one of the greatest benefactors of the medical school.

To untried theories in physic he was indeed no friend; and we have heard a favourite and very able pupil of his, who knew him well, and respected him highly, affirm that, to his knowledge, Dr Rutherford retained his professorship longer than he otherwise would have chosen to do; merely that he might keep out a speculatist, whom he knew to be aspiring to the practical chair. Finding at last in the late Dr John Gregory (see GREGORY, *Encycl.*) a successor entirely to his mind, he resigned to him in 1765, after having taught medicine in its different departments for upwards of forty years. He lived, after this period, loved by his friends, and revered by many eminent physicians, who had been his pupils, till 1779, when he died in Edinburgh, where he had spent the greater part of his life, in the 84th year of his age.

S.

SACCHAROMETER, the name given, by Mr Richardson of Hull, to an instrument invented by him for ascertaining the value of worts, and the strength of different kinds of malt liquors. In plain English, the name signifies a *measurer of sweetness*; and therefore, if etymology were to be attended to, the instrument should be employed merely as a measurer of the sweetness of worts. It is in fact best adapted for this purpose, being merely an hydrometer contrived to ascertain the specific gravity of worts, or rather to compare the weight of worts with that of equal quantities of the water employed in the brewery where the instrument is used.

Saccharometer.

The principle which suggested the invention of the instrument to Mr Richardson is as follows: The menstruum or water, employed by the brewer, becomes heavier or more dense by the addition of such parts of the materials as have been dissolved or extracted by, and thence incorporated with it: the operation of boiling, and its subsequent cooling, still adds to the density of it by evaporation; so that when it is submitted to the action of fermentation, it is more dense than at any other period.

In passing through this operation of nature, a remarkable alteration takes place. The fluid no sooner begins to ferment than its density begins to diminish; and as the fermentation is more or less perfect, the fermentable matter, whose accession has been traced by the increase of density, becomes more or less attenuated, and in lieu of every particle thus attenuated, a spirituous particle, of less density than water, is produced: so that when the liquor is again in a state of quietude, it is so much specifically lighter than it was before, as the action of fermentation has been capable of attenuating the component parts of its acquired density; and, indeed, were it practicable to attenuate the whole, the

liquor would become lighter or less dense than water; because the quantity of spirit produced from, and occupying the place of the fermentable matter, would diminish the density of the water in a degree bearing some proportion to that in which the latter had increased it.

From these facts, the reader, who is acquainted with hydrostatical principles, will be able to construct a saccharometer for himself. Brewers, who are strangers to these principles, we must refer to Mr Richardson's book for details, which our limits permit us not to give.

SAGITTA, in astronomy, the *Arrow* or *Dart*, a constellation of the northern hemisphere near the eagle, and one of the 48 old asterisms.

SAHARA, or, as it is sometimes written, ZAARA, the Great Desert, is a vast ocean of sand in the interior parts of Africa, which, with the lesser deserts of Bornou, Bilma, Barca, Sort, &c. is equal in extent to about one half of Europe. If the sand be considered as the ocean, the Sahara has its gulphs and bays, as also its islands, or OASES, fertile in groves and pastures, and in many instances containing a great population, subject to order and regular government.

The great body, or western division of this ocean, comprised between Fezzan and the Atlantic, is no less than 50 caravan journeys across, from north to south; or from 750 to 800 G. miles; and double that extent in length: without doubt the largest desert in the world. This division contains but a scanty portion of islands (or oases), and those also of small extent: but the eastern division has many, and some of them very large. Fezzan, Gadamis, Taboo, Ghanat, Agadez, Augela, Berdoa, are amongst the principal ones: besides which, there are a vast number of small ones. In effect, this is the part of Africa alluded to by Strabo, when he says from *Cneius Piso*, that Africa may be compared to a leopard's skin.

From the best inquiries that Mr Park could make when a kind of captive among the Moors at Ludamar, the Western Desert, he says, may be pronounced almost destitute of inhabitants; except where the scanty vegetation, which appears in certain spots, affords pasturage for the flocks of a few miserable Arabs, who wander from one well to another. In other places, where the supply of water and pasturage is more abundant, small parties of the Moors have taken up their residence. Here they live, in independent poverty, secure from the tyrannical government of Barbary. But the greater part of the desert, being totally destitute of water, is seldom visited by any human being; unless where the trading caravans trace out their toilsome and dangerous route across it. In some parts of this extensive waste, the ground is covered with low stunted shrubs, which serve as land marks for the caravans, and furnish the camels with a scanty forage. In other parts, the disconsolate wanderer, wherever he turns, sees nothing around him but a vast interminable expanse of sand and sky; a gloomy and barren void, where the eye finds no particular object to rest upon, and the mind is filled with painful apprehensions of perishing with thirst. Surrounded by this dreary solitude, the traveller sees the dead bodies of birds, that the violence of the wind has brought from happier regions; and, as he ruminates on the fearful length of his remaining passage, listens with horror to the voice of the driving blast; the only sound that interrupts the awful repose of the desert.

The few wild animals which inhabit these melancholy regions, are the antelope and the ostrich; their swiftness of foot enabling them to reach the distant watering-places. On the skirts of the desert, where the water is more plentiful, are found lions, panthers, elephants, and wild boars.

Of domestic animals, the only one that can endure the fatigue of crossing the desert is the camel. It is therefore the only beast of burden employed by the trading caravans which traverse, in different directions, from Barbary to Nigritia. The flesh of this useful and docile creature, though to our author's taste it was dry and unsavory, is preferred by the Moors to all others. The milk of the female, he says, is in universal esteem, and is indeed pleasant and nutritive.

That the desert has a dip towards the east, as well as the south, seems to be proved by the course of the Niger. Moreover, the highest points of North Africa, that is to say, the mountains of Mandinga and Atlas, are situated very far to the west. The desert, for the most part, abounds with salt. But we hear of salt mines only in the part contiguous to Nigritia, from whence salt is drawn for the use of those countries, as well as of the Moorish states adjoining; there being no salt in the Negro countries south of the Niger. There [illegible] the eastern part of the desert.

SAI, a large town on the banks of the Niger, or at least very near to that river, which Mr Park says strongly excited his curiosity. It is completely surrounded by two very deep trenches, at about two hundred yards distant from the walls. On the top of the trenches are a number of square towers; and the whole has the appearance of a regular fortification. Inquiring into the origin of this extraordinary entrenchment, our author learned from two of the town's people the following particulars; which, if true, furnish a mournful picture of the enormities of African wars.

About fifteen years before our traveller visited Sai, when the King of Bambarra desolated Maniana, the Dooty of Sai had two sons slain in battle, fighting in the king's cause. He had a third son living; and when the king demanded a further reinforcement of men, and this youth among the rest, the Dooty refused to send him. This conduct so enraged the king, that when he returned from Maniana, about the beginning of the rainy season, and found the Dooty protected by the inhabitants, he sat down before Sai with his army, and surrounded the town with the trenches which had attracted our author's notice. After a siege of two months, the towns-people became involved in all the horrors of famine; and whilst the king's army were feasting in their trenches, they saw with pleasure the miserable inhabitants of Sai devour the leaves and bark of the Bentang tree that stood in the middle of the town. Finding, however, that the besieged would sooner perish than surrender, the king had recourse to treachery. He promised, that if they would open the gates, no person should be put to death, nor suffer any injury, but the Dooty alone. The poor old man determined to sacrifice himself, for the sake of his fellow-citizens, and immediately walked over to the king's army, where he was put to death. His son, in attempting to escape, was caught and massacred in the trenches; and the rest of the towns-people were carried away captives, and sold as slaves to the different Negro traders.

traders. Sai is placed by Major Rennel in 14° N. Lat. and 3° 7′ West. Long.

SAINT CATHERINE, a Portuguese island in the South Sea, not far distant from the coast of Brazil. It was visited by La Perouse, who ascertained it to lie between 27° 19′ 10″, and 27° 49′ N. Lat. and its most northerly point to be in 49° 49′ longitude west from Paris. Its breadth from east to west is only two leagues; and it is separated from the main land by a channel only 200 toises broad. On the point which stretches furthest into this channel is situated the city of Nostra-Senora del Destero, the capital of the government, and the place of residence of the governor. It contains at most 3000 souls, and about 400 houses. Its appearance is exceedingly pleasant. According to Frezier's account, this island served, in 1712, as a retreat to vagabonds, who made their escape from different parts of the Brazils; who were only nominal subjects of Portugal, and who acknowledged no authority whatever. The country is so fertile, that they were able to subsist without any succour from the neighbouring colonies: and they were so destitute of money, that they could neither tempt the cupidity of the governor-general of the Brazils, nor inspire him with any desire of subduing them. The ships that touched at the island gave them in exchange for their provisions nothing but clothes and shirts, of which they were in the utmost want. It was not till about 17[illegible] that the court of Lisbon established a regular government in the island of St Catherine, and the parts of the continent adjacent. This government extends [illegible] and [illegible] from the river San Francisco [illegible] Grande; its population being about [illegible] there are so great a number of [illegible] that probably it will [illegible] considerable. The soil is ex[illegible] all sorts of fruit, vegetables, and corn, almost spontaneously. It is covered with trees of [illegible] green, but they are so interwoven with briars and creeping plants, that it is impossible to get through the forests otherwise than by opening a path with a hatchet. Danger is besides to be apprehended from snakes, whose bite is mortal. The habitations, both on the island and continent, are all close to the sea side. The woods that surround them are delightfully fragrant, owing to the great number of orange trees and other odoriferous trees and shrubs that they contain. But, notwithstanding all these advantages, the country is very poor, and totally destitute of manufactured commodities, so that the peasants are almost naked, or else covered with rags. Their soil, which is very fit for the cultivation of sugar, remains unproductive for the want of slaves, whom they are not rich enough to purchase. The whale fishery is very successful; but it is the property of the crown, and is farmed by a company at Lisbon, which has three considerable establishments upon the coast. Every year they kill about 400 whales; the produce of which, as well oil as spermaceti, is sent to Lisbon by the way of Rio-Janeiro. The inhabitants are idle spectators of this fishery, from which they derive not the smallest advantage. La Perouse gives a very amiable picture, however, of their hospitality to strangers.

SALT. See CHEMISTRY *Index*, in this *Suppl.*

SALT-Mines of *Vielicza*, near Cracow in Poland, are very extraordinary caverns; for a description of which we referred, in the article SALT (*Encycl.*) to M. Bernard in the *Journal de Physique* for the year 1786. Some of our readers have complained of this, and requested an account of them in the *Supplement*. With this request we shall comply, by giving them Mr Wraxall's description of these caverns *.

"After being let down (says he) by a rope to the depth of 230 feet, our conductors led us through galleries, which, for loftiness and breadth, seemed rather to resemble the avenues to some subterranean palace, than passages cut in a mine. They were perfectly dry in every part, and terminated in two chapels composed entirely of salt, hewn out of the solid mass. The images which adorn the altars, as well as the pillars and ornaments, were all of the same transparent materials; the points and spars of which, reflecting the rays of light from the lamps which the guides held in their hands, produced an effect equally novel and beautiful. Descending lower into the earth by means of ladders, I found myself in an immense hall or cavern of salt, many hundred feet in height, length, and dimensions, the floor and sides of which were cut with exact regularity. A thousand persons might dine in it without inconvenience, and the eye in vain attempted to trace or define its limits. Nothing could be more sublime than this vast subterranean apartment, illuminated by flambeaux, which faintly discover its prodigious magnitude, and leave the imagination at liberty to enlarge it indefinitely. After remaining about two hours and a half under ground, I was drawn up again in three minutes with the greatest facility."

* Memoirs of the Courts of Berlin, Dresden, Warsaw, and Vienna.

SALTPETRE (see *Nitre*, CHEMISTRY-*Index*, in this *Suppl.*) is an article of so much importance, and sometimes so difficult to be had, that it is wonderful more attention is not bestowed in endeavouring to discover some easy method to increase the quantity. Such a method has been long practised by the farmers of Appenzell in Switzerland. In so hilly a country, most houses and stables are built on slopes, one side of the edifice resting on the hill, and the other being supported by two strong posts, elevated two or three feet above the ground; so that the air has a free current under the building. Immediately under the stable a pit is dug, usually occupying both in breadth and length the whole space of ground covered by the building; and instead of the clayey earth which is dug out, the pit is filled up with sandy soil. This is the whole process, and all the rest is done by nature. The animal water, which is continually oozing through the planks of the floor, having drenched the earth contained in the pit for the space of two or three years, the latter is emptied, and the saltpetre is refined and prepared in the usual manner.

That manner, however, is not the best; and the French chemists, during the incessant wars occasioned by the revolution, have, for the sake of supplying their armies with gunpowder, turned their attention to the best method of refining saltpetre. The following are directions given for this purpose by Chaptal, Champy, and Bonjour.

The crude saltpetre is to be beaten small with mallets, in order that the water may more easily attack every part of the mass. The saltpetre is then to be put into tubs, five or six hundred pounds in each tub. Twenty *per cent.* of water is to be poured into each tub, and

Saltpetre. and the mixture well stirred. It must be left to macerate or digest until the specific gravity of the fluid ceases to augment. Six or seven hours are sufficient for this last operation, and the water acquires the density of between 25 and 35 degrees. (Sp. gr 1.21, and 1.300, ascertained by Baume's hydrometer. See HYDROMETER, *Suppl.*

The first water must then be poured off, and a second portion of water must be poured on the same saltpetre amounting to 10 *per cent.*; after which the mixture must be stirred up, suffered to macerate for one hour, and the fluid drawn or poured off.

Five *per cent.* of water must then be poured on the saltpetre; and after stirring the whole, the fluid must be immediately drawn off.

When the water is drained from the saltpetre, the salt must be thrown into a boiler containing 50 *per cent.* of boiling water. When the solution is made, it will mark between 66 and 68 degrees of the hydrometer. (Sp. gr. 1.848, and 1.898.)

The solution is to be poured into a proper vessel, where it deposits by cooling about two-thirds of the saltpetre originally taken. The precipitation begins in about half an hour, and terminates in between four and six hours. But as it is of importance to obtain the saltpetre in small needles, because in this form it is more easily dried, it is necessary to agitate the fluid during the whole time of the crystallization. A slight motion is communicated to this liquid mass by a kind of rake; in consequence of which the crystals are deposited in very slender needles.

In proportion as the crystals fall down, they are scraped to the borders of the vessel, whence they are taken with a skimmer, and thrown to drain in baskets placed on tressels, in such a manner that the water which passes through may either fall into the crystallizing vessel, or be received in basons placed underneath.

The saltpetre is afterwards put into wooden vessels in the form of a mill-hopper or inverted pyramid with a double bottom. The upper bottom is placed two inches above the lower on wooden ledges, and has many small perforations through which water may pass to the lower bottom, which likewise affords a passage by one single aperture. A reservoir is placed beneath. The crystallized saltpetre is washed in these vessels with 5 *per cent.* of water; which water is afterwards employed in the solution of saltpetre in subsequent operations.

The saltpetre, after sufficient draining, and being dried by exposure to the air upon tables for several hours, may then be employed in the manufacture of gunpowder.

But when it is required to use the saltpetre in the speedy and immediate manufacture of gunpowder, it must be dried much more strongly. This may be effected in a stove, or more simply by heating it in a flat metallic vessel. For this purpose the saltpetre is to be put into the vessel to the depth of five or six inches, and heated to 40 or 50 degrees of the thermometer (or about 135° of Fahrenheit). The saltpetre is to be stirred for two or three hours, and dried so much that, when strongly pressed in the hand, it shall acquire no consistence, nor adhere together, but resemble a very fine dry sand. This degree of dryness is not required when the powder is made by pounding.

From these circumstances, we find that two saline liquids remain after the operation; (1) the water from the washing; and (2) that from the crystallizing vessels.

We have already remarked, that the washing of the saltpetre is performed in three successive operations, in which, upon the whole, the quantity of fluid made use of amounts to 35 *per cent* of the weight of the crude saltpetre. These washings are established on the principle, that cold water dissolves the muriats of soda, and the earthy nitrats and muriats, together with the colouring principle, but scarcely attacks the nitrat of potash.

The water of these three washings therefore contains the muriat of soda, the earthy salts, the colouring principle, and a small quantity of nitrat of potash; the amount of which is in proportion to that of the muriat of soda, which determines its solution.

The water of the crystallizing vessels contains a portion of the muriats of soda, and of the earthy salts which escaped the operation of washing, and a quantity of nitrat of potash, which is more considerable than that of the former solution.

The waters made use of at the end of the operation, to whiten and wash the crystals deposited in the pyramidal vessel, contain nothing but a small quantity of nitrat of potash.

These waters are therefore very different in their nature. The water of the washings is really a mother water. It must be collected in [illegible], and treated with potash by the known processes. It must be evaporated to 66 degrees (or 1,848 to [illegible]) [illegible] the muriat of soda as it falls. This [illegible] to be saturated with 2 or 3 *per cent.* of potash, [illegible] decanted, and poured i[illegible] where 10 *per cent.* of water is to [illegible] added, to keep the whole of the muriat of soda [illegible]ded.

The waters whic[illegible] thus obtained by treatment of the mother water, may be mixed with the water of the first crystallization. From these the marine salt may be separated by simple evaporation; and the nitrat of potash, which they hold in solution, may be afterwards obtained by cooling.

The small quantity of water made use of to wash and whiten the refined saltpetre, contains nothing but the nitrat of potash: it may therefore be used in the solution of the saltpetre when taken from the tubs.

From this description it follows, that a manufactory for the speedy refining of saltpetre ought to be provided with (1) mallets or rammers for pounding the saltpetre; (2) tubs for washing; (3) a boiler for solution; (4) a crystallizing vessel of copper or lead, in which the saltpetre is to be obtained by cooling; (5) baskets to drain the crystals; (6) a wooden case or hopper for the last washing and draining the saltpetre; (7) scales and weights for weighing; (8) hydrometers and thermometers, to ascertain densities and temperatures; (9) rakes to agitate the liquor in the crystallizing vessel; (10) skimmers to take out the crystals, and convey them to the baskets; (11) syphons or hand pumps to empty the boilers.

The number and dimensions of these several articles must vary according to the quantity of saltpetre intended to be refined.

Saltpetre, Sandarac. GUM-SANDARAC, is said, in the *Encyclopædia*, to

Sandarac, Sanders.

to be produced from a species of juniper. This was long the common opinion; but M. Schousboe has lately proved(A) it to be a mistake The *juniperus communis*, from which many have derived this gum, does not grow in Africa; and Sandarac seems to belong exclusively to that part of the world. The gum sandarac of our shops is brought from the southern provinces of the kingdom of Morocco. About six or seven hundred quintals of it are exported every year from Santa Cruz, Mogador, and Saffy. In the language of the country it is called *el grassa*. The tree which produces it is a *Thuia*, found also by M. Vahl in the kingdom of Tunis. It was made known several years ago by Dr Shaw, who named it *Cypressus fructu quadrivalvi, Equiseti instar articulatis*; but neither of these learned men was acquainted with the economical use of this tree; probably because, being not common in the northern part of Barbary, the inhabitants find little advantage in collecting the resin which exudes from it.

M. Schousboe, who saw the species of *thuia* in question, says that it does not rise to more than the height of twenty or thirty feet at most, and that the diameter of its trunk does not exceed ten or twelve inches. It distinguishes itself, on the first view, from the two other species of the same genus, cultivated in gardens, by having a very distinct trunk, and the figure of a real tree; whereas in the latter the branches rise from the root, which gives them the appearance rather of bushes. Its branches also are [illegible] articulated and brittle. Its flowers, which are not very apparent, shew themselves in April [illegible] which are of a spherical form, ripen in [illegible] branch of th tree is held to the [illegible] to be [illegible] with a [illegible] which contain the resin. When [illegible] the summer months, [illegible] from the trunk and branches, as [illegible] other coniferous trees. This resin is the [illegible] by the inhabitants of the country, and carried to the [illegible] is transported to Europe. It is employed in making some kinds of sealing-wax, and in different sorts of varnish. In 1793 a hundred weight of it cost in Morocco from 13 to 15½ piastres, which make from about L. 3, 5s. to L. 3, 7s. 6d. sterling. The duty on exportation was about 7s. 6d. sterling per quintal.

Sandarac, to be good, must be of a bright-yellow colour, pure and transparent. It is an article very difficult to be adulterated. Care, however, must be taken, that the Moors do not mix with it too much sand. It is probable that a tree of the same kind produces the gum sandarac of Senegal, which is exported in pretty considerable quantities.

SANDERS-RED (see PTEROCARPUS, *Encycl.*) is used as a dye stuff, but generally in a manner which is very disadvantageous. In Crell's Chemical Annals are given, by Mr Vogler, the following directions for dyeing with this wood.

1. Into a solution of tin made with aquafortis (nitric acid), and mixed with three times as much salt water, put clean-washed wool, silk, linen, and cotton. After six hours, take them out, and wash them carefully in three different quantities of clean cold water, wringing them well each time. Let them dry, and then put half the quantity of each article into the spirituous tincture of red sanders, hereafter described in n 6. letting them soak therein, without heat, from half an hour to an hour. To ascertain the superiority of his different processes, the other half of each article must be boiled in the tincture of sanders mixed with water, described in n° 7. a bare quarter of an hour. After being taken out, wrung, and dried in the shade, all of them will be dyed throughout of a fine rich poppy-colour.

2. Take three drams of powdered alum, and dissolve it in twelve ounces of clean hot water. Into this solution, while yet warm, put some well-washed wool, silk, linen, and cotton. After suffering them to remain therein for the space of twelve hours, take them out, wash them well in three quantities of clean cold water (wringing them each time), and dry them. Then steep the half of each article in the cold spirituous tincture of sanders (n° 6.), from half an hour to an hour; and boil the other half of each in the diluted tincture of sanders (n° 7.) for the space of six or seven minutes. After being taken out, wrung, and dried in the shade, they will be found to have acquired a very beautiful and rich scarlet colour.

3. Dissolve three drams of blue vitriol, or vitriol of copper, in twelve ounces of hot water. Steep in this solution, for twelve hours, wool, silk, linen, or cotton; and having sufficiently washed the stuff in clean cold water, immerse the one half of it in the spirituous tincture of sanders (n° 6.), from half an hour to an hour; and boil the other half of each for six or seven minutes in the diluted tincture, n° 7. Being then taken out, wrung, and dried in the shade, as before, they will have acquired a beautiful, rich, bright, crimson colour.

4. Steep wool, silk, linen, and cotton, which has been well washed, during twelve hours, in a solution of three drams of white vitriol, or vitriol of zinc, in twelve ounces of hot water. After being taken out, well washed in clean cold water, and dried, immerse one half of each in the cold spirituous tincture of sanders (n° 6.) and boil the other half in the diluted tincture (n° 7.) as before. When taken out, wrung, and dried, they will be of a fine, rich, deep crimson colour.

5. Dissolve three drams of common green vitriol, or vitriol of iron, in twelve ounces of hot water. Steep well-washed wool, silk, linen, and cotton, in the solution, for the space of twelve hours. When taken out, washed several times in clean cold water, and dried, treat them, as in n° 4. and they will be generally found to be of a fine, rich, deep violet colour; though, on repeating his experiments, our author sometimes found the colour a dark brownish red.

The tincture in which the stuffs are to be dyed must be prepared in the following manner.

6. Take half an ounce of red sanders wood, beat or ground to powder, as it is sold at the colour shops or druggists. Having put it into a large glass bottle, pour upon it twelve ounces of malt spirit or common brandy; then cork the bottle, and set it in a moderately-warm place. In the space of 48 hours, the spirit will have extracted all the colouring matter from the red sanders, and thereby acquired a bright red colour. The bottle

(A) In a Danish Journal, intitled, *The Physical, Medical, and Economical Library*, Part III. 1799.

should be often shaken during the digestion: and the tincture, thus prepared, may be used for dyeing without heat, and without separating the powdered sanders from the liquor. The articles to be dyed (after the application of the proper mordants, n° 1, 2, 3, 4, 5) are to be steeped in the tincture for half an hour, or a whole hour: they are then to be taken out, wrung, and dried in the shade. This tincture does not lose its dyeing quality by age; but dyes substances, after being kept a long time, almost as well as when it is just made. Its colouring power is indeed weakened by the frequent immersion and dyeing of different articles in it; and when that is the case, it must be again digested with some fresh sanders-wood.

7. Mix the spirituous tincture of sanders, just described, with from six to ten times as much clean cold water. The mixture was made by our author without any separation of the colouring particles worth noticing; and in this diluted tincture, the various articles (having their proper mordants first applied, n° 1, 2, 3, 4, 5) were boiled, as before mentioned. Linen and cotton, by being dipped in glue-water, after the application of the mordants, acquire, in this diluted tincture, a much deeper and richer colour.

If a very fine and bright colour be desired, the above spirituous tincture of sanders should not be too old, nor should the digestion be protracted beyond 48 hours; for after that period, the spirit appears to extract brown and yellow colouring particles from the wood. The powder of sanders need not be separated from the diluted tincture which is made use of by boiling; nor is it absolutely necessary to wash the articles in cold water after they are dyed; as the powder which adheres to them may easily be taken off by rubbing and shaking. M. Vogler, however, found it advantageous, after the articles were taken out of the dye, and wrung, to keep them for a few minutes in a cold solution of half an ounce of common salt, and a quarter of an ounce of alum, in 12 ounces of pure water. In this case, they should afterwards be washed several times in clean cold water, then wrung and dried in the shade. By this method the colours are not only more beautiful, but are also more permanent. All the articles of wool, silk, linen, and cotton, which were dyed as is above mentioned, bore perfectly well the test of alkaline ley, soap, and acids; but, by exposure to the open air and the sun, the colours were more easily discharged, especially from linen and cotton.

N. B. Red sanders, by being ground to a fine powder, answers much better for dyeing by this process, than when it is merely cut into small pieces; but it must be remarked, that the powder of red sanders which is sold at the shops is sometimes adulterated, by being mixed with other substances, and moistened with acids. The best kind is not light, but rather heavy; and is not of a dark red colour, but clear and bright.

Goodwin SANDS, famous sand banks off the coast of Kent, lying between the north and south Foreland; and as they run parallel with the coast for three leagues together, at about two leagues and a half distant from it, they add to the security of that capacious road the Downs; for while the land shelters ships with the wind from south-west to north-west only, these sands break all the force of the sea when the wind is at east south-east. The most dangerous wind, when blowing hard on the Downs, is the south-south-west. These sands occupy the space that was formerly a large tract of low ground belonging to Godwyn Earl of Kent, father of King Harold; and which being afterward given to the monastery of St Augustin at Canterbury, the abbot neglecting to keep in repair the wall that defended it from the sea, the whole track was drowned, according to Salmon, in the year 1100, leaving these sands, upon which so many ships have since been wrecked.

SANSANDING, a town in Africa, situated near the banks of the Niger, in Lat. 14° 24′ N. and 2° 23′ W. Long. It is inhabited by Moors and Negroes to the number of from eight to ten thousand. The Negroes are kind, hospitable, and credulous; the Moors are at Sansanding, as everywhere else in the interior parts of Africa, fanatical, bigotted, and cruel.

SAP, or Sapp, in building, as to sap a wall, &c. is to dig out the ground from beneath it, so as to bring it down all at once for want of support.

SAPHAN, in zoology. See Mus, *Encycl.* p. 467.

SAPHIES, a kind of charms, consisting of some scrap of writing, which the credulous Negroes believe capable of protecting them from all evil. The writers of saphies are generally Moors, who sell scraps of the Koran for this purpose to a people who believe not either in the Koran or the prophet. Accordingly, any piece of writing may be sold as a saphie; and Mr Park found the Negroes disposed to place greater confidence in the saphies of a Christian than in those of a Moor. The manner in which these charms are supposed to operate, will be learned [illegible]

Mr Park, being [illegible] near the Niger, and [illegible] hearing that he was a [illegible] of procuring a saphie [illegible] out his walha or writing board [illegible] our author) that he would [illegible] if I would write him a saphie to protect him from wicked men. The proposal was of too great consequence to me to be refused; I therefore wrote the board full from top to bottom, on both sides; and my landlord, to be certain of having the whole force of the charm, washed the writing from the board into a calabash with a little water; and having said a few prayers over it, drank this powerful draught; after which, lest a single word should escape, he licked the board until it was quite dry. A saphie writer was a man of too great consequence to be long concealed: the important information was carried to the Dooty, who sent his son with half a sheet of writing-paper, desiring me to write him a *naphula saphie* (a charm to procure wealth). He brought me, as a present, some meal and milk; and when I had finished the saphie, and read it to him with an audible voice, he seemed highly satisfied with his bargain, and promised to bring me in the morning some milk for my breakfast. Our author contrived to turn this absurd superstition to his own advantage, by writing saphies for his subsistence when his money was exhausted.

SARACOLETS, a Negro nation occupying the lands situated between the rivers of Senegal and Gambia. They are a laborious people, cultivate their lands with care, are plentifully supplied with all the necessaries of life, and inhabit handsome and well built villages; their houses, of a circular form, are for the most part terra-

Saracolets, Saville.

ced; the others are covered with reeds as at Senegal; they are inclosed with a mud wall a foot thick, and the villages are surrounded with one of stone and earth of double that solidity. There are several gates, which are guarded at night for fear of a surprise. This nation is remarkably brave, and it is very uncommon to find a Saracolet slave. They always defend themselves with advantage against their assailants. Such Saracolets as are exposed to sale may be safely purchased, for (excepting when they are at war with the Poules) none are to be met with but such as have been condemned by the laws for some misdemeanour; in such case, these wretches could not escape slavery even by taking refuge in their own country; for they would be restored to their masters, or would be put to death, if the convoy should have failed. The religious principles of this people are nearly allied to Mahometanism, and still more to natural religion. They acknowledge one God, and believe that those who steal, or are guilty of any crime, are eternally punished. They admit a plurality of wives, and believe their souls to be immortal like their own. They think lightly of [illegible]; for as they [illegible] themselves several wives, they are not so unjust as to punish women who [illegible] their favours among several gallants; [illegible] exchange is then permitted, one [illegible] for another, unless she be free, or [illegible] country. In this last case, the French [illegible] the [illegible] of the [illegible]

[illegible]

[illegible] same place [illegible] was a cycle like to that of Meto.

SARRASIN, or SARRAZIN, in fortification, a kind of port-cullis, otherwise called [illegible] hung with ropes over the gate of a town or fortress, to be let fall in case of a surprise.

SAVILLE (Sir Henry), a very learned Englishman, the second son of Henry Saville, Esq; was born at Bradley, near Halifax, in Yorkshire, November the 30th, 1549. He was entered of Merton College, Oxford, in 1561, where he took the degrees in arts, and was chosen fellow. When he proceeded master of arts in 1570, he read for that degree on the Almagest of Ptolemy, which procured him the reputation of a man eminently skilled in mathematics and the Greek language; in the former of which he voluntarily read a public lecture in the university for some time.

In 1578 he travelled into France and other countries; where, diligently improving himself in all useful learning, in languages, and the knowledge of the world, he became a most accomplished gentleman. At his return, he was made tutor in the Greek tongue to Queen Elizabeth, who had a great esteem and liking for him.

Saville.

In 1585 he was made warden of Merton College, which he governed six and thirty years with great honour, and improved it by all the means in his power.—In 1596 he was chosen provost of Eton College; which he filled with many learned men.—James the First, upon his accession to the crown of England, expressed a great regard for him, and would have preferred him either in church or state; but Saville declined it, and only accepted the ceremony of knighthood from the king at Windsor in 1604. His only son Henry dying about that time, he thenceforth devoted his fortune to the promoting of learning. Among other things, in 1619, he founded, in the university of Oxford, two lectures, or professorships, one in geometry, the other in astronomy; which he endowed with a salary of 160l. a-year each, besides a legacy of 600l. to purchase more lands for the same use. He also furnished a library with mathematical books, near the mathematical school, for the use of his professors; and gave 100l. to the mathematical chest of his own appointing: adding afterwards a legacy of 40l. a-year to the same chest, to the university, and to his professors jointly. He likewise gave 120l. towards the new building of the schools, beside several rare manuscripts and printed books to the Bodleian library; and a good quantity of Greek types to the printing-press at Oxford.

After a life thus spent in the encouragement and promotion of science and literature in general, he died at Eton College the 19th of February 1622, in the 73d year of his age, and was buried in the chapel there. On this occasion, the university of Oxford paid him the greatest honours, by having a public speech and verses made in his praise, which were published soon after in 4to, under the title of *Ultima Linea Savilii*.

As to the character of Saville, the highest encomiums are bestowed on him by all the learned of his time: by Casaubon, Mercerus, Meibomius, Joseph Scaliger, and especially the learned Bishop Montague; who, in his *Diatribæ* upon Selden's History of Tythes, styles him, "that magazine of learning, whose memory shall be honourable amongst not only the learned, but the righteous for ever."

Several noble instances of his munificence to the republic of letters have already been mentioned; in the account of his publications many more, and even greater, will appear. These are,

1. Four Books of the Histories of Cornelius Tacitus, and the Life of Agricola; with Notes upon them, in folio, dedicated to Queen Elizabeth, 1581.—2. A View of certain Military Matters, or Commentaries concerning Roman Warfare, 1598.—3. *Rerum Anglicarum Scriptores post Bedam*, &c. 1596. This is a collection of the best writers of our English history; to which he added chronological tables at the end, from Julius Cæsar to William the Conqueror.—4. The Works of St Chrysostom, in Greek, in 8 vols folio, 1613. This is a very fine edition, and composed with great cost and labour. [illegible] preface he says, "that having himself visited, [illegible] years before, all the public and private libraries in Britain, and copied out thence whatever he thought useful to this design, he then sent some learned men into France, Germany, Italy,

Saville. Sauffure.

Italy, and the East, to transcribe such parts as he had not already, and to collate the others with the best manuscripts." At the same time, he makes his acknowledgments to several eminent men for their assistance; as Thuanus, Velserus, Schottus, Casaubon, Ducæus, Gruter, Hoeschelius, &c. In the 8th volume are inserted Sir Henry Saville's own notes, with those of other learned men. The whole charge of this edition, including the several sums paid to learned men, at home and abroad, employed in finding out, transcribing, and collating the best manuscripts, is said to have amounted to no less than 8000l. Several editions of this work were afterwards published at Paris.—5. In 1618 he published a Latin work, written by Thomas Bradwardin, archbishop of Canterbury, against Pelagius, intitled, *De Causa Dei contra Pelagium, et de virtute causarum*; to which he prefixed the life of Bradwardin.—6. In 1621 he published a collection of his own Mathematical Lectures on Euclid's Elements, in 4to.—7. *Oratio coram Elizabetha Regina Oxoniæ habita*, anno 1592. Printed at Oxford in 1658, in 4to.—8. He translated into Latin King James's Apology for the Oath of Allegiance. He also left several manuscripts behind him, written by order of King James; all which are in the Bodleian library. He wrote notes likewise upon the margin of many books in his library, particularly Eusebius's Ecclesiastical History; which were afterwards used by Valesius, in his edition of that work in 1659.—Four of his letters to Camden are published by Smith, among Camden's Letters, 1691, 4to.

SAUSSURE (Horace Benedict de) was born at Geneva in 1740. His father, an intelligent farmer, to whom we are indebted for some memoirs relating to rural economy, resided at Conches, a place situated on the banks of the Arve, at the distance of half a league from Geneva; and this country life, added to an active education, expanded no doubt in young De Sauffure that physical strength so necessary to the naturalist who devotes himself to travel. He repaired daily to town to enjoy the advantage of public instruction; and as he lived at the bottom of Saleve, a mountain which he has since rendered celebrated, he amused himself frequently with ascending its steep and rugged sides. Being thus surrounded by the phenomena of nature, and at the same time aided by study, he conceived a taste for natural history, and avoided the error both of the learned, who form theories without having been out of their closets, and of those farmers who, living too near to Nature, are incapable of admiring her beauties.

His earliest passion was botany: a variegated soil, abundant in plants of different kinds, invites the inhabitant of the banks of the Leman to cultivate that agreeable science. This taste produced an intimacy between De Sauffure and the great Haller. He paid him a visit in the year 1764, during his retreat to Bex; and he relates in his travels how much he admired that astonishing man, who excelled in every part of the natural sciences. De Sauffure was induced also to study the vegetable kingdom, by his connection with Ch. Bonnet, who had married his aunt, and who soon set a just value on the rising talents of his nephew. Bonnet (See his life in this *Suppl.*) was then employed on the leaves of plants. De Sauffure studied these organs of vegetables also, and he published the result of his researches, under the title of Observations on the Bark of Leaves. This small work, which appeared soon after the year 1762, contains new observations on the epidermis of leaves, and in particular on the miliary glands by which they are covered.

About that period, the place of professor of philosophy falling vacant, it was conferred upon De Sauffure, who was then only twenty one years of age. Experience proves, that if premature rewards extinguish the zeal of those who labour merely for themselves, they, on the contrary, strengthen it in those who labour only for truth. At that time the two professors of philosophy at Geneva taught physics and logic alternately. De Sauffure discharged this double task with equal success. He gave to his course of logic a practical, and, as one may say, experimental turn; and his method of teaching, which began by studying the senses to arrive at the general laws of the understanding, announced already an able observer of nature.

Physics, however, were the part for which he had the greatest taste, and which conducted him to the study of chemistry and mineralogy. He then began his travels through the mountains; not now to examine their vegetable productions, but to study the mountains themselves, either in the stones of which they are composed, or the disposition of their masses. Geology, a science which was then scarcely in existence, added charms to his numerous excursions through the Alps; and it was then that the talents of the great philosopher were really displayed. During the first fifteen or twenty years of [illegible] by turns in [illegible] traversing the [illegible] of Geneva. He [illegible] side as far as [illegible] to Piedmont. [illegible] ney to [illegible] volcanoes [illegible] After [illegible] were not [illegible] particular [illegible] of studying nature [illegible] every instrument that [illegible] set out until he had [illegible] and observations he intended to make. He often says in his works that he had found this method exceedingly useful.

In the year 1779 he published the first volume of his Travels through the Alps; which contains a minute description of the environs of Geneva, and an excursion as far as Chamouni, a village at the bottom of Mont Blanc. Philosophers will read there with pleasure the description of his Magnetometer. The more he examined mountains, the more was he sensible of the importance of mineralogy. To study it with advantage, he learned the German language; and it may be seen, in the last volumes of his Travels, how much new mineralogical knowledge he had acquired.

Amidst his numerous excursions through the Alps, and at the time of the political troubles of Geneva in 1782, he found means to make his beautiful experiments on hygrometry, which he published in 1783, under the title of *Essays on Hygrometry*. This work, the best that ever came from his pen, established fully his reputation as a philosopher. We are indebted to him also for the invention of a new hygrometer. Deluc

had

Sauffure. had already invented his whalebone hygrometer; and on that account there arofe between him and De Sauffure a fort of conteft, which degenerated into a pretty violent difpute.

In the year 17[illegible]6 De Sauffure refigned the profeffor's chair, which he had filled for about twenty five years, to his pupil and fellow-labourer Pictet, who difcharged with reputation the duties of an office rendered more difficult by fucceeding fo eminent a philofopher.

When De Sauffure was invited by the ftate to take a fhare in the public education, he made it one of the fubjects of his meditations, and prefented the plan of a reform in the education of Geneva; the tendency of which was, to make young people early acquainted with the natural fciences and mathematics. He even wifhed that their phyfical education fhould not be neglected, and with that view propofed gymnaftic exercifes. This plan, which excited much attention in a city where every one is convinced of the imp[illegible] of education, found admirers and partifans; but the poverty of its pecuniary refources was an obftacle to every impo[illegible] innovation. It [illegible] altering [illegible] blifhed [illegible], and that things might [illegible] the whole. The Genevefe were [illegible] their old fyftem of education; and they [illegible] it had not only proved [illegible] generally amongft [illegible] talents of feveral [illegible] (A).

[illegible] confined to [illegible] the [illegible] who have [illegible]. His [illegible] extenfive [illegible] for [illegible] and [illegible] alfo fome [illegible] on electricity, and a defcription of his electrometer, one of the moft perfect that we have. We are indebted to him alfo for feveral inftruments of meafurement, fuch as his cyanometer, deftined to meafure the degree of the bluenefs of the heavens, which varies according to the elevation of the obferver; his diaphanometer (See Photometer, *Suppl.*), and his anemometer, which, by means of a kind of balance, meafures the force of the wind.

Some years after the publication of the fecond volume of his Travels, De Sauffure was admitted as a foreign affociate of the Academy of Sciences of Paris; and Geneva could then boaft of having two of its citizens in that clafs, which confifted only of feven members. De Sauffure not only did honour to his country; he loved and ferved it. He was the founder of the Society of Arts, to which Geneva is indebted for the high ftate of profperity it has attained within the laft thirty years. He prefided over that fociety till the laft Sauffure. moment of his life; and one of his fondeft wifhes was the prefervation of this ufeful eftablifhment.

In confequence of M. de Sauffure's fatiguing labours in the Council of Two Hundred, of which he was a member, and afterwards in the National Affembly, his health began to be deranged, and in 1794 he was almoft deprived of the total ufe of his limbs by a ftroke of the palfy. However painful his condition then m[illegible] be, his mind ftill preferved its activity; and after that accident he revifed the two laft volumes of his Travels, which appeared in 1796. They contain an account of his excurfions to the mountains of Piedmont and Swifferland, and in particular of his journey to the fummit of Mont Blanc. Thefe volumes, inftead of exhibiting any marks of his malady, prefent an enormous mafs of new facts and obfervations of the utmoft importance to phyfics.

He rendered alfo an important fervice to that fcience by publifhing the *Agenda*, which terminate his fourth volume, and in which that great man, furviving himfelf, conducts the young naturalift through the middle of mountains, and teaches him the method of obferving them with advantage. Thefe *Agenda* are a proof of his genius, and of the ftrength of mind which he retained amidft his fufferings. It was alfo during his illnefs that he directed the experiments made on the height of the bed of the Arve, and that he publifhed Obfervations on the Fufibility of Stones by the Blow-pipe, which were inferted in the *Journal de Phyfique*.

Having gone for the fake of his health to the baths of Plombiers, he ftill obferved the mountains at a diftance, and caufed to be brought to him fpecimens of the ftrata which he perceived in the fteepeft rocks. He had announced that he would conclude his travels with fome ideas on the primitive ftate of the earth; but the more he acquired new facts, and the more he meditated on the fubject, the more uncertain did his opinions become in regard to thofe grand revolutions which preceded the prefent epoch. In general he was a Neptunian; that is to fay, afcribed all the revolutions of our globe to water. He admitted the poffibility of the mountains having been thrown up by elaftic fluids difengaged from the cavities of the earth.

Though the ftate of his health began gradually to become worfe, he ftill entertained hopes of recovery; and the French government having appointed him profeffor of philofophy at the Special School of Paris, he did not defpair of being one day able to fill that office; but his ftrength was exhaufted, a general languor fucceeded the vigour he had always enjoyed, his flow and embarraffed pronunciation no longer correfponded with the vivacity of his mind, and formed a melancholy contraft with the pleafantnefs by which he had been formerly diftinguifhed. It was a painful fpectacle to fee this great man reduced thus to imbecility at an age when meditation is beneficial, and when he might have enjoyed the fruits of his reputation and labours.

In vain did he try, for the re-eftablifhment of his health, all the remedies which medicine, enlightened by the

(A) Abauzit, Cramer, Lhuilier, J. Trembley, &c.

(B) Jalabert, A. Trembley, Bonnet, Lefage, Deluc, Senebier, Prévoft, Pictet, and De Sauffure himfelf.

the physical sciences, could afford—all assistance was useless. The vital power quitted him with slow and painful steps. Towards the beginning of autumn 1798 his decay became more visible, his mind lost all its activity, and on the 22d of March 1799 he terminated his brilliant career, at the age of 59, lamented by a family to whom he was dear—by a country to which he had done honour—and by Europe, the knowledge of which he had extended.

SCALE, in architecture and geography, a line divided into equal parts, placed at the bottom of a map or draught, to serve as a common measure to all the parts of the building, or all the distances and places of the map.

SCALES, in mathematics, see SCALES (*Encycl.*), and likewise *Logarithmic Lines*, under which title are mentioned some improvements by Mr Nicholson on Gunter's scale. These improvements are valuable; and the reader will find a fuller account of them in the first volume of the author's *Philosophical Journal*.

SCANTLING, a measure, size, or standard, by which the dimensions, &c. of things are to be determined. The term is particularly applied to the dimensions of any piece of timber, with regard to its breadth and thickness.

SCAPEMENT, in clock-work, a general term for the manner of communicating the impulse of the wheels to the pendulum. The ordinary scapements consist of the swing-wheel and pallets only; but modern improvements have added other levers or detents, chiefly for the purposes of diminishing friction, or for detaching the pendulum from the pressure of the wheels during part of the time of its vibration. See WATCH Making, in this *Suppl.*

SCARFING, a term in carpentry; by which is meant the joining of two beams of wood together to increase the length: the beams in the joint are indented into one another, as in figures 19, 24, and 25, Plate X. *Supplement.*

SCARLET, a beautiful bright red colour given to cloth, either by a preparation of kermes (See that article in *Suppl.*), or more completely by the American cochineal. Professor Beckmann, in the second volume of his History of Inventions, seems to have established the following conclusions:

1*st*, Scarlet, or the kermes-dye, was known in the East in the earliest ages, before Moses, and was a discovery of the Phoenicians in Palestine, but certainly not of the small wandering Hebrew tribes. 2*d*, *Tola* was the ancient Phoenician name used by the Hebrews, and even by the Syrians; for it is employed by the Syrian translator, Isaiah, chap. i. ver. 18. Among the Jews, after their captivity, the Aramæan word *zehori* was more common. 3*d*, This dye was known also to the Egyptians in the time of Moses; for the Israelites must have carried it along with them from Egypt. 4*th*, The Arabs received the name kermes, with the dye, from Armenia and Persia, where it was indigenous, and had been long known; and that name banished the old name in the East, as the name scarlet has in the West. For the first part of this assertion we must believe the Arabs. 5*th*, Kermes were perhaps not known in Arabia; at least they were not indigenous, as the Arabs appear to have had no name for them. 6*th*, Kermes signifies always *red dye*; and when pronounced short, it becomes *deep red*. Scarlet.

Concerning the origin of the name scarlet, which was in use so early as the 11th century, our author has many conjectures, which we need not transcribe, as he seems not quite satisfied with any of them himself. The following reflections upon the comparative excellence of the ancient and modern scarlet, together with the progress of the art of dyeing that colour, are worthy of notice:

"Of the preparation and goodness of the ancient scarlet we certainly know nothing: but as we find in many old pieces of tapestry of the 11th century, and perhaps earlier, a red which has continued remarkably beautiful even to the present time, it cannot at any rate be denied, that our ancestors extolled their scarlet not without reason. We can, however, venture to assert, that the scarlet prepared at present is far superior, owing principally to the effects of a solution of tin.—This invention may be reckoned amongst the most important improvements of the art of dyeing, and deserves a particular relation.

"The tincture of cochineal alone yields a purple colour, not very pleasant, which may be heightened to the most beautiful scarlet by a solution of tin in aqua-regia (nitro-muriatic acid). This discovery was made as follows: [illegible]nelius Drebbel, who was born at Alkmaar, and died at London in [illegible], having placed in his window an [illegible] of cochineal, made with boiling water, for the [illegible] some aqua-regia d[illegible] cident, which [illegible] purple dye into a most beautiful [illegible] conjectures [illegible] which the [illegible] been dissolved [illegible] of this, changes [illegible] Kuffelar, [illegible] afterwards his [illegible] discovery to perfection, and [illegible] years alone in his dye-house, which gave [illegible] the name of Kuffelar's colour. In the course of time the secret became known [illegible] inhabitant of [illegible] called Gulich, and also to [illegible] a person of the name of Van der Vecht, who t[illegible] to the brothers Gobelins in France. Giles Gobelin, a dyer at Paris, in the time of Francis I. had found out an improvement of the then usual scarlet dye; and as he had remarked that the water of the rivulet Bievre, in the suburbs St Marceau, was excellent for his art, he erected on it a large dye-house; which, out of ridicule, was called *Folie Gobelins*, Gobelin's Folly. About this period, a Flemish painter, whom some name Peter Koek, and others Kloek, and who had travelled a long time in the East, established, and continued to his death in 1650, a manufactory for dyeing scarlet cloth by an improved method. Through the means of Colbert, one of the Gobelins learned the process used for preparing the German scarlet dye from one Gluck, whom some consider as the above-mentioned Gulich, and others as Kloek; and the Parisian scarlet dye soon rose into so great repute, that the populace imagined that Gobelin had acquired his art from the devil. It is well known that Louis XIV. by the advice of Colbert, purchased Gobelin's building from his

Scheme ‖ Scolymus.

his successors in the year 1667, and transformed it into a palace, to which he gave the name of *Hôtel royal des Gobelins*, and which he assigned for the use of first-rate artists, particularly painters, jewellers, weavers of tapestry, and others. After that time the rivulet was no longer called Bievre, but Gobelins. About the year 1643, a Fleming, named Kepler, established the first dye-house for scarlet in England, at the village of Bow, not far from London; and on that account the colour was called, at first, by the English, the *Bow dye*. In the year 1667, another Fleming, named Brewer, invited to England by King Charles II. with the promise of a large salary, brought this art there to great perfection."

SCHEME, a draught or representation of any geometrical or astronomical figure, or problem, by lines sensible to the eye; or of the celestial bodies in their proper places for any moment; otherwise called a diagram.

SCIAGRAPHY, or SCIOGRAPHY, the profile or vertical section of a building; used to shew the inside of it.

SCIAGRAPHY, in astronomy, &c. is a [illegible] used by some authors for the art of finding the hour [illegible] or night, by the shadow of the sun, moon, stars [illegible].

SCIOPTIC, or *Sciopteric Ball*, a sphere or [illegible] wood, with a circular hole or perforation, where a lens is placed. [illegible] it may be [illegible] way, to be used in experiments of the darkened room.

SCOLYMUS [illegible] by Pliny and [illegible] genus of [illegible] others of [illegible] sort of wool [illegible] leaves, [illegible] when [illegible] summer [illegible] milky juice. It was eaten both raw and cooked; and Theophrastus observes, as something very remarkable, that when the plant was in flower, or, as others explain the words, when it had finished blowing, it was most palatable. What renders this circumstance singular is, that most milky roots lose for food their milk, and become unfit to be eaten as soon as they have blown. This is the case with the goat's beard, which is eatable only the first year.

Professor Beckmann has, with much labour and erudition, endeavoured to ascertain what is really the plant which was known to the ancients by the name of *scolymus*. He seems to have proved sufficiently, that it was not the *cactus*, the *carduus*, or the *cinara*; but he has not been able to come to any other conclusion. "Were I appointed or condemned (says he) to form a new Latin dictionary, I should explain the article *scolymus* in the following manner: *Planta composita, capitata. Caulis longus, obsitus foliis spinosis. Radix carnosa, lactescens, nigra, dulcis, edulis. Calix squamis inermibus, disco carnoso, ante efflorescentiam eduli. Semina papposa. Turiones edules.* This description, short as it is, contains every thing that the ancients have said in order to characterise that plant."

Sconces, Scotales.

SCONCES, small forts, built for the defence of some pass, river, or other place. Some sconces are made regular, of four, five, or six bastions; others are of smaller dimensions, fit for passes or rivers; and others for the field.

SCOTALES, were meetings held formerly in England for the purpose of drinking ale, of which the expence was defrayed by joint contribution. Thus the tenants of South Malling in Sussex, which belonged [to] the Archbishop of Canterbury, were, at the keeping of a court, to entertain the Lord or his bailiff with a drinking, or an *ale*; and the stated quotas towards the charge were, that a man should pay three pence halfpenny for himself and his wife, and a widow and a cottager three halfpence. In the manor of Ferring, in the same county, and under the same jurisdiction, it was the custom for the tenants named to make a *scotale* of sixteen pence halfpenny, and to allow out of each sixpence three halfpence for the bailiff.

Common scotales in taverns, at which the clergy were not to be present, are noticed in several ecclesiastical canons. They were not to be published in the church by the clergy or the laity; and a meeting of more than ten persons of the same parish or vicinage was a scotale that was generally prohibited. There were also common drinkings, which were denominated *leet-ale, bride-ale, clerk-ale*, and *church-ale*. To a *leet-ale* probably all the residents in a manorial district were contributors; and the expence of a *bride-ale* was defrayed by the relations and friends of a happy pair, who were not in circumstances to bear the charges of a wedding dinner. This custom prevails occasionally in some districts of Scotland even at this day, under the denomination of a *penny bride-ale*, and was very common fifty or sixty years ago. The *clerk's* ale was in the Easter holidays, and was the method taken to enable clerks of parishes to collect more readily their dues.

Mr Warton, in his History of English Poetry, has inserted the following extract from an old indenture, which shews clearly the design of a *church-ale*. "The parishioners of Elveston and Okebrook, in Derbyshire, agree jointly to brew four ales, and every ale of one quarter of malt, betwixt this and the feast of St John the Baptist next coming; and that every inhabitant of the said town of Okebrook shall be at the several ales. And every husband and his wife shall pay two pence, every cottager one penny; and all the inhabitants of Elveston shall have and receive all the profits and advantages coming of the said ales, to *the use and behoof of the said church of Elveston*."

The *give-ales* were the legacies of individuals; and from that circumstance entirely gratuitous. They seem to have been very numerous, and were generally left to the poor; though, from the largeness of the quantity of ale enjoined to be brewed, it must have been sometimes intended that others were to partake of them. These bequests were likewise, not unfrequently, made to the light or altar of a saint, with directions for singing masses at the obit, trenthal, or anniversary of the testator. Hence, though scotales were generally kept in houses of public resort, the give-ales were sometimes dispensed in the church, and often in the churchyard; by which means "Godde's house (as Sumner says in his Treatise on Gavelkind) was made a tavern of gluttons." Such certainly would be Chalk church, if in it

was

Scowring. was kept the give-ale of William May of that parish; for he ordered his wife to "make in bread six bushels of wheat, and in drink ten bushels of mault, and in cheese twenty pence, to give to poor people for the health of his soull; and he ordered that, after the decease of his wife, his executors and feoffees should continue the custom for evermore."

SCOWRING OF STUFFS, is an art much more generally practised than understood It supposes, says Chaptal. 1st, a knowledge of the different substances capable of staining any kind of cloth; 2d, of the substances to which recourse must be had, in order to make those deposited on the stuff to disappear; 3d, a knowledge of the effects produced on colours by those reagents, which it may be necessary to employ to destroy stains; 4th, a knowledge of the manner in which the cloth is affected by those re agents; 5th, of the art of restoring a colour changed or faded. Of those bodies which occasion spots on different kinds of cloth, some are easily distinguished by their appearance, such as greasy substances; but others have more complex effects, such as acids, alkalies, perspired matter, fruits, urine, &c. Acids redden black, fawn, violet, and puce-colour, and every shade communicated with orchilla-weed, iron, astringents, and every blue except indigo and prussian blue. They render the yellows paler, except that of arnatto, which they change into orange.

Alkalies change to violet the reds produced by Brazil-wood, logwood, and cochineal. They render the greens on woollen cloth yellowish, make yellow brownish, and change the yellow produced by arnatto to aurora. P[illegible] matter produces the same effects as alkalies.

When the spots are produced by simple bodies on stuffs, it is easy to remove them by the means already known. Greasy substances are removed by alkalies, soaps, the yolk of eggs, fat earths; oxyds of iron, by the nitric and oxalic acids; acids by alkalies, and reciprocally. Stains of fruit on white stuffs may be removed by the sulphureous acid, and still better by the oxygenated muriatic acid. But when the spots are of a complex kind, it will be necessary to employ several means in succession. Thus, to destroy the stain of coom from carriage-wheels, after the grease has been dissolved, the oxyd of iron may be removed by the oxalic acid.

As colours are often changed by re-agents, it will be necessary, in order to restore them, that the scowrer should possess a thorough knowledge of the art of dyeing, and how to modify the means according to circumstances. This becomes the more difficult, when it is necessary to reproduce a colour similar to that of the rest of the stuff, to apply that colour only in one place, and often to restore the mordant by which it was fixed, and which has been destroyed, or even the first tint which gave the colour its intensity. It may be readily conceived, that the means to be employed must depend on the nature of the colour and the ingredients by which it was produced; for it is known that the same colour may be obtained from very different bodies. Thus, after an alkali has been employed to destroy an acid spot on browns, violets, blues, poppies, &c. the yellow spot which remains may be made to disappear by a solution of tin; a solution of sulphat of iron restores the colour to brown stuffs which have been galled; acids restore to their former splendour yellows which have been rendered dusky or brown by alkalies; blacks produced by logwood become red by acids; alkalies change these red spots to yellow, and a little of the astringent principle makes them again become black. A solution of one part of indigo in four parts of sulphuric acid, diluted with a sufficient quantity of water, may be employed with success to revive the blue colour of cotton or wool which has been changed. Scarlet may be revived by means of cochineal and a solution of the muriat of tin, &c.

The choice of re-agents is not a matter of indifference. Vegetable acids are preferable; the sulphureous acid, however, may be employed for stains occasioned by fruit; it does not change the blue of silk nor colours produced by astringents; it does not degrade the yellow of cotton. Ammonia succeeds better than fixed alkalies in removing spots produced by acids. It is employed in vapour; its action is speedy, and seldom alters the colour.

The means of removing greasy spots are well known. This effect is produced by alkalies, fullers earth, volatile oils dissolved in alcohol, a heat proper for volatilizing grease, &c. Spots occasioned by ink, rust, or iron-mould of any kind, and all those produced by the yellow oxyd of iron, are removed by the oxalic acid: the colour may be restored by alkalies, or a solution of the muriat of tin. These spots may be removed also by the oxygenated muriatic acid, when they are on white stuffs or paper.

The acid [illegible] alka[illegible] matter, are the [illegible] acids, or even by a weak solu[illegible] When these spots arise from [illegible] in order to destroy [illegible] polychrest composition [illegible] one of the most [illegible] and mix [illegible] with [illegible] four to six eggs; add gradually essence of [illegible] corporate with the whole some [illegible] in such a manner as to form balls of a [illegible] consistence. Moisten the spot; and having rubbed it with these balls, the spot will be removed by washing the stuff. All spots, except iron-mould and ink, may be removed in this manner.

Washing destroys the lustre, and [illegible] a tarnished place disagreeable to the eye; but the lustre may be restored by drawing over the washed place, and in the direction of the pile, a brush moistened in water, impregnated with a little gum. You may then apply a sheet of paper, or a piece of cloth, and a considerable weight, under which the cloth must be left to dry.

Scowring, Scylla.

SCYLLA. Under this title we gave, in the *Encyclopædia*, an account of Scylla and Charybdis, which, though taken from a work which we thought good authority, appears to be far from correct. These places, so famous in the poems of Homer and Virgil, were examined with minute attention by that accurate observer of nature the Abbé Spallanzani; who thus describes Scylla.

"It is a lofty rock, distant twelve miles from Messina, which rises almost perpendicularly from the sea on the shore of Calabria, and beyond which is the small city of the same name. Though there was scarcely any wind, I began to hear, two miles before I came to the rock,

rock, a murmur and noise like a confused barking of dogs, and on a nearer approach readily discovered the cause. This rock, in its lower parts, contains a number of caverns, one of the largest of which is called by the people there *Dragara*. The waves, when in the least agitated, rushing into these caverns, break, dash, throw up frothy bubbles, and thus occasion these various and multiplied sounds. I then perceived with how much truth and resemblance of nature Homer and Virgil, in their personifications of Scylla, had pourtrayed this scene, by describing the monster they drew as lurking in the darkness of a vast cavern, surrounded by ravenous barking mastiffs, together with wolves, to increase the horror.

"Such is the situation and appearance of Scylla: let us now consider the danger it occasions to mariners. Though the tide is almost imperceptible in the open parts of the Mediterranean, it is very strong in the strait of Messina, in consequence of the narrowness of the channel, and is regulated, as in other places, by the periodical elevations and depression of the water. Where the flow or current is accompanied by a wind blowing the same way, vessels have nothing to fear, since they either do not enter the strait, both the wind and the stream opposing them, but cast anchor at the entrance; or, if both are favourable, enter on full sail, and pass through with such rapidity that they seem to fly over the water. But when the current runs from south to north, and the north wind blows hard at the same time, the ship which [illegible] to [illegible] the strait with the wind in its [illegible] as resisted by the [illegible] and, [illegible] by two forces in contrary directions, is at length dashed on the rock of Scylla, [illegible] the neighbouring sands; unless the [illegible] necessary for his preservation. [illegible] in case of such accidents, 24 of the strongest [illegible] and most experienced sailors, well acquainted with the place, are stationed night and day along the shore of [illegible]; who, at the report of guns fired as signals of distress from any vessel, hasten to its assistance, and tow it with one of their light boats. The current, where it is strongest, does not extend over the whole strait, but winds thro' it in intricate meanders, with the course of which these men are perfectly acquainted, and are thus able to guide the ship in such a manner as to avoid it. Should the pilot, however, confiding in his own skill, contemn or neglect this assista[illegible] his ability or experience, he would run the most imminent risk of being shipwrecked. In this agitation and conflict of the waters, forced one way by the current, and driven in a contrary direction by the wind, it is useless to throw the line to discover the depth of the bottom, the violence of the current frequently carrying the lead almost on the surface of the water. The strongest cables, though some feet in circumference, break like small cords. Should two or three anchors be thrown out, the bottom is so rocky that they either take no hold; or, if they should, are soon loosened by the violence of the waves. Every expedient afforded by the art of navigation, though it might succeed in saving a ship in other parts of the Mediterranean, or even the tremendous ocean, is useless here. The only means of avoiding being dashed against the rocks, or driven upon the sands in the midst of this furious contest of the winds and waves, is to have recourse to the skill and courage of these Messinese seamen."

Scylla.

Charybdis is situated within the strait, in that part of the sea which lies between a projection of land named *Punta Secca*, and another projection on which stands the tower called *Lanterna*, or the light-house, a light being placed at its top to guide vessels which may enter the harbour by night. Every writer, who has hitherto described Charybdis, has supposed it to be a whirlpool; but this is a mistake, as Spallanzani has completely proved, by ascertaining what it really is.

"Charybdis is distant from the shore of Messina about 750 feet, and is called by the people of the country *Calofaro*, not from the agitation of the waves, as some have supposed, but from καλος and φαρος; that is, *the beautiful tower*, from the light-house erected near it for the guidance of vessels. The phenomenon of the Calofaro is observable when the current is descending; for when the current sets in from the north, the pilots call it the *descending rema*, or current; and when it runs from the south, the *ascending rema*. The current ascends or descends at the rising or setting of the moon, and continues for six hours. In the interval between each ascent or descent, there is a calm which lasts at least a quarter of an hour, but not longer than an hour. Afterwards, at the rising or setting of the moon, the current enters from the north, making various angles of incidence with the shore, and at length reaches the Calofaro. This delay sometimes continues two hours; sometimes it immediately falls into the Calofaro; and then experience has taught that it is a certain token of bad weather."

When our author observed Charybdis from the shore, it appeared like a group of tumultuous waters; which group, as he approached, became more extensive and more agitated. He was carried to the edge, where he stopped some time to make the requisite observations; and was then convinced, beyond the shadow of a doubt, that what he saw was by no means a vortex or whirlpool.

Hydrologists teach us, that by a whirlpool in a running water we are to understand that circular course which it takes in certain circumstances; and that this course or revolution generates in the middle a hollow inverted cone, of a greater or less depth, the internal sides of which have a spiral motion. But Spallanzani perceived nothing of this kind in the Calofaro. Its revolving motion was circumscribed to a circle of at most 100 feet in diameter; within which limits there was no incurvation of any kind, nor vertiginous motion, but an incessant undulation of agitated waters, which rose, fell, beat, and dashed on each other. Yet these irregular motions were so far placid, that nothing was to be feared in passing over the spot, which he did; though their little bark rocked very much from the continual agitation, so that they were obliged constantly to make use of their oars to prevent its being driven out of the Calofaro. Our author threw substances of different kinds into the stream. Such as were specifically heavier than the water sunk, and appeared no more; those which were lighter remained on the surface, but were soon driven out of the revolving circle by the agitation of the water.

Though from these observations he was convinced that there was no gulph under the Calofaro, as otherwise

Scylla, Sea-sickness.

wise there would have been a whirlpool, which would have carried down into it the floating substances; he determined to sound the bottom with the plummet, and found its greatest depth did not exceed 500 feet. He was likewise informed, to his no small surprise, that beyond the Calofaro, towards the middle of the strait, the depth was double.

When the current and the wind are contrary to each other, and both in their greatest violence, especially when the scilocco, or south wind, blows, the swelling and dashing of the waves within the Calofaro is much stronger, more impetuous, and more extensive. It then contains three or four small whirlpools, or even more, according to the greatness of its extent and violence. If at this time small vessels are driven into the Calofaro by the current or the wind, they are seen to whirl round, rock, and plunge, but are never drawn down into the vortex. They only sink when filled with water, by the waves beating over them. When vessels of a larger size are forced into it, whatever wind they have they cannot extricate themselves; their sails are useless; and after having been for some time tossed about by the waves, if they are not assisted by the pilots of the country, who know how to bring them out of the course of the current, they are furiously driven upon the neighbouring shore of the Lanterna, where they are wrecked, and the greater part of their crews perish in the waves.

From these facts, the classical reader will perceive, that the ancient descriptions of Charybdis are by no means so accurate as those of Scylla. The saying, however, which became proverbial among the ancients, viz. that "he who endeavours to avoid Charybdis, dashes upon Scylla," is, in a great measure, true. If a ship be extricated from the fury of Charybdis, and carried by a strong southerly wind along the strait towards the northern entrance, it will indeed pass out safely; but should it meet with a wind in a nearly opposite direction, it would become the sport of both these winds, and, unable to advance or recede, be driven in a middle course between their two directions, that is to say, full upon the rock of Scylla, if it be not immediately assisted by the pilots. It is likewise observed, that in these hurricanes a land wind frequently rises, which descends from a narrow pass in Calabria, and increases the force with which the ship is impelled towards the rock.

SEA-SICKNESS is a disorder which has been but little treated of, notwithstanding the frequency of its occurrence, and the irksomeness and distress to which the patient is subjected during its continuance. It has been found to be very beneficial in several diseases, among which the principal are asthmatic and pulmonary complaints; and there are very few instances of its being attended with fatal consequences. The sea-sickness seems to be a spasmodic affection of the stomach, produced by the alternate pressure and recess of the contents of that viscus against its lower internal surface, according as the rise and fall of the ship opposes or recedes from the action of gravity.

The seas in which this disorder attacks the passenger with the greatest violence, are those where the waves have long uninterrupted freedom of action; of course, bays, gulphs, and channels, may be navigated with less inconvenience, as the waves, meeting with more frequent resistance, and the repercussion being considerably stronger, the vessel does not experience that gentle uniform vacillation which sickens the stomach, and renders the head giddy. By the same argument, a person feels less inconvenience from the disorder on the wide ocean in a small vessel, on which the slightest motion of the waves makes a strong impression. He is likewise less exposed to it in a very large vessel, as in a ship of the line, or a large merchantman deeply laden; as the waves, in this case, scarcely affect the vessel. It is in ships of the middling size, and which carry but a light cargo, that the passenger suffers most from the sea sickness. It has been observed, that this disorder affects people in years less than young persons; those of a dark less than those of a fair complection, and that it seldom attacks infants. The duration is not limited to any fixed period of time; with some it lasts only a few days, with others weeks, months, and even during the whole course of the voyage. The sooner it takes place after embarkation, the greater probability is there of its continuance. It does not always cease immediately on landing, but has been known, in some cases, to continue for a considerable time. Even the oldest and most skilful seamen have experienced a relapse, especially if they have quitted the sea service for a long term of years.

There have been ma[illegible] recommended for mitigating, if not entirely [illegible]g, this disorder; among which the following seem the [illegible] effic[illegible]

1. Not to go on board [illegible] eating; and, w[illegible] to eat in any great quantity at any [illegible] e meal.

2. To [illegible] as conveniently [illegible] at the pumps, [illegible] indolent and slothful passengers [illegible] from the disorder.

3. To keep much upon deck, even in stormy and rainy weather, as the sea breeze is less liable to affect the stomach than the fluctuated air of the cabin, which is frequently rendered infectious for want of sufficient circulation.

4. Not to watch the motion of the waves, especially when strongly agita[illegible] with tempest.

5. To avoid carefully all employment which harass the mind, as reading, study, meditation, and gaming; and, on the other hand, to seek every opportunity of mirth and mental relaxation.

6. To drink occasionally carbonic acids, as the froth of strong fermented beer, or wine mixed with Seltzer water, and fermented with pounded sugar, or a glass of Champaign.

7. It will be found of great service to take the acid of sulphur dulcified, dropped upon lump sugar, or in peppermint-water; or ten drops of sulphureous ether.

With regard to eating, it is advisable to be very sparing, at least not to eat much at one meal. The proper diet is bread and fresh meat, which should be eaten cold with pepper. All sweet favoured food should be carefully avoided; and the passenger should refrain from fat, but especially from all meat that is in the least degree tainted. Even the odour of flowers is very pernicious; for which reason, it is not expedient to examine marine productions, as these generally have a nauseating smell. The fumes of vinegar may be inhaled with great benefit. The drink should consist of

tart wines, lemonade, or Seltzer water, but never of common water. The passenger would do well to drink little and often. As experience has proved, that an accidental diarrhœa has frequently relieved the patient from the sea-sickness, it will be prudent to follow the clue of nature, and take a gentle laxative, or, if circumstances will permit, a clyster of salt water and Venice soap, which is the more necessary, as sea-faring people are liable to obstructions. It will further be found useful to apply to the pit of the stomach a tonic anodyne antispasmodic emplastrum, spread upon leather, and covered with linen.

Where the above preventives have not been employed, or have not succeeded in securing the passenger from the sea-sickness, he may, however, experience considerable relief from the following remedies:

If symptoms of vomiting appear, they may frequently be remedied by the patient prostrating himself in a horizontal position, upon the back or belly, and lying perfectly still. We would recommend likewise a gentle compression of the abdomen. But if the fits of vomiting are too violent to be repressed, in that case, it is best to promote them by a strong dose of salt-water; an expedient, however, which must not be too often repeated, as it [illegible] more to weaken the stomach. When the emetic takes effect, let the patient bend his body, advancing his knees towards his breast, and support his head against a firm [illegible] resting place. He must be particularly careful [illegible] his garters and cravat, as this precaution will secure him from the risk of a rupture, and from the ill effects of the blood rushing violently towards the head and breast.

After the [illegible] has subsided, its return may be [illegible] of repose, and even [illegible] time. Let the patient choose a cool [illegible] remembering to keep himself warm and well covered, as perspiration is highly salutary. But he must not indulge in too long sleep during the day-time, as this induces torpidness. In the morning he should constantly take a gargle of sugar dissolved in vinegar. Let him eat often, but sparingly; and if he can content himself with a dish of chocolate, coffee, or strong tea, he will reap still greater benefit. He should never drink water in its pure elementary state, but mix it with brandy, vinegar, or wine. In the morning, instead of brandy, he may take a glass of wine, with an infusion of orange peel, gentian root, or peruvian bark (*quinquina*). A glass of punch taken occasionally will prove of very essential service, as it promotes perspiration.

Persons in the habit of smoking, will find a pleasant and salutary companion in the pipe; but those who are not accustomed to it will be sufferers by taking to the practice.

In conclusion, it is proper to add, that warm clothing, flannel shirts, trowsers, caps, &c. are efficacious remedies against excessive expectoration, and all other symptoms of this terrible disorder.

SECTOR of a Sphere, is the solid generated by the revolution of the sector of a circle about one of its radii; the other radius describing the surface of a cone, and the circular arc a circular portion of the surface of the sphere of the same radius. So that the spherical sector consists of a right cone, and of a segment of the sphere having the same common base with the cone. And hence the solid content of it will be found by multiplying the base or spherical surface by the radius of the sphere, and taking a third part of the product.

Sector of an ellipse, or *of an hyperbola*, &c. is a part resembling the circular sector, being contained by three lines, two of which are radii, or lines drawn from the centre of the figure to the curve, and the intercepted arc or part of that curve.

SEEDS, Preservation of, in a state fit for vegetation, is a matter of great and general importance, because, if it can be accomplished, it will enable us to rear many useful plants in one country which are there unknown, being indigenous only in others at a great distance from it. There is a letter on this subject in the 16th volume of the *Transactions of the Society of Arts*, &c. from which we shall extract what is fit for our purpose.

"Many years ago (says the author), having observed some seeds which had got accidentally amongst raisins, and that they were such as are generally att[illegible]ed difficulty to raise in England after coming in the way from abroad, I sowed them in pots, within ming; and as all of them grew, I commissi[illegible] sons, who were then abroad, to pack up all [illegible] seeds they could procure in absorbent paper, some of them surrounded by raisins, and others brown moist sugar; concluding that the former seeds had been preserved by a peculiarly favourable state of moisture thus afforded them. It occurred, likewise, that as many of our common seeds, such as clover, charlock, &c. would lie dormant for ages with[illegible] the earth, well preserved for vegetation whenever they might happen to be thrown to the surface, and exposed to the atmosphere, so these foreign seeds might be equally preserved, for many months at least, by the kindly covering and genial moisture that either raisins or sugar afforded them: and this conjecture was really fulfilled, as not one in twenty of them failed to vegetate, when those of the same kinds, that I ordered to be sent lapped in common parcels, and forwarded with them, would not grow at all. I observed, upon examining them all before they were committed to the earth, that there was a prevailing dryness in the latter, and that the former looked fresh and healthy, and were not in the least infested by insects, as was the case with the others. It has been tried repeatedly to convey seeds (of many plants difficult to raise) closed up in bottles, but without success; some greater proportion of air, as well as a proper state of moisture, perhaps, being necessary. I should also observe, that no difference was made in the package of the seeds, respecting their being kept in husks, pods, &c. so as to give those in raisins or sugar any advantage over the others, all being sent equally guarded by their natural teguments."

SEGALIEN, the name given by Europeans to a large island separated by a narrow channel from the coast of Chinese Tartary, and called by the natives *Tchoka*, and by the Chinese *Oku-Jesso*. It lies between the 46th and 54th degrees of north latitude, but its breadth from east to west is not known. Indeed hardly any thing about it was known till the year 1787, that M. La Perouse penetrated almost to the bottom of the channel which separates it from the continent, and which grew so very shallow as he advanced northward

that,

Segalien. that, in all probability, the island will soon become a peninsula. The French frigates came to anchor in different bays on the coast of Segalien; and the finest of these bays, to which the Commodore gave the name of *Baie d'Estaing*, is situated in 48° 59′ N. Lat. and 140° 32′ Lon. East from Paris.

La Perouse and M. Rollin, the surgeon of his ship, both describe the natives of this island as a worthy and intelligent people. Of the presents which were made to them, they seemed to set a value only on such as were useful. Iron and stuffs prevailed over every thing; they understood metals as well as their guests, and for ornament preferred silver to copper, and copper to iron. They make use of looms, which, though small, are very complete instruments; and by means of spindles they prepare thread of the hair of animals, of the bark of the willow, and the great nettle, from which they make their stuffs. They are of a moderate size, squat, and strong built, with the muscles of their bodies very exactly defined: their common height is five feet, and the greatest does not exceed five feet four inches; but men of this size are very uncommon among them. They have all a large head, and a broader and more rounded face than Europeans; their countenance is animated and agreeable, though, upon the whole, it is destitute of that regularity and grace which we esteem so essential to beauty: they have large cheeks, a short nose rounded at its extremity, with very broad nostrils: their eyes are lively, of a moderate size, for the most part black, though some have blue ones among them: their eyebrows are bushy, their mouth of the common size, their voice is strong, their lips are rather thick, and of a dull red: M. Rollin remarked, that in several the upper lip was tattoed, and tinged of a blue colour: these, as well as their eyes, are capable of every variety of expression: their teeth are white, even, and of the usual number; their chin is rounded and a little advancing: their ears are small: they bore and wear in them glass ornaments or silver rings.

The women are not so large as the men, and are of a more rounded and delicate figure, though there is but little difference between the features of their faces. Their upper lip is tattoed all over of a blue colour, and they wear their hair long and flowing: their dress hardly differs from that of the men; the colour of the skin in both sexes is tawny, and that of their nails, which they suffer to grow to a great length, is a shade darker than that of Europeans. These islanders are very hairy, and have long beards, which gives, especially to the old men, a grave and venerable air: these last appear to be held in much respect by the younger part of the inhabitants. The hair of their head is black, smooth, and moderately strong; in some it is of a chesnut colour: they all wear it round, about six inches long behind, and cut into a brush on the top of their head and over the temples.

Their clothing consists of a kind of surtout which wraps over before, where it is fastened by little buttons, strings, and a girdle placed above the haunches. This surtout is made of skin or quilted nankeen, a kind of stuff that they make of willow bark: it generally reaches to the calf of the leg, and sometimes even lower, which for the most part renders the use of drawers unnecessary: some of them wear seal skin boots, the feet of which, in form and workmanship, resembles the Chinese shoe but the greater number of them go bare-footed and bare-headed: a few indeed wear a bandage of bear-skin round the head; but this is rather as an ornament than a defence against the weather. Segalien.

Like the lower classes of the Chinese, they all wear a girdle, to which they hang their knife as a defence against the bears, and several little pockets, into which they put their flint and steel, their pipe, and their box of tobacco; for they make a general practice of smoking.

Their huts are sufficient to defend them against the rain and other inclemencies of the air, but are very small in proportion to the number of the inhabitants which they contain. The roof is formed of two inclined planes, which are from ten to twelve feet high at their junction, and three or four on the sides: the breadth of the roof is about fifteen feet, and its length eighteen: these cabins are constructed of frame work, strongly put together, the sides being filled up with the bark of trees, and the top thatched with dry grass in the same manner as our cottages are.

On the inside of these houses is a square of earth raised about six inches above the ground, and supported on the sides by strong planking; on this they make the fire: along the sides of the apartment are benches twelve or fifteen inches high, which they cover with mats, on which they sleep.

The utensils that they employ in cooking their food consist of an iron pot, shells, vessels made of wood and birch bark, of various shapes and workmanship; and, like the Chinese, they take up their food with little sticks: they have generally two meals in the day, one at noon, and the other in the evening.

The habitations in the south part of the island are much better built and furnished, having for the most part planked floors: our author saw in them some vessels of Japan porcelain, on which the owners appeared to set great value, probably because they are not to be procured but with great trouble and at considerable expence. They cultivate no kind of vegetable, living only on dried and smoked fish, and what little game they take by hunting.

Each family has its own canoe, and implements for fishing and hunting. Their arms are bows, javelins, and a kind of spontoon, which they use principally in bear-hunting. By the side of their houses are the magazines, in which they lay up the provision which they have prepared and collected during summer for their winter subsistence. It consists of dried fish, and a considerable quantity of garlic and wild celery, angelica, a bulbous root which they call *apé*, better known under the name of the yellow lily of Kamtschatka, and fish oil, which they preserve in the stomachs of bears, and other large animals. These magazines are made of planks, strongly and closely put together, raised above the ground on stakes about four feet high.

Dogs are the only domestic animals belonging to the natives of Tchoka; they are of a middling size, with shaggy hair, pricked ears, and a sharp long muzzle; their cry is loud and not savage.

These people, who are of a very mild and unsuspecting disposition, appear to have commercial intercourse with the Chinese by means of the Mantchou Tartars, with the Russians to the north of their island, and the Japanese to the south: but the articles of trade are of

no

no great consequence, consisting only of a few furs and whale oil. This fish is caught only on the southern coast of the island. Their mode of extracting the oil is by no means economical; they drag the whale on shore on a sloping ground, and suffering it to putrify, receive in a trench, at the foot of the slope, the oil, which separates spontaneously.

The island is well wooded, and mountainous towards the centre, but is flat and level along the coast, the soil of which appears admirably adapted to agriculture: vegetation is extremely vigorous here; forests of pine, willow, oak, and birch, cover nearly the whole surface. The sea abounds with fish, as well as the rivers and brooks, which swarm with salmon and trout of an excellent quality. The weather is, in general, foggy and mild. All the inhabitants have an air of health and strength, which they retain even to extreme old age; nor did our author observe among them any instance of defective organization, or the least trace of contagious or eruptive disorders.

SEGMENTS, LINE OF, are two particular lines, so called on Gunter's sector. They lie between the lines of sines and superficies, and are numbered with 5, 6, 7, 8, 9, 10. They represent the diameter of a circle, so divided into 100 parts, as that a right line drawn through those parts, and perpendicular to the diameter, shall cut the circle into two segments, the greater of which shall have [illegible] to the whole circle, as the parts on [illegible] to 100.

SEGO, the [illegible] of the kin[illegible] of Bambarra in Africa, is [illegible] banks of the Niger, in 14° 4' N[illegible] It consists, properly s[illegible] two on the northern [illegible], and Sego Boo; and [illegible] Sego Soo Korro, and [illegible] surrounded with high mud-walls; the houses are built of clay, of a square form, with flat roofs; some of them have two stories, and many of them are whitewashed. Besides these buildings, Moorish mosques are seen in every quarter; and the streets, though narrow, are broad enough for every useful purpose in a country where wheel carriages are entirely unknown. Mr Park informs us, that from the best inquiries that he could make, he has reason to believe that Sego contains altogether about thirty thousand inhabitants. The King of Bambarra constantly resides at Sego See Korro; he employs a great many slaves in conveying people over the river, and the money they receive (though the fare is only ten kowrie shells for each individual) furnishes a considerable revenue to the king in the course of a year. The canoes are of a singular construction, each of them being formed of the trunks of two large trees, rendered concave, and joined together, not side by side, but endwise; the junction being exactly across the middle of the canoe: they are therefore very long and disproportionably narrow, and have neither decks nor masts; they are, however, very roomy; for our author observed in one of them four horses, and several people, crossing over the river. The view of this extensive city; the numerous canoes upon the river; the crowded population, and the cultivated state of the surrounding country, formed altogether a prospect of civilization and magnificence which he little expected to find in the bosom of Africa.

He met not, however, in Sego with that hospitality which he had experienced in some other African towns. The Moors, who abound in it, and whose bigotry renders them the implacable enemies of every white man suspected of being a Christian, contrived to persuade the king that it was for no good purpose he had come into the territories of Bambarra. He was therefore ordered to take up his residence at a village a little distant, without being admitted into the royal presence. Even there, so strong was the prejudice that had been excited against him, no person would admit him into his house. About sunset, however, as he was preparing to pass the night in the top of a tree, that he might not be in danger of being torn to pieces by wild beasts, a poor Negro woman conducted him to her hut, dressed a fine fish for his supper, and furnished him with a mat to sleep on. She then called to the female part of her family, who had stood gazing on him all the while with fixed astonishment, to resume their task of spinning cotton; in which they continued to employ themselves great part of the night. They lightened their labour by songs; one of which was composed extempore, for our author was himself the subject of it. It was sung by one of the young women, the rest joining in a sort of chorus. The air was sweet and plaintive, and the words, literally translated, were these—"The winds roared, and the rains fell.—The poor white man, faint and weary, came and sat under our tree.—He has no mother to bring him milk; no wife to grind his corn. *Chorus*. Let us pity the white man; no mother has he", &c. &c. "Trifling (says Mr Park) as this recital may appear to the reader, to a person in my situation the circumstance was affecting in the highest degree."

Having remained three days in this village, he was dismissed on the fourth, after receiving from the king 5000 kowries, to enable him to purchase provisions in the course of his journey. Though this sum amounted only to one pound sterling, so cheap are the necessaries of life in Bambarra, that it was sufficient to purchase provisions for himself, and corn for his horse, for fifty days.

SELL, in building, is of two kinds, viz. *Ground Sell*, which denotes the lowest piece of timber in a wooden building, and that upon which the whole superstructure is raised; and *Sell of a Window*, or *of a Door*, which is the bottom piece in the frame of them, upon which they rest.

SENN, a kind of itinerant cowkeeper in Switzerland, particularly in the canton of Appenzell. These men do not grow so much hay themselves as they require for their cattle during the winter season, and some of them have no grass lands at all. To supply this deficiency, they employ agents throughout the canton, who are to inform them where good hay may be obtained, which farmers made it in favourable weather, &c. and then the Senn, or the great cowkeeper, who is in want of fodder, makes his agreements for the winter with the wealthier farmers, to whom he successively drives his cattle as soon as they return from grass. Thus the itinerant Senn, with his cows, often visits five different places during the winter season. He who sells the hay furnishes the Senn not only with stabling for his beasts, but boards and lodges him as well as his whole family. In return, the Senn, besides paying the stipulated price for the hay, allows to his host as much milk, whey, and *zieger* (a kind of lean cheese) as may be

Senn. be used in the house, and leaves him also the manure of his cows. In the middle of April, when Nature revives, the Senn again issues forth with his herd to the meadows and fertile Alps, which he rents for the summer. Thus the life of these men is a constant migration, affording the most pleasing variety, and blessing them with health, content, and cheerfulness; but they had not been then cursed with French fraternity.

Fine cattle are the pride of the cowkeeper who inhabits the Alps:—but, not satisfied with their natural beauty, he will likewise please his vanity. He adorns his best cows with large bells suspended from broad thongs; and the expence in such bells is carried even to a luxurious excess. Every Senn has an harmonious set of at least two or three bells, chiming in with the famous *ranz des vaches* (A). The inhabitants of the Tyrol bring a number of such bells, of all sizes, to every fair kept in the canton of Appenzell. They are fixed to a broad strap, neatly pinked, cut out, and embroidered; which is fastened round the cow's neck by means of a large buckle. A bell of the largest size measures upwards of a foot in diameter, is of an uniform width at top, swells out in the middle, and tapers towards the end. It costs from forty to fifty gilders; and the whole peal of bells, including the thongs, will sometimes be worth between 140 and 150 gilders, while the whole apparel of the Senn himself, when best attired, does not amount to the price of twenty gilders. The finest black cow is adorned with the largest bell, and those next in appearance have two smaller. These ornaments, however, are not worn on every day, but only on solemn occasions, viz. when, in the spring, they are driven up the Alps, or removed from one pasture to another; or when they descend in the autumn, or travel in the winter to the different farms, where their owner has contracted for hay. On such days, the Senn, even in the depth of winter, appears dressed in a fine white shirt, of which the sleeves are rolled up above the elbow; neatly embroidered red braces keep up his yellow linen trowsers, which reach down to the shoes; a small leather cap, or hat, covers his head; and a new milk bowl, of wood skilfully carved, hangs across the left shoulder. Thus arrayed, the Senn precedes singing the *ranz des vaches*, and followed by three or four fine goats; next comes the handsomest cow with the great bell; then the two other cows with smaller bells; and these are succeeded by the rest of the cattle walking one after another, and having in their rear the bull with a one-legged milking stool hanging on his horns; the procession is closed by a *traineau*, or sledge, on which are placed the implements for the dairy. It is surprising to see how proud and pleased the cows stalk forth when ornamented with their bells. Who would imagine that even these animals are sensible of their rank, nay, touched with vanity and jealousy? If the leading cow, who hitherto bore the largest bell, be deprived of her honours, she very plainly manifests her grief at the disgrace, by lowing incessantly, abstaining from food, and growing lean. The happy rival, on whom the distinguishing badge of superiority has devolved, experiences her marked vengeance, and is butted, wounded, and persecuted by her in the most furious manner; until the former either recovers her bell, or is entirely removed from the herd. However singular this phenomenon may appear, it is placed beyond all doubt by the concurring testimony of centuries.

Serrishtehdar || Shadows.

The cows, when dispersed on the Alps, are brought together by the voice of the Senn, who is then said to *allure* them (*locken*). How well the cattle distinguish the note of their keeper appears from the circumstance of their hastening to him, though at a great distance, whenever he begins to hum the *ranz des vaches*. He furnishes that cow which is wont to stray farthest with a small bell, and knows by her arrival that all the rest are assembled.

SERRISHTEHDAR, in Bengal, keeper of records or accounts.

SEVEN STARS, a common denomination given to the cluster of stars in the neck of the sign Taurus, the bull, properly called the *Pleiades*. They are so called from their number seven which appear to the naked eye, though some eyes can discover only six of them; but by the help of telescopes there appears to be a great multitude of them.

SEZAWUL, in Bengal, an officer deputed occasionally to enforce the due payment of the revenue.

SHADOWS (COLOURED), a curious [illegible] nomenon, which was observed a considerab[illegible] number of years ago, by Professor [illegible] of Vienna, and more lately by Count [illegible] the discovery wh[illegible] light [illegible] of which the read[illegible] under the titles LAMP and [illegible] in this *Suppl.* "De[illegible]strous (says he) of comparing the intensity of the light of a clear blue sky by day with that of a common wax candle, I darke[illegible] room, and letting the day-light from the north, coming thro' a hole near the top of the window-shutter, fall at an angle of about 70° upon a sheet of very fine white paper, I placed a [illegible] ax-candle in such a position that its rays [illegible] upon the same paper, and, as near as I could [illegible]s, in the line of reflection of the rays of day-light [illegible]; when, interposing a cylinder of wood, [illegible]alf an inch in diameter, before the centre of [illegible], and at the distance of about two inches from its surface, [illegible] much surprised to find that the two shadows p[illegible] by the cylinder upon the paper, instead of being merely shades without colour, as I expected; the one of them, that which, corresponding with the beam of day-light, was illuminated by the candle, was yellow; while the other, corresponding to the light of the candle, and consequently illuminated by the light of the heavens, was of the most beautiful blue that it is possible to imagine. This appearance, which was not only unexpected, but was really in itself in the highest degree striking and beautif[illegible].

(A) This famous pastoral song is never sung by the cowherds with words to it: all the tones of it are simple, and mostly formed within the throat. Hence the tune produces very little or no motion of the jawbones, and its sounds do not resemble those which commonly issue from the human throat, but rather seem to be the tones of some wind instrument; particularly as scarcely any breathing is perceived, and as the cowherds sometimes sing for minutes together without fetching breath.

beautiful, I found upon repeated trials, and after varying the experiment in every way I could think of, to [illegible] that it is absolutely impossible to produce two shadows at the same time, from the same body, the one answering to a beam of day light, and the other to the light of a candle or lamp, without these shadows being coloured, the one yellow, and the other blue.

"If the candle be brought nearer to the paper, the blue shadow will become of a deeper hue, and the yellow shadow will gradually grow fainter; but if it be removed farther off, the yellow shadow will become of a deeper colour, and the blue shadow will become fainter; and the candle remaining stationary in the same place, the same varieties in the strength of the tints of the coloured shadows may be produced merely by opening the window-shutter a little more or less, and rendering the illumination of the paper, by the light from without, stronger or weaker. By either of these means, the coloured shadows may be made to [illegible] through all [illegible] gradations of [illegible] des, from the deepest to the lightest [illegible] vice [illegible] and it is not a little amusing to see [illegible] shadow [illegible] lowing with all the brilliancy of the purest and most [illegible] colours, then passing suddenly through all the varieties of shade, preserving in all the most perfect purity of tint, growing stronger and fainter, and vanishing and returning at command."

With respect to the cause of the colours of these shadows, there is no doubt [illegible] but they arise from the different qualities of the light by which they are illuminated [illegible] they are produced, does not [illegible] de[illegible] philosopher, [illegible] shadows which [illegible] accounted for by Professor [illegible] Co[illegible]

SHAGREEN, or CHAGRIN, [illegible] a kind of grained leather [illegible] process of preparing which, we gave the best account that we could then find in the *Encyclopaedia*. That account, however, as we learn from Professor Pallas, is very defective. He says, indeed, that no accurate account of it has ever been published [illegible] his own, of which we shall now lay an [illegible] our readers.

"All kinds of horse or ass skin, which have been dressed in such a manner as to appear grained are, by the Tartars, called *saumer*, by the Persians *sogre*, and by the Turks *sagri*, from which the Europ[illegible] made *shagreen* or *chagrin*. The Tartars who reside at Astracan, with a few of the Armenians of that city, are the only people in the Russian empire acquainted [illegible] the art of making shagreen. Those who follow this occupation not only gain considerable profit by the sale of their production to the Tartars of Cuban, Astracan, and Casan, who ornament with it their Turkey leather boots, slippers, and other articles made of leather, but they derive considerable advantage from the great sale of horses hides, which have undergone no other process than that of being scraped clean, and of which several thousands are annually exported, at the rate of from 75 to 85 roubles per hundred, to Persia, where there is a scarcity of such hides, and from which the greater part of the shagreen manufactured in that country is prepared. The hind part only of the hide, however, which is cut out in the form of a crescent about a Russian ell and a half in length across the loins, and a short ell in breadth along the back, can properly be employed for shagreen. The remaining part, as is proved by experience, is improper for that purpose, and is therefore rejected.

"The preparation of the skins, after being cut into the above form, is as follows:—They are deposited in a tub filled with pure water, and suffered to remain there for several days, till they are thoroughly soaked, and the hair has dropped off. They are then taken from the tub, one by one, extended on boards, placed in an oblique direction against a wall, the corners of them, which reach beyond the edges of the board, being made fast, and the hair with the epidermis is then scraped off with a blunt iron scraper called *urak*. The skins thus cleaned are again put in pure water to soak. When all the skins have undergone this part of the process, they are taken from the water a second time, spread out one after the other as before, and the fleshy side is scraped with the same kind of instrument. They are carefully cleaned also on the hair side, so that nothing remains but the pure fibrous tissue, which serves for making parchment, consisting of coats of white [illegible]dullary fibres, and which has a resemblance to a swine's bladder softened in water.

"After this preparation, the workmen take a certain kind of frames called *pilon*, made of a straight and a semicircular piece of wood, having nearly the same form as the skins. On these the skins are extended in as smooth and even a manner as possible by means of cords; and during the operation of extending them, they are several times besprinkled with water, that no part of them may be dry, and occasion an unequal tension. After they have been all extended on the frames, they are again moistened, and carried into the house, where the frames are deposited close to each other on the floor with the flesh side of the skin next the ground. The upper side is then thickly bestrewed with the black exceedingly smooth and hard seeds of a kind of goose foot (*chenopodium album*), which the Tartars call *alabuta*, and which grows in abundance, to about the height of a man, near the gardens and farms on the south side of the Volga; and that they may mak[e a] strong impression on the skins, a piece of felt is spread over them, and the seeds are trod down with the feet, by which means they are deeply imprinted into the soft skins. The frames, without shaking the seeds, are then carried out into the open air, and placed in a reclining position against a wall to dry, the side covered with the seeds being next the wall, in order that it may be sheltered from the sun. In this state the skins must be left several days to dry in the sun, until no appearance of moisture is observed in them, when they are fit to be taken from the frames. When the impressed seeds are beat off from the hair side, it appears full of indentations or inequalities, and has acquired that impression which is to produce the grain of the shagreen, after the skins have been subjected to the last smoothing or scraping, and have been dipped in a ley, which will be mentioned hereafter, before they receive the dye.

"The operation of smoothing is performed on an inclined bench or board, which is furnished with an iron hook, and is covered with thick felt of sheep's wool, on

Shagreen. on which the dry skin may gently rest. The skin is suspended in the middle of the bench or board to its iron hook, by means of one of the holes made in the edge of the skin for extending it in its frame as before mentioned; and a cord, having at its extremity a stone or a weight, is attached to each end of the skin, to keep it in its position while under the hands of the workman. It is then subjected to the operation of smoothing and scraping by means of two different instruments. The first used for this purpose, called by the Tartars *tokar*, is a piece of sharp iron bent like a hook, with which the surface of the shagreen is pretty closely scraped to remove all the projecting inequalities. This operation, on account of the corneous hardness of the dry skin, is attended with some difficulty; and great caution is at the same time required that too much of the impression of the *alabuta* seed be not destroyed, which might be the case if the iron were kept too sharp. As the iron, however, is pretty blunt, which occasions inequalities on the shagreen, this inconvenience must afterwards be remedied by means of a sharp scraping iron or *urak*, by which the surface acquires a perfect uniformity, and only faint impressions of the *alabuta* seed then remain, and such as the workman wishes. After all these operations, the shagreen is again put into water, partly to make it pliable, and partly to raise the grain. As the seeds occasion indentations in the surface of the skin, the intermediate spaces, by the operations of smoothing and scraping, lose some part of their projecting substance; but the points which have been depressed, and which have lost none of their substance, now swell up above the scraped parts, and thus form the grain of the shagreen. To produce this effect, the skins are left to soak in water for 24 hours; after which they are immersed several times in a strong warm ley, obtained, by boiling, from a strong alkaline earth named *schora*, which is found in great abundance in the neighbourhood of Astracan. When the skins have been taken from this ley, they are piled up, while warm, on each other, and suffered to remain in that state several hours; by which means they swell, and become soft. They are then left 24 hours in a moderately strong pickle of common salt, which renders them exceedingly white and beautiful, and fit for receiving any colour. The colour most usual for these skins is a sea-green; but old experienced workmen can dye them blue, red, or black, and even make white shagreen

"For the green colour nothing is necessary but filings of copper and sal ammoniac. Sal ammoniac is dissolved in water till the water is completely saturated; and the shagreen skins, still moist, after being taken from the pickle, are washed over with this solution on the ungrained flesh side, and when well moistened a thick layer of copper filings is strewed over them: the skins are then folded double, so that the side covered with the filings is innermost. Each skin is then rolled up in a piece of felt; the rolls are all ranged together in proper order, and they are pressed down in an uniform manner by some heavy bodies placed over them, under which they remain 24 hours. During that period, the solution of sal ammoniac dissolves a quantity of the cupreous particles sufficient to penetrate the skin and to give it a sea-green colour. If the first application be not sufficient, the process is repeated in the same manner; after which the skins are spread out and dried.

"For the blue dye, indigo is used. About two pounds of it, reduced to a fine powder, are put into a kettle; cold water is poured over it, and the mixture is stirred round till the colour begins to be dissolved. Five pounds of pounded *alakar*, which is a kind of barilla or crude soda, prepared by the Armenians and Calmucs is then dissolved in it, with two pounds of lime and a pound of pure honey, and the whole is kept several days in the sun, and during that time frequently stirred round. The skins intended to be dyed blue must be moistened only in the natrous ley *schora*, but not in the salt brine. When still moist, they are folded up and sewed together at the edge, the flesh side being innermost, and the shagreened hair side outwards; after which they are dipped three times in the remains of an exhausted kettle of the same dye, the superfluous dye being each time expressed; and after this process they are dipped in the fresh dye prepared as above, which must not be expressed. The skins are then hung up in the shade to dry; after which they are cleaned and paired at the edges.

"For black shagreen, gall-nuts and vitriol are employed in the following manner:—The skins, moist from the pickle, are thickly bestrewed with finely pulverised gall nuts. They are then folded together, and laid over each other for 24 hours. A new ley, of bitter saline earth or *schora*, is [the ...]red, and poured hot into [...] In [...]y each skin is several times [...]e again bestrewed with [...] for a certain [...] penetrate them, and the [...] from the dust of [...] are rubbed [...] tallow, [...] imbibe [...] med also [...] squeeze it w[...] in order to [...] superfluous particles are [...] wooden scraper (*urgc*); and [...]ed, and the skins have lain some time, [...]tity of vitriol of iron is dissolved [...] which the shagreen is moistened on [...] operation it [...] It is then dressed at the [...] where there are any blemis[hes.]

"To obtain white shagreen, the skins must first be moistened on the shagreen side with a strong solution of alum. When the skin has imbibed this liquor, it is daubed over on both sides with a paste made of flour, which is suffered to dry. The paste is then washed off with alum-water, and the skin is placed in the sun till it is completely dry. As soon as it is dry, it is gently besmeared with pure melted sheep's tallow, which it is suffered to imbibe in the sun; and to promote the effect, it is pressed and worked with the hands. The skins are then fastened in succession to the before-mentioned bench, where warm water is poured over them, and the superfluous fat is scraped off with a blunt wooden instrument. In the last operation the warm water is of great service. In this manner shagreen perfectly white is obtained, and nothing remains but to pare the edges and dress it.

"But this white shagreen is not intended so much for

Shagreen. Sharp.

for remaining in that state, as for receiving a dark red dye; because, by the above previous process, the colour becomes much more perfect. "The skins destined for a red colour must not be immersed first in ley of bitter salt earth (*schora*), and then in pickle, but after they have been whitened, must be left to soak in the pickle for 24 hours. The dye is prepared from cochineal, which the Tartars call *kirmitz*. About a pound of the dried herb *tschagann*, which grows in great abundance in the neighbourhood of Astracan, and is a kind of soda plant or kali (*salsola ericoides* (A)), is boiled a full hour in a kettle containing about four common pailfuls of water; by which means the water acquires a greenish colour. The herb is then taken out, and about half a pound of pounded cochineal is put into the kettle, and the liquor is left to boil a full hour, care being taken to stir it that it may not run over. About 15 or 20 drams of a substance which the dyers call *lüter* (orchilla) is added, and when the liquor has been boiled for some time longer, the kettle is removed from the fire. The skins taken from the pickle are then placed over each other in troughs, and the dye liquor is poured over them four different times, [illegible]bed into them with the hands, th[illegible]ually imbibed and diffused. The [illegible]pressed; after which they are fit [illegible] dried. [illegible] prepared in this manner are [illegible] than any of the other kinds."

SHARP (Abraham), an eminent mathematician, mechanist, and astronomer, was descended from an ancient family at Little Horton, near Bradford, in the West Riding of Yorkshire, where he was born about the year [illegible]. [illegible] he was put apprentice to a mer[illegible]; but his genius led him to [illegible] both theoretical and practical [illegible] in that situation of life. By the [illegible] therefore, of his master and [illegible] with that of his father, he quitted the business of a merchant. Upon this he removed to Liverpool, where he gave himself up wholly to the study of mathematics, astronomy, &c.; and where, for a subsistence, he opened a school, and taught writing and accounts, &c.

He had not been long at Liverpool when he accidentally fell in company with a merchant or tradesman visiting that town from London, in whose house it seems the astronomer Mr Flamsteed then lodged. With the view therefore of becoming acquainted with this eminent man, Mr Sharp engaged himself with the merchant as a book-keeper. In consequence he soon contracted an intimate acquaintance and friendship with Mr Flamsteed, by whose interest and recommendation he obtained a more profitable employment in the dock-yard at Chatham; where he continued till his friend and patron, knowing his great merit in astronomy and mechanics, called him to his assistance, in contriving, adapting, and fitting up the astronomical apparatus in the Royal Observatory at Greenwich, which had been built, namely, about the year 1676. He was principally employed in the construction of the mural arch; which in the compass of 14 months he finished so greatly to the satisfaction of Mr Flamsteed, that he speaks of him in terms of the highest praise. According to Mr Smeaton, this was the first good and valid instrument of the kind; and Mr Sharp the first artist who cut accurate and delicate divisions upon astronomical instruments. At the time this instrument was constructed, Mr Flamsteed was 30 and Mr Sharp 25 years of age.

Sharp.

These two friends continued together for some time, making observations on the meridional zenith distances of the fixed stars, sun, moon, and planets, with the times of their transits over the meridian; also the diameters of the sun and moon, and their eclipses, with those of Jupiter's satellites, the variation of the compass, &c.

Mr Sharp assisted Mr Flamsteed also in making a catalogue of near 3000 fixed stars, with their longitudes and magnitudes, their right ascensions and polar distances, with the variations of the same while they change their longitude by one degree.

But from the fatigue of continually observing the stars at night, in a cold thin air, joined to a weakly constitution, he was reduced to a bad state of health; for the recovery of which he desired leave to retire to his house at Horton; where, as soon as he found himself on the recovery, he began to fit up an observatory of his own; having first made an elegant and curious engine for turning all kinds of work in wood or brass, with a maundril for turning irregular figures, as ovals, roses, wreathed pillars, &c. Beside these, he made himself most of the tools used by joiners, clockmakers, opticians, mathematical instrument makers, &c. The limbs or arcs of his large equatorial instrument, sextant, quadrant, &c. he graduated with the nicest accuracy, by diagonal divisions into degrees and minutes. The telescopes he made use of were all of his own making, and the lenses ground, figured, and adjusted with his own hands.

It was at this time that he assisted Mr Flamsteed in calculating most of the tables in the second volume of his *Historia Cœlestis*, as appears by their letters, to be seen in the hands of Mr Sharp's friends at Horton. Likewise the curious drawings of the charts of all the constellations visible in our hemisphere, with the still more excellent drawings of the planispheres both of the northern and southern constellations. And though these drawings of the constellations were sent to be engraved at Amsterdam by a masterly hand, yet the originals far exceeded the engravings in point of beauty and elegance: these were published by Mr Flamsteed, and both copies may be seen at Horton.

The mathematician, says Dr Hutton, meets with something extraordinary in Sharp's elaborate treatise of *Geometry Improved* (in 4to, 1717, signed A. S. Philomath): 1st, by a large and accurate table of segments of circles, its construction and various uses in the solution of several difficult problems, with compendious tables for

(A) The beautiful red Turkey leather is dyed with cochineal prepared in the same manner. Professor Gmelin junior, in the second part of his Travels through Russia, explains the herb *tschagann* by *artemisia annua*, having doubtless been deceived by the appearance the plant acquires after it has been dried. Besides, this *artemisia* is found only in the middle of Siberia, and never on the west side of the Irtisch.

for finding a true proportional part; and their use in these or any other tables exemplified in making logarithms, or their natural numbers, to 60 places of figures; there being a table of them for all primes to 1100, true to 61 figures. 2d. His concise treatise of Polyedra, or solid bodies of many bases, both the regular ones and others: to which are added twelve new ones, with various methods of forming them, and their exact dimensions in surds, or species, and in numbers; illustrated with a variety of copperplates, neatly engraved by his own hands. Also the models of these polyedra he cut out in boxwood with amazing neatness and accuracy. Indeed few or none of the mathematical instrument makers could exceed him in exactly graduating or neatly engraving any mathematical or astronomical instrument, as may be seen in the equatorial instrument above mentioned, or in his sextant, quadrants, and dials of various sorts; also in a curious armillary sphere, which, beside the common properties, has moveable circles, &c. for exhibiting and resolving all spherical triangles; also his double sector, with many other instruments, all contrived, graduated, and finished, in a most elegant manner, by himself. In short, he possessed at once a remarkably clear head for contriving, and an extraordinary hand for executing, any thing, not only in mechanics, but likewise in drawing, writing, and making the most exact and beautiful schemes or figures in all his calculations and geometrical constructions.

The quadrature of the circle was undertaken by him for his own private amusement in the year 1699, deduced from two different series, by which the truth of it was proved to 72 places of figures; as may be seen in the introduction to Sherwin's Tables of Logarithms; that is, if the diameter of a circle be 1, the circumference will be found equal to 3·14159265358979323846264338327950288419716939937510582097494459230781640 5, &c. In the same book of Sherwin's may also be seen his ingenious improvements on the making of logarithms, and the constructing of the natural sines, tangents, and secants.

He also calculated the natural and logarithmic sines, tangents, and secants, to every second in the first minute of the quadrant; the laborious investigation of which may probably be seen in the archives of the Royal Society, as they were presented to Mr Patrick Murdoch for that purpose; exhibiting his very neat and accurate manner of writing and arranging his figures, not to be equalled perhaps by the best penman now living.

Mr Sharp kept up a correspondence by letters with most of the eminent mathematicians and astronomers of his time, as Mr Flamsteed, Sir Isaac Newton, Dr Halley, Dr Wallis, Mr Hodgson, Mr Sherwin, &c. the answers to which letters are all written upon the backs, or empty spaces, of the letters he received, in a short-hand of his own contrivance. From a great variety of letters (of which a large chestful remain with his friends) from these and many other celebrated mathematicians, it is evident that Mr Sharp spared neither pains nor time to promote real science. Indeed, being one of the most accurate and indefatigable computers that ever existed, he was for many years the common resource for Mr Flamsteed, Sir Jonas Moore, Dr Halley, and others, in all sorts of troublesome and delicate calculations.

Mr Sharp continued all his life a bachelor, and spent his time as recluse as a hermit. He was of a middle stature, but very thin, being of a weakly constitution. He was remarkably feeble the last three or four years before he died, which was on the 18th of July 1742, in the 91st year of his age.

In his retirement at Little Horton, he employed four or five rooms or apartments in his house for different purposes, into which none of his family could possibly enter at any time without his permission. He was seldom visited by any persons, except two gentlemen of Bradford, the one a mathematician, and the other an ingenious apothecary; these were admitted, when he chose to be seen by them, by the signal of rubbing a stone against a certain part of the outside wall of the house. He duly attended the dissenting chapel at Bradford, of which he was a member, every Sunday; at which time he took care to be provided with plenty of halfpence, which he very charitably suffered to be taken singly out of his hand, held behind him during his walk to the chapel, by a number of poor people who followed him, without his ever looking back, or asking a single question.

Mr Sharp was very irregular as to his meals, and remarkably sparing in his diet, which he frequently took in the following manner. A little square hole, something like a window, made a communication between the room where he was usually employed in calculations, and another chamber or room in the house where a servant could enter; and before this hole he had contrived a sliding board: the servant [illegible] placed his victuals in this hole, without speaking [illegible] any the least noise; and when he [illegible] he visited his cupboard to see what [illegible] his hunger or thirst. But [illegible] e breakfast, dinner, and supper [illegible] untouched by him, when the servant has gone to remove what was left—so deeply engaged had he been in calculations.

SHARPS in fount, the finer part of what we have denominated POLLARDS. See that article, *Suppl.*

SHASTAH, the same as SHASTER; which see, *Encycl.*

SHEA, the name of a tree, from the fruit of which the Negroes, in the interior [illegible] of Africa between the tropics, prepare a kind of [illegible]. These trees are not planted by the [illegible] are found growing naturally in the woods [illegible] ring wood land for cultivation, every tree [illegible] wn but the Shea. The tree itself very much [illegible] the American oak; and the fruit, from the kernel of which being first dried in the sun the butter is prepared, by boiling the kernel in water, has somewhat the appearance of a Spanish olive. The kernel is enveloped in a sweet pulp, under a thin green rind; and the butter produced from it, besides the advantage of its keeping the whole year without salt, is whiter, firmer, and, Mr Park says, to his palate, of a richer flavour than [illegible] best butter which he ever tasted made from cows [illegible] The growth and preparation of this commodity [illegible] to be among the first objects of African indu[illegible] this and the neighbouring states; and it constitutes [illegible] main article of their inland commerce. In some places they dry the fruit in kilns, containing each about half a cart load of fruit, under which is kept up a clear wood fire. Our author, who saw the fruit in one of these kilns, was informed, that in three days the fruit would

Sheave, Shebbeare.

would be ready for pounding and boiling; and that the butter thus manufactured, is preferable to that which is prepared from fruit dried in the sun; especially in the rainy season, when the process by insolation is always tedious, and oftentimes ineffectual. Might it not be worth while, if practicable, to cultivate Shea-trees in some of our West India islands?

SHEAVE, in mechanics, a solid cylindrical wheel, fixed in a channel, and moveable about an axis, as being used to raise or increase the mechanical powers applied to remove any body.

SHEBBEARE (John) was born at Bideford, a considerable sea-port and corporation town in Devonshire, in the year 1709. His father was an attorney; but having small practice and little fortune, he carried on also the business of a corn-factor. He had four children, two sons and two daughters. Of the sons, John, the subject of our present memoir, was the eldest. The other son was called Richard, and entirely the reverse of his brother in disposition; he was bred to the sea, and died young.

John received the rudiments of his education at the free grammar school of Exeter, then conducted by the learned Mr Zachary Mudge (author of an Essay for a new Version of the Psalms, and a volume of excellent Sermons), afterwards Rector of St Andrew in Plymouth. It has oftentimes been remarked, that the future life of a man may be nearly guessed at from his puerile character. Thus Shebbeare, while a schoolboy, gave the strongest indications of his future emi- [illegible] arkable [illegible] ness of his [illegible] of his disposition; being universal [illegible] d of satirising genius, while at [illegible] generally [illegible] for his malicious and [illegible]. This may easily be believed, when [illegible] formed not one connection, either a[illegible] any person in the way of [illegible] with a young barber of an [illegible], whose soul was perfectly congenial to that of Shebbeare's.

Such is the account of Shebbeare's boyish years which we have in the 14th volume of the *European Magazine*. It is probably much exaggerated; for Shebbeare continued through life a staunch Tory, if not a Jacobite; and it is well known that many of our journalists consider themselves as at liberty to give what characters they please of such men.

In the fifteenth or sixteenth year of his age, young Shebbeare was bound apprentice to a very eminent and worthy surgeon in his native town; in which situation he acquired a considerable share of medical knowledge. His genius for lampoon appeared at this early period, and he could not forbear from exercising it on his master. No one indeed could give him the slightest offence with impunity; for which reason almost every [illegible]n avoided his acquaintance, as we would avoid the sting of an adder. The chief marks, however, of the [illegible] of his wit were the gentlemen of the corpora[illegible] one or other, and sometimes all of them, were almost constantly exposed in a libel upon the public posts and corners of the streets. But though the wiser part of them only laughed at these harmless trifles, yet some were more irritable, and many a prosecution was commenced against, but not one could fix itself upon him, so artfully had h[e] contrived to conceal himself. He was also several times summoned to appear at the sessions, for daring to speak and write irreverently of the worshipful magistrates; but the laugh was always on the side of Shebbeare, nor could they ever come at his back, so closely had he fitted on his armour, with the whip of authority.

When he was out of his time he set up trade for himself, and then shewed a taste for chemistry; and soon after he married a very agreeable and amiable young woman, of no fortune, but of a genteel family. Whether his insuperable propensity to satire deprived him of friends and of business, or that he spent too much in chemical experiments, we know not; but failing at Bideford, he removed, about the year 1736, to Bristol, where he entered into partnership with a chemist, and never afterwards set his foot in his native town.

In the year 1739 he attracted the attention of the public, by an epitaph to the memory of Thomas Coster, Esq; member for Bristol; in which, it has been truly observed, that he has contrived to raise emotions of pity, grief, and indignation, to a very high degree. The next year he published a pamphlet on the Bristol waters; from which period there is a chasm in our author's life we are unable to fill up. In this interval may probably be placed his failure in business, and his effort to obtain a higher situation in his profession. It is certain that in the year 1752 he was at Paris, and there he obtained the degree, if he obtained it at all, which gave him the addition to his name which accompanied him during the rest of his life, that of Doctor. Until this time he appears to have lived in obscurity; but at an age when vigorous exertion usually subsides, he seems to have resolved to place himself in a conspicuous situation, whatever hazard might attend it, and commenced a public writer with a degree of celerity and virulence for which it would be difficult to find a parallel even in the most intemperate times. To read over his works now, when the passions they then raised have subsided, we feel surprise at the effect they produced; and it is within the memory of many yet living, that their influence was very considerable. In the year 1754 he began his career with The Marriage Act, a political novel; in which he treated the legislature with such freedom, that it occasioned his being taken into custody, from whence, however, he was soon released.

The performances, however, most celebrated, were a series of Letters to the People of England, which were written in a style vigorous and energetic, though slovenly and careless, well calculated to make an impression on common readers; and were accordingly read with avidity, and circulated with diligence. They had a very considerable effect on the minds of the people, and galled the ministry, who seem to have been at first too eager to punish the author. On the publication of the Third Letter, we find warrants, dated 5th and 8th of March, 1756, issued by Lord Holdernesse, to take up both Scott the publisher and the author. This prosecution, however, seems to have been dropt, and the culprit proceeded for some time unmolested, "having declared (says one of his answerers) that he would write himself into a post or into the pillory; in the last of which he at length succeeded." On the 12th of January 1758, a general warrant was signed by Lord Holdernesse, to search for the author,

printer,

printer, and publishers of a wicked, audacious, and treasonable libel, entitled, "A Sixth Letter to the People of England, on the progress of national ruin; in which is shewn that the present grandeur of France and calamities of this nation are owing to the influence of Hanover on the councils of England;" and them having found, to seize and apprehend, together with their books and papers.

At this juncture government seem to have been effectually roused; for having received information that a seventh letter was printing, by virtue of another warrant, dated January 23, all the copies were seized and entirely suppressed. In Easter Term an information was filed against him by Mr Pratt, then attorney general, afterwards Lord Camden; in which it is now worthy of remark, that the crown officer, in his application to the court, in express terms admitted a point, since much disputed, that of the jury's right to determine both the law and the fact in matters of libel. "What I urge (says the advocate) to the court, is only to shew there is reasonable ground for considering this publication as a libel, and for putting it in a way of trial, and therefore it is I pray to have the rule made absolute; for I admit, and your lordship well knows, that the jury in matter of libel are judges of the law as well as the fact, and have an undoubted right to consider whether, upon the whole, the pamphlet in question be, or be not, a false, malicious, and scandalous libel." On the 17th of June, the information was tried, when our author was found guilty; and on the 28th November, he received sentence, by which he was fined five pounds, ordered to stand in the pillory December 5, at Charing Cross, to be confined three years, and to give security for his good behaviour for seven years, himself in 500l. and two others in 250l. each.

On the day appointed, that part of the sentence which doomed him to the pillory was put in execution, amidst a prodigious concourse of people assembled on the occasion. The under sheriff, at that time, happened to be Mr Beardmore, who had sometimes been assisted by the Doctor in writing the Monitor, a paper in its principles of the same tendency with the writings of the culprit, who consequently might expect every indulgence from the officer to whom the execution of his sentence was committed. The manner in which it was conducted may be learned from the affidavits on which afterwards the under sheriff's conduct became the subject of animadversion in the court of King's Bench, and which assert, "that the defendant only stood upon the platform of the pillory, unconfined, and at his ease, attended by a servant in livery (which servant and livery were hired for the occasion only) holding an umbrella over head all the time: but his head, hands, neck, and arms, were not at all confined, or put into the holes of the pillory; only that he sometimes put his hands upon the holes of the pillory in order to rest himself." For this neglect of duty, Beardmore was fined 50l. and suffered two months imprisonment.

Some time before he was tried for the obnoxious publication already mentioned, the Duchess of Queensbury, as heir of Lord Clarendon, obtained an injunction in the Court of Chancery to stop the publication of the continuation of that nobleman's history; a copy of which had got into the hands of Francis Gwyn, Esq; between whom and the Doctor there had been an agreement to publish it and equally divide the profits. The care and expences attending the ushering this work into the world were to be wholly Dr Shebbeare's, who performed his part of the agreement, and caused it to be handsomely printed in quarto, with a Tory preface, containing frequent reflections on, and allusions to recent events, and to living characters, which gave it the appearance rather of a temporary pamphlet than of a work calculated for posterity. On the injunction being obtained, Dr Shebbeare was under the necessity of applying to the aid of law to recover the money expended by him in printing, amounting to more than 500l. Of that sum more than half had been wasted on his side in the courts of law and equity. And some years afterwards, speaking of the situation of his affairs, he says, "It may be easily imagined, that my circumstances were not improved by three years imprisonment. I had no club of partizans to maintain me during that time, to discharge my debts, nor even the fine, which I was obliged to pay after a three years confinement for a single offence. Notwithstanding the difficulties which inevitably arose from these particulars, and although an insolvent act was passed soon after his Majesty's accession to the throne, and my circumstances might have apologised for my taking that opportunity which is offered; I nevertheless declined from availing myself of that occasion to evade the payment of my debts. I preferred the labour of endeavouring to pay them, and the risk of being again imprisoned if I did not succeed. But, thank Heaven, I am in no [illegible] ment on that account." [illegible] he declares he never received [illegible] than twenty guineas from all the world.

While he was confined in the King's Bench, he solicited subscriptions for the first volume of a History of England, from the Revolution to the then present time. But at the persuasion of his friends he was induced to alter his design, and receipts were issued for a first volume of the History of England, and of the Constitution thereof, from its origin. That volume he wrote, and had transcribed. "But as it was impracticable (to use his own words), whilst I was in confinement, to procure that variety of books, as to apply to manuscript authorities, for all that was requisite to the completing of this first volume, I found, on being released from my imprisonment, and on application to the former only, that the volume which I had written was incorrect, insufficient, and erroneous, in too many particulars, to admit of its being published, without injustice to my subscribers, and reprehensions on myself. Into this displeasing situation I had been misled by relying on the authorities of modern historians, who pretend to cite the authors from whence their materials are taken, many of whom appear never to have seen them, but implicitly to have copied one another, and all of them manifestly defective; not only in the authorities they should have sought, but in their omissions and misrepresentations of those whom they had consulted: more especially respecting those parts of the old German codes, on which our constitution is erected, and without which it cannot be properly explained or understood. Such being the real situation of things, I perceived that more time than I could expect to live would be necessarily required for so extensive a work as the

Shebbeare.

Shebbeare

the whole history I had proposed; and that a single volume, or even a few volumes of an history incomplete would by no means answer either the intention of my subscribers, or my own: I determined therefore to change my plan, and to include in one volume that which might require no others to complete this new design.

"In consequence of this alteration, I resolved to exert my best abilities, not only to trace the constitution of England from its origin in the woods of Germany, as M. de Montesquieu expresses it, but from the first principles of human nature, from which the formation of all kinds of government is derived. With this view, I have attempted an analyzation of the mental and corporeal faculties, in order to shew in what manner they reciprocally influence each other in the various actions of man, not only as an individual, but as a gregarious being, impelled by nature to associate in communities. From hence I have attempted to delineate in what manner legislature sprang and proceeded from its source, through that variety of meanders which it hath formed in its current, both before and since the introduction of one common sign, whereby to express the intrinsic value, not only of all the productions of nature and of art, but even of the human faculties, as they are now estimated; to compare the constitutions of those different states which have been, and are the most celebrated in ancient and modern history, with each other, and with that of England; and then to derive some reasonable grounds for the determination of that which seems to be the most consentaneous with the primogenial instincts of nature, and the happiness of human kind. In consequence of this intent, the manners that successively arose and prevailed in such states, the benefits and mischiefs which ensued from them, are delineated, in order to explain on what foundation the welfare of national communities may most probably be established."

This plan, thus delineated, he at times employed himself in filling up; but on being rudely attacked for not performing his promise with his subscribers, he, in 1774, observed—"From the inevitable obligations, not only of supporting my own family, but those also whom as son and brother it was my duty to fulfill for forty years, and which, respecting the claims of the latter, still continues; it will be easily discerned that many an avocation must have proceeded from these circumstances, as well as from a sense of gratitude to his majesty, in defence of whose government I have thought it my duty occasionally to exert my best abilities." He adds, however, that he did not intend to die until what he had proposed was finished; a promise which the event has shewn he was unable to perform.

In prison he was detained during the whole time of the sentence, and with some degree of rigour; for when his life was in danger from an ill state of health, and applied to the court of King's Bench for permission carried into the rules a few hours in a day, tho' Mansfield acceded to the petition, yet the prayer of it was denied and defeated by Judge Foster. At the expiration of the time of his sentence, a new reign had commenced; and shortly afterwards, during the administration of Mr Grenville, a pension was granted him by the crown. This he obtained by the personal application of Sir John Philips to the King, who, on that occasion, was pleased to speak of him in very favourable terms, which he promised undeviatingly to endeavour to deserve by allegiance and gratitude.

Shebbeare.

From the time of that event we find Dr Shebbeare a uniform defender of the measures of Government, and the mark against whom every opposer of administration considered himself at liberty to throw out the grossest abuse. Even the friends of power were often adverse to him. Dr Smollet introduced him in no very respectful light, under the name of Ferret, in the novel of Sir Launcelot Greaves, and Mr Hogarth made him one of the group in the third election print.

Scarce a periodical publication was without some abuse of him, which he seems to have in general had the good sense to neglect. In the year 1774, however, he departed from his general practice, and defended himself from some attacks at that time made upon him. In this pamphlet he represented the conduct and character of King William in such a light as to excite the indignation of every Whig in the kingdom: he treated him in print with as great severity as Johnson used to do in conversation.

Early in life he appears to have written a comedy, which in 1766 he made an effort to get represented at Covent Garden. In 1768 he wrote the Review of Books in the Political Register for three months, and was often engaged to write for particular persons, with whom he frequently quarrelled when he came to be paid. This was the case with Sir Robert Fletcher, and we think of others. His pen seems to have been constantly employed, and he wrote with great rapidity, what certainly can now be read with little satisfaction, and must soon be forgotten. Though pensioned by government, he can scarce be said to have renounced his opinions; for in the pamphlet already mentioned, his abuse of the Revolution is as gross as in that for which he suffered the pillory. His violence defeated his own purpose, and made those who agreed in party with him revolt from the virulence with which he treated his adversaries. During the latter years of his life he seems to have written but little. He was a strenuous supporter of the ministry during the American war, having published, in 1775, An Answer to the printed Speech of Edmund Burke, Esq; spoken in the House of Commons, April 19, 1774. In which his knowledge in polity, legislature, human kind, history, commerce, and finance, is candidly examined; his arguments are fairly refuted; the conduct of administration is fully defended; and his oratoric talents are clearly exposed to view.—And An Essay on the Origin, Progress, and Establishment of National Society; in which the principles of Government, the definitions of physical, moral, civil, and religious Liberty contained in Dr Price's Observations, &c. are fairly examined, and fully refuted; together with a justification of the Legislature in reducing America to obedience by force. To which is added, an Appendix on the Excellent and Admirable in Mr Burke's second printed Speech of the 22d of March 1775, both 8vo.

His publications, satirical, political, and medical, amount to thirty-four, besides a novel, entitled Lydia, or Filial Piety; in which religious hypocrisy and blustering courage are very properly chastised. He died on the 1st of August 1788, leaving, among those who knew him best, the character of a benevolent man; a

character which, from the manner in which he speaks of his connections, he probably deserved.

SHEERS, aboard a ship, an engine used to hoist or displace the lower masts of a ship.

SHEIBON, a district in Africa, lying to the south-east of the kingdom of Dar-Fur (See SOUDAN in this volume), where much gold is found both in dust and in small pieces. The natives, who are idolaters and savages, collect the dust in quills of the ostrich and vulture, and in that condition sell it to the merchants. They have a ceremony on discovering a large piece of gold, of killing a sheep on it before they remove it. The people, who are all black, have some form of marriage, *i. e.* of an agreement between man and woman to cohabit. Women of full age wear a piece of platted grass on their parts. The younger and unmarried are quite naked. The slaves, which are brought in great numbers from this quarter, are some prisoners of war among themselves (for their wars are frequent), and some seduced by treachery, and sold. But it is said to be a common practice for a father in time of scarcity to sell his children.

At Sheibon are some Mohammedans, who live among the idolaters, and wear clothing: it is not said whether Arabs or not. Mr Browne, from whose travels we have taken this account of Sheibon, does not give its latitude or longitude.

SHILLUK, a town in Africa on the banks of the Bahr-el-abiad, or true Nile. The houses are built of clay, and the inhabitants, who are idolaters, have no other clothing than bands of long grass, which they pass round the waist and between the thighs. They are all black; both sexes are accustomed to shave their heads. The people of Shilluk have the dominion of the river, and take toll of all passengers, in such articles of traffic as pass among them. The name Shilluk is not Arabic, and its meaning is unknown.—When asked concerning their name or country, the people reply Shilluk. When employed in transporting Mohammedans across the ferry, they occasionally exhibit the importance which their situation gives them. After the Muslim has placed himself in the boat, they will ask him, "Who is the master of that river?" The other replies, as is usual, "Ullah or Rubbani"—God is the master of it. "No (answers the Shilluk), you must say that such a one (naming his chief) is the master of it, or you shall not pass." They are represented as shewing hospitality to such as come among them in a peaceable manner, and as never betraying those to whom they have once accorded protection. The particulars of their worship have not been described. In Mr Browne's map, Shilluck is placed in about 13° N. Lat. and 32° 26′ E. Long.

SHIP. See that article, and SHIPBUILDING (*Encycl.*), and likewise *FLOATING Bodies* (*Suppl.*) In the *Transactions of the Royal Society of London* for 1798, Mr Atwood has completed his disquisition on the *Stability* of Ships; but as the memoir cannot be abridged, we must refer the scientific naval architect to the original for much useful information.

A small work has lately been published by Charles Gore, Esq; of Weimar in Saxony, upon *the respective Velocity of Floating Bodies varying in Form.* It contains merely the results of two series of experiments: from the first of which series, it seems to appear that the form best calculated for velocity is a long parallel body, terminating at each end in a parabolic cuneus, and having the extreme breadth in the centre. Also, that making the cuneus more obtuse than is necessary to break with fairness the curve line into the straight, creates a considerable degree of impediment. And Mr Gore is inclined to think, that the length of ships, which has already been extended with success, to four times the breadth, is capable, with advantage, of still further extension, perhaps to five, and, in some cases, even to six times.

The second set of experiments was instituted to ascertain the respective degrees of stability, or power of resisting the pressure of the wind, in carrying sail, on bodies of different forms. The bodies used in the experiments had their specific capacities and weights precisely equal, but their forms different; and from the results, it appears that the form of a midship body, best adapted for stability only, is a flat bottom, with perpendicular sides; and that the next best adapted is a semicircle. But as there exists much difficulty in constructing the former with sufficient strength, besides its being ill adapted to heavy seas, as, by the sudden descent in pitching, the bottom will strike the water nearly at right angles, and sustain thereby a tremendous shock. And as the latter seems to be too inclinable to transverse oscillation, or rolling, and also to be deficient in capacity for many services, our author is of opinion, that a midship body, of a compounded form, is most applicable to general purposes.

On account [illegible] ue we are unable to speak critically [illegible] tract. To benefit naval architectu[illegible] on, that the method of experiment i[illegible] is than that of calculation [illegible] riments must be drawn with great caution. It is by no means certain that a result obtained for a body of a given bulk will obtain for similar bodies which differ in dimensions.

We shall conclude this short article with a statement of the principles upon which Patrick Miller, Esq; of Dalswinton (Scotland), proposes to construct ships and vessels which cannot founder.

The vessel is to be kept afloat, without the aid [illegible] sides, solely by the buoyancy of its bottom, which is flat; the bottom never being so deeply immersed as to bring the upper surface thereof on a level with the water; such vessels are being constructed for the purpose of carrying cargoes, but [illegible] with the necessary [illegible] vessels are not kept afloat by the aid of their sides, but by the buoyancy of their bottom, as above described, they cannot sink, and therefore pumps are not required, nor are they in any respect necessary for the preservation of such vessels. The said vessel is put in motion, during calms, and against light winds, by means of wheels. These wheels project beyond the sides of the vessel, and are wrought by means of capstans: the number and the dimensions of the wheels depend upon the length of the vessel. These wheels are built with eight arms, which consist entirely of plank. Sliders are used to work and to keep the vessel to windward when under sail. These sliders are placed in the centre of the vessel, from stem to stern; they are made of plank, and the number and dimensions must depend on the length of the vessel; and they are raised and let down,

down, either by the hand, or by means of a purchase, according to the size of the vessel. Vessels of this construction draw water, in proportion to their dimensions, as follows: a vessel of forty feet in length, and from thirteen to nineteen feet in breadth, will draw from thirteen to sixteen inches of water. One of fifty feet in length, and from seventeen to twenty-four feet in breadth, will draw from fifteen to eighteen inches of water. One sixty feet long, and from twenty to twenty-eight feet broad, will draw from eighteen to twenty-one inches of water. One seventy feet long, and from twenty three to thirty-two feet broad, will draw from twenty-one to twenty-four inches of water. One eighty feet long, and from twenty-seven to thirty-seven feet broad, will draw from twenty-four to twenty-seven inches of water. One ninety feet long, and from thirty to forty-two feet broad, will draw from twenty-seven to thirty inches of water. One of one hundred feet in length, and from thirty-three to forty-seven feet in breadth, will draw from thirty to thirty three inches of water.

As, from the principle upon which this vessel is constructed, she cannot sink, the invention must prove a means of saving many lives; and as it will give more room and height between the decks than any vessel of the same dimensions of another construction, it must add greatly to the comfort and [illegible] ion of persons at sea of all descriptions. It is expected that, from these advantages, a more general and friendly intercourse amongst nations will take place, which will have the effect to diffuse knowledge, and to remove national prejudices, thereby promoting the general welf[illegible] of mankind. At [illegible] Mr Miller, it [illegible] be altogether [illegible] the [illegible] of ships of greater dimensions [illegible] would be [illegible] to a purpose very [illegible] by the inventor.

SHIPWRECK, a [illegible] disaster, by which numbers of lives are yearly lost. In that valuable miscellany entitled, *The Philosophical Magazine*, we have an account of means for preventing that loss, when the ship is in danger within two or three hundred fathoms of the shore; and as the anonymous author (a Frenchman) says that he has by experiment ascertained the efficacy of these means, we shall give them to our readers.

The only certain means of [illegible] the crew of a vessel in such a state is, to establish a rope of communication from the shore to the ship. But how is this to be done? The author says, by fixing the end of [illegible] bomb or cannon ball, and extending the rope afterwards, in a zig-zag direction, before the mortar or cannon, or suspending it on a piece of wood raised several feet. A rope, so placed, will not break (he says) by the greatest velocity which can be given to the bomb or ball; and thus the end of it can be sent ashore by a discharge of artillery. He prefers the bomb to the cannon ball, for reasons which he does not assign. He proposes, however, other means to effect his benevolent purpose.

"It ought to be remembered (says he), that a vessel is never cast away, or perishes on the coast, but because it is driven thither against the will of the captain, and by the violence of the waves and the wind, which almost always blows from the sea towards the shore, without which there would be no danger to be apprehended: consequently, in these circumstances, the wind comes always from the sea, either directly or obliquely, and blows towards the shore.

"*1st*, A common paper kite, therefore, launched from the vessel and driven by the wind to the shore, would be sufficient to save a crew consisting of 1500 seamen, if such were the number of a ship of war. This kite would convey to the shore a strong packthread, to the end of which might be affixed a cord, to be drawn on board by means of the string of the kite; and with this cord a rope, or as many as should be necessary, might be conveyed to the ship.

"*2d*, A small balloon, of six or seven feet in diameter, and raised by rarified air, would be also an excellent means for the like purpose: being driven by the wind from the vessel to the shore, it would carry thither a string capable of drawing a cord with which several ropes might be afterwards conveyed to the vessel. Had not the discovery of Montgolfier produced any other benefit, it would be entitled on this account to be considered as of great importance.

"*3d*, A sky-rocket, of a large diameter, would be of equal service. It would also carry, from the vessel to the shore, a string capable of drawing a rope after it.

"*Lastly*, A fourth plan for saving the [illegible] of a [illegible]wrecked vessel, is that of throwing from the vessel into the sea an empty cask with a cord attached to it. The wind and the waves would drive the cask to the shore, and afford the means of establishing that rope of [illegible]munication already mentioned."

SILLA, a large town on the Niger, which bounded Mr Park's travels eastward. He gives no description of the place, which he had not spirits or health to survey; but fills a page of his work with the reasons which determined him to proceed no farther. "When I arrived (says he), I was suffered to remain till it was quite dark, under a tree, surrounded by hundreds of people. But their language was very different from the other parts of Bambarra; and I was informed that, in my progress eastward, the Bambarra tongue was but little understood, and that when I reached Jenné, I should find that the majority of the inhabitants spoke a different language, called *Jenné Kummo* by the Negroes, and *Kalam Soudan* by the Moors.

"With a great deal of entreaty, the Dooty allowed me to come into his baloon, to avoid the rain; but the place was very damp, and I had a smart paroxysm of fever during the night. Worn down by sickness, exhausted with hunger and fatigue, half naked, and without any article of value, by which I might procure provisions, clothes, or lodging, I began to reflect seriously on my situation. I was now convinced, by painful experience, that the obstacles to my further progress were insurmountable. The tropical rains were already set in with all their violence; the rice grounds and swamps were everywhere overflowed; and in a few days more, travelling of every kind, unless by water, would be completely obstructed. The kowries which remained of the king of Bambarra's present were not sufficient to enable me to hire a canoe for any great distance; and I had but little hopes of subsisting by charity, in a country where the Moors have such influence. But above all, I perceived that I was advancing more and more within the power of those merciless fanatics; and from my reception both at SEGO and SANSANDING (see these articles, *Suppl.*), I was apprehensive that, in attempting to reach even Jenné (unless under the protection of some man of consequence amongst them, which I had

no

Sillon || Siwa

no means of obtaining), I should sacrifice my life to no purpose; for my discoveries would perish with me. The prospect either way was gloomy. In returning to the Gambia, a journey on foot of many hundred miles presented itself to my contemplation, through regions and countries unknown. Nevertheless, this seemed to be the only alternative; for I saw inevitable destruction in attempting to proceed to the eastward. With this conviction on my mind, I hope my readers will acknowledge that I did right in going no farther. I had made every effort to execute my mission in its fullest extent which prudence could justify. Had there been the most distant prospect of a successful termination, neither the unavoidable hardships of the journey, nor the dangers of a second captivity, should have forced me to desist. This, however, necessity compelled me to do; and whatever may be the opinion of my general readers on this point, it affords me inexpressible satisfaction, that my honourable employers have been pleased, since my return, to express their full approbation of my conduct." He would be a very unreasonable man, indeed, who could on this point think differently from Mr Park's employers. Silla is placed in the new map of Africa in about 14° 48′ N. Lat. and 1° 24′ W. Long.

SILLON, in fortification, an elevation of earth, made in the middle of the moat, to fortify it, when too broad. It is more usually called the *envelope*.

SIMANCAS, a village on the eastern limit of the kingdom of Leon in Spain, two leagues below Valladolid, on the river Gisuerga. It is mentioned by Dr Robertson in the introduction to his History of America, and is remarkable for the archives or register office of the kingdoms of Leon and Castile, kept in the castle there. This collection was begun when the kings resided often at Valladolid; in which city to this day is the chancery or civil and criminal tribunal for almost all Spain to the north of the Tagus. It was thought convenient to have those papers kept in the neighbourhood of that court; and this castle was particularly fit for that purpose, as it is all built of stone. Some years ago there were two large halls in this office filled with papers relating to the first settlement of the Spaniards in South America. There was also in the room called the *ancient royal patronage* a box containing treaties with England, in which are many letters and treaties between the kings of England and Spain from about the year 1400 down to 1600. There was also in the same archives a strong box, with five locks, which, it is said, has not been opened since the time of Philip II. and it is conjectured that it contains the process against Philip's son Prince Charles. But it seems some of the state papers have been removed to Madrid.

SITUS, in algebra and geometry, denotes the situation of lines, surfaces, &c. Wolfius delivers some things in geometry, which are not deduced from the common analysis, particularly matters depending on the *situs* of lines and figures. Leibnitz has even founded a particular kind of analysis upon it, called *calculus situs*.

SIWA, a town in Egypt, to the westward of Alexandria, built on a small fertile spot or Oasis, which is surrounded on all sides by desert land. A large proportion of this space is filled with date trees; but there are also pomegranates, figs, and olives, apricots, and plantains; and the gardens are remarkably flourishing. They cultivate a considerable quantity of rice, which, however, is of a reddish hue, and different from that of the Delta. The remainder of the cultivable land furnishes wheat enough for the consumption of the inhabitants. Water, both salt and fresh, abounds; but the springs which furnish the latter are most of them tepid; and such is the nature of the water, air, and other circumstances, that strangers are often affected with agues and malignant fevers.

The greatest curiosity about Siwa is a ruin of undoubted antiquity, which, according to Mr Browne, resembles too exactly those of the Upper Egypt, to leave a doubt that it was erected and adorned by the same intelligent race of men. The figures of Isis and Anubis are conspicuous among the sculptures; and the proportions are those of the Egyptian temples, though in miniature. What of it remains is a single apartment, built of massy stones, of the same kind as those of which the pyramids consist; and covered originally with six large and solid blocks, that reach from one wall to the other. The length is 32 feet in the clear, the height about 18, the width 15. A gate, situated at one extremity, forms the principal entrance; and two doors, also near that extremity, open opposite to each other. The other end is quite ruinous; but, judging from circumstances, it may be imagined that the building has never been much larger than it now is. There is no appearance of any other edifice having been attached to it, and the less so as there are remains of sculpture on the exterior of the walls. In the interior are three rows of emblematical figures, apparently designed to represent a procession; and the space between them is filled with hieroglyphic characters, properly so called. The people of Siwa have no [illegible] concerning this edifice, nor attribute to it [illegible]y, but that of concealing treasures, a[illegible] of demons. It has, however, been [illegible]h some degree of probability, that Siwa is the [illegible]m of Pliny, and that this building was coeval wit[illegible] famous temple of Jupiter Ammon, and a depend[illegible] on it. This may be so; but neither the natives [illegible] Siwa, nor the various tribes of Arabs who frequent that place, know any thing of the ruins of that temple, about which Mr Browne made every possible enquiry. "It may (as he observes) still survive the lapse of ages, yet remain unknown to the Arabs, who traverse the wide expanse of the desert; but such a circumstance is scarcely probable. It may be completely overwhelmed in the sand; but this is hardly within the compass of belief."

The complexion of the people of Siwa is generally darker than that of the Egyptians. Their dialect is also different. They are not in the habitual use either of coffee or tobacco. Their sect is that of Malik. The dress of the lower class is very simple, they being almost naked: among those whose costume was discernible, it approaches nearer to that of the Arabs of the desert than of the Egyptians or Moors. Their clothing consists of a shirt of white cotton, with large sleeves, and reaching to the feet; a red Tunisine cap, without a turban; and shoes of the same colour. In warm weather they commonly cast on the shoulder a blue and white cloth, called in Egypt *melayé*; and in winter they are defended from the cold by an *ihhram* or blanket. The list of their household furniture is very short; some earthen ware made by themselves, and a few mats, form the chief part of it, none but the richer order being

being poſſeſſed of copper utenſils. They occaſionally purchaſe a few ſlaves from the Murzouk caravan. The remainder of their wants is ſupplied from Cairo or Alexandria, whither their dates are tranſported, both in a dry ſtate and beaten into maſh, which when good in ſome degree reſembles a ſweet meat. They eat no large quantity of animal food; and bread of the kind known to us is uncommon. Flat cakes, without leaven, kneaded, and then half baked, form part of their nouriſhment. The remainder conſiſts of thin ſheets of paſte, fried in the oil of the palm tree, rice, milk, dates, &c. They drink in great quantities the liquor extracted from the date-tree, which they term *date tree water*, though it have often, in the ſtate they drink it, the power of inebriating. Their domeſtic animals are, the hairy ſheep and goat of Egypt, the aſs, and a very ſmall number of oxen and camels. The women are veiled, as in Egypt. After the rains, the ground in the neighbourhood of Siwa is covered with ſalt for many weeks. Siwa is ſituated in 29° 12′ N. Lat. and 44° 54′ E. Long.

SKIRMISH BAY, the name given by Lieutenant Broughton to a bay in an iſland, which was diſcovered by him in latitude 43° 48′ ſouth, and in longitude 183° eaſt. The Chatham armed tender, which Mr Broughton commanded, under Captain Vancouver in his voyage of diſcovery, worked up into the bay, and came to anchor about a mile from the ſhore. The Lieutenant, the maſter, and one of the mates, landed, and found the people ſo extremely inhoſpitable, that they were obliged to fire upon them in their own defence. The land, whether iſland or continent, is of conſiderable magnitude; the part which they ſaw extended nearly 40 miles from eaſt to weſt; and the appearance of the country, according to the deſcription given, is very promiſing. In many reſpects the natives reſemble thoſe of New Zealand; from which country they are diſtant about 100 leagues; but their ſkins were deſtitute of any marks, and they had the appearance of being cleanly in their perſons. Their dreſſes were of ſeal or ſea-bear ſkin, and ſome had fine woven mats faſtened round the waiſt. "They ſeemed a cheerful race; our converſation (ſays Mr Broughton) frequently exciting violent burſts of laughter amongſt them. On our firſt landing, their ſurpriſe and exclamations can hardly be imagined; they pointed to the ſun, and then to us, as if to aſk, whether we had come from thence?" Their arms were ſpears, clubs, and a ſmall weapon reſembling the New Zealand patoo.

SLIDING-RULE (ſee that article, as likewiſe GAUGING-*Rod*, GEOMETRY, and *Logarithmic Lines*, Encycl.) is introduced here, for the ſake of a new, and (except in working direct proportions) a more commodious method than the common, of applying the ſlider. This method, which is propoſed by the Rev. W. Pearſon of Lincoln, is as follows:

Invert the ſlider B on any common ſliding rule, whereby the numerical figures will aſcend on it, and on the fixed line A, in contrary directions: now, as the diſtance from unity to any multiplier, on Gunter's line, will invariably extend from any multiplicand to their product, it follows, that if any particular number on the inverted ſlider B be placed oppoſite to any other given number on A, the product of thoſe numbers will ſtand on the ſlider B, againſt unity on A; for, in any poſition of the inverted ſlider, the diſtance from unity to the multiplier on A, inſtead of being carried forward on B, as when the ſlider is in a direct poſition, is brought back thereby to unity again; ſo that unity (or *ten* on ſingle lines where the ſlider is too ſhort for the operation) is invariably the index for the product of any two coincident numbers throughout the lines.

In diviſion, by the ſame proceſs, if the dividend on B be put to the index, or unity on A, the diviſion and quotient will coincide on the two oppoſite lines; ſo that when one is given, and ſought for on either line, the other is ſeen on its oppoſite line at the ſame time.

The next operation which offers itſelf here is reciprocal proportion, which can be effected by no other method than by inverting the ſlider, but which is rendered as eaſy by this application, as direct proportion is in the common way; for if any antecedent number on B inverted be ſet to its conſequent on A, any other antecedent on B, in the ſame poſition, will ſtand againſt its conſequent on A, ſo as that the terms may be in a reciprocal ratio. In ſquaring any number, it will appear, from what has been already ſaid, that if the number to be ſquared be placed on B, inverted againſt the ſame on A, the ſquare will ſtand on B, againſt unity on A. Therefore, to extract the ſquare root of any number, let that number on B ſtand againſt unity on A; and then wherever the coincident numbers are both of the ſame value, that point indicates the root. If two dividing lines of the ſame value do not exactly coincide, the coincident point will be at the middle of the ſpace contained between thoſe two which are neareſt a coincidence; and as there is only one ſuch point, there can be no miſtake in readily aſcertaining it. The finding of a mean proportional between any two numbers is extremely eaſy at one operation; for if one of the numbers on B inverted be ſet to the other on A, the coincident point of two ſimilar numbers ſhews either of thoſe to be the mean, or ſquare root of their product, according to the preceding proceſs. Thus have we a ſhort and eaſy method of multiplying, dividing, working reciprocal proportion, ſquaring and extracting the ſquare root, at one poſition of the inverted ſlider, whereby the eye is directed to only one point of view for the reſult, after the ſlider is fixed: whereas, by the common method of extracting the ſquare root by A and B direct, the ſlider requires to be moved backwards and forwards by adjuſtment, the eye moving alternately to two points, till ſimilar numbers ſtand, one on B againſt unity on A, and the other on A againſt the ſquare number on B; which ſquare number, in the caſe of finding a mean proportional, muſt be found by a previous operation. Hence, for more convenience in the extraction of roots, and meaſuring of ſolids, an additional line called D has been added to the rule, which renders it more complex, and conſequently ſeldom underſtood by an artificer.

SNOW. See that article (*Encycl.*), where we have endeavoured to account for ſnow's contributing to the preſervation and growth of vegetables. It muſt be confeſſed, however, that if ſnow poſſeſſed only the property of preſerving vegetables, and of preventing them from periſhing by the ſeverity of the cold, it is not at all probable that the ancient philoſophers would have conſidered it as depoſiting on the earth nitrous ſalts, as they might have aſcertained, by a very ſimple experiment,

ment, that it contains none of that salt; for they did not ascribe the same property to rain-water, but they remarked that snow burnt the skin in the manner of acids, as well as other bodies immersed in it. Being induced to conclude that there was nitre in the air, it was natural that they should ascribe to this nitre the burning qualities of snow, and consequently its influence on vegetation.

Such reflections induced Morveau, *alias* Citizen Guyton, to employ J. H. Hassenfratz to inquire into the cause of the difference of the effects of snow and rain-water on various substances. Hassenfratz found that these differences are occasioned by the oxygenation of the snow; and that these effects are to be ascribed to a particular combination of oxygen in this congealed water. He put 1000 grammes of snow in a jar, and 1000 grammes of distilled water in another. He poured into each of the jars an equal quantity of the same solution of turnsole. He placed both the jars in a warm temperature; and after the snow melted, he remarked that the dye was redder in the snow water than in the distilled water. He repeated this experiment, and with the same result. He put into a jar 1000 grammes of distilled water, and into another 1000 grammes of snow. Into each of the jars he put 6·5 grammes of very pure and clean sulphat of iron. In the first, there was precipitated 0·150 grammes of the oxyd of iron, and 0·010 grammes in the other. As the oxyd of iron was precipitated from a solution of the sulphat by oxygen, it thence follows, that the snow contained more oxygen than the distilled water; and it follows, from the first experiment, that this quantity of oxygen was considerable enough to redden the tincture of turnsole.

It is fully demonstrated by these two experiments, that snow is oxygenated water, and that it must consequently have on vegetation an action different from that of common ice. The experiments of Dr Ingenhousz on the germination of seeds have taught us, that the presence and contact of oxygen are absolutely necessary for the plant to expand. They have shewn also, that the more abundant the oxygen is, the more rapidly will the seeds grow. Most plants suffered to attain to their perfect maturity shed on the earth a part of their seed. These seeds, thus abandoned and exposed to the action of cold, are preserved by the snow which covers them, at the same time that they find in the water it produces by melting, a portion of oxygen that has a powerful action on the principle of germination, and determines the seeds that would have perished to grow, to expand, and to augment the number of the plants that cover the surface of the earth.

A very considerable number of the plants which are employed in Europe for the nourishment of men, are sown in the months of September, October, and November. The seeds of several of these germinate before the cold commences its action upon them, and changes the principle of their life. The snow which covers the rest, acting on the germ by its oxygenation, obliges them to expand, and to increase the number of useful plants which the farmer and gardener commit to the earth, and consequently to multiply their productions.

Here, then, we have three effects of snow upon vegetation, all very different, which contribute each separately to increase, every year, the number of our plants, to give them more vigour, and consequently to multiply our crops. These effects are: 1. To prevent the plants from being attacked by the cold, and from being changed or perishing by its force. 2. To furnish vegetables with continual moisture, which helps them to procure those substances necessary for their nutrition, and to preserve them in a strong healthy state. 3. To cause a greater number of seeds to germinate, and consequently to increase the number of our plants.

Snow, Soldering.

SOAP. See Chemistry *Index*, Suppl.

SOLDERING. Under this title, in the *Encyclopædia*, we have given directions for soldering silver, brass, and iron: but there are other metals which must sometimes be soldered; and the following account of different solders, taken from the *Philosophical Magazine*, may be useful to many of our readers.

"When lead, tin, and bismuth, are mixed in a certain proportion, they produce a metal exceedingly fusible, which is known by the name of *soft solder*; but which, from its singular properties, may be applied with advantage to many other useful purposes. Newton, and after him Kraft and Muschenbroek, observed, that five parts of bismuth, three of tin, and two of lead, also five parts of bismuth, four of tin, and one part of lead, melted with a heat of 220 degrees of Fahrenheit; and they found that various mixtures of this kind were fusible by a heat not much greater than that of boiling water. At a later period, V. Rose, a German naturalist, discovered, that a mixture of four parts of bismuth, two of tin, and two of lead, as Kunkel recommended for soldering tin; and D'Arcet, among the French, that a mixture of eight parts of bismuth, three of tin, and five of lead; or eight of bismuth, four of tin, and four of lead; or eight of bismuth, two of tin, and six of lead; also sixteen of bismuth, seven of tin, and nine of lead—all melted, or at least became soft, in boiling water.

"According to the experiments made by Professor Gmelin, respecting the fusion of these three metals, a mixture, consisting of two parts of bismuth, one part of tin, and one of lead, which is the same as Rose proposed, gave a metal that was fused in boiling water. A mixture of six or more parts of bismuth, six of tin, and three of lead, or one part of bismuth, two parts of tin, and two of lead, gave, according to Klein, the solder used by the tin button makers. The same workmen use also for soldering, according to Klein, a mixture of four parts of bismuth, three parts of tin, and five parts of lead. Among the many soft solders employed by the tin-men, a mixture of one part of bismuth, two parts of tin, and one part of lead, is, according to Klein, very much employed. Respecting this kind of solder, the experiments of Professor Gmelin give the following result: One part of bismuth, two parts of tin, and one part of lead, melt in boiling water. According to Klein, the tin-men employ for soldering a mixture of one part of bismuth, twenty four parts of tin, and four parts of lead. Eight parts of bismuth, three of tin, and five of lead, gave a metal exceedingly like tin in its colour and brightness, but very brittle; in water beginning to boil, it became not only soft, but was completely fused. This imitation, however, may be better accomplished by the mixture of Professor Lightenberg, which consists of five parts of bismuth, three

Soldering, Soudan.

three of tin, and two of lead. This metal is very like the former, though not so brittle; but it seemed to melt in hot water even before it came to boil."

As this subject has again come under our notice, it may be proper to lay before our readers what M. Van Braam says of the Chinese method of soldering frying-pans and other vessels of cast-iron, when cracked and full of holes. As the author admits that it *must* appear *impossible* to those who have not *witnessed* the process, such of our artists as have not been in China will give to the tale what credit they think it deserves.

"All the apparatus of the workman consists in a little box, 16 inches long and 6 wide, and 18 inches in depth, divided into two parts. The upper contains three drawers with the necessary ingredients; in the lower is a bellows, which when a fire is wanted is adapted to a furnace eight inches long and four inches wide. The crucibles for melting the small pieces of iron intended to serve as solder are a little larger than the bowl of a common tobacco pipe, and of the same earth of which they are made in Europe: thus the whole business of soldering is executed.

"The workman receives the melted matter out of the crucible upon a piece of *wet paper*, approaches it to one of the holes or cracks in the frying-pan, and applies it there, while his assistant smooths it over by scraping the surface, and afterwards rubs it with a bit of *wet linen*. The number of crucibles which have been deemed necessary are thus successively applied, in order to stop up all the holes with the melted iron, which consolidates and [illegible] with the broken utensil, and which [illegible]. SOUDAN, [illegible] ne- [illegible] the name of [illegible] DAR-FUR. We [illegible] by any [illegible] Mr Browne, who [illegible] between the 13th and 16th degrees of north latitude, and between the 26th and 30th degrees of east longitude. These numbers are not exact; it does not reach so far east as the 30th degree, nor so far north as the 16th; but on his map minutes are not marked. On the north, it is bounded by a desert which separates it from Egypt; on the east, by Kordofan, which is now subject to Soudan, and lies between it and Sennaar; and on the south and east, by countries of which the names are hardly known. Mr Browne was induced to visit Soudan in hopes of being able to trace the Bahr-el-abiad, or true Nile, to its source: but he was disappointed; for that river rises in mountains considerably farther south than the limits of this kingdom; and the Sultan, a cruel and capricious tyrant, detained him a prisoner at large almost three years.

Soudan, or Dar-fur, abounds with towns or villages, ill built, of clay, and none of them very large. Of these it is not worth while to give an account. Its seasons are divided into rainy and dry. The perennial rains, which fall in Dar-Fur from the middle of June till the middle of September in greater or less quantity, but generally both frequent and violent, suddenly invest the face of the country, till then dry and steril, with a delightful verdure. Except where the rocky nature of the soil absolutely impedes vegetation, wood is found in great quantity; nor are the natives assiduous completely to clear the ground, even where it is designed for the cultivation of grain. As soon as the rains begin, the proprietor, and all the assistants that he can collect, go out to the field; and having made holes at about two feet distance from each other, with a kind of hoe, over all the ground he occupies, the *dokn*, a kind of millet, is thrown into them, and covered with the foot, for their husbandry requires not many instruments. The time for sowing the wheat is nearly the same. The *dokn* remains scarcely two months before it is ripe; the wheat about three.

Soudan.

The animals in Soudan, both wild and tame, are the same as in other parts of Africa in the same latitude. Though the Furians breed horses, and purchase very fine ones in Dongola, and from the Arabs to the east of the Nile, the ass is more used for riding; and an Egyptian ass (for the asses of Dar-Fur are diminutive and indocile like those of Britain) fetches from the value of one to that of three slaves. The villages of this country, like those of Abyssinia, are infested with hyenas; and in the unfrequented parts of the country are the elephant, the rhinoceros, the lion, the leopard, and all the other quadrupeds of Africa. The Arabs often eat the flesh of the lion and the leopard; and sometimes they so completely tame those animals, as to carry them loose into the market place. Our author tamed two lions, of which one acquired most of the habits of a dog. He satiated himself twice a week with the offal of the butchers, and then commonly slept for several hours successively. When food was given them, they both grew ferocious towards each other, and towards any one who approached them. Except at that time, though both were males, he never saw them disagree, nor shew any sign of ferocity towards the human race. Even lambs passed them unmolested.

Among the birds, the *vultur perenopterus*, or white-headed vulture, is most worthy of notice. It is of surprising strength, and is said by the natives to be very long-lived, *sed fides penes auctores*. "I have lodged (says Mr Browne) a complete charge of large shot, at about 50 yards distance, in the body of this bird: it seemed to have no effect on him, as he flew to a considerable distance, and continued walking afterwards. I then discharged the second barrel, which was loaded with ball: this broke his wing; but on my advancing to seize him, he fought with great fury with the other. There are many thousands of them in the inhabited district. They divide the field with the hyena: what carrion the latter leaves at night, the former come in crowds to feed on in the day. Near the extremity of each wing is a horny substance, not unlike the spur of an old cock. It is strong and sharp, and a formidable instrument of attack. Some fluid exudes from this bird that smells like musk; but from what part of him I am uncertain." The serpents found in Soudan are the same as in Egypt; but the natives have not the art of charming them, like the Egyptians. The locust of Arabia is very common, and is frequently roasted and eaten, particularly by the slaves.

In Dar-Fur there seems to be a scarcity of metals; but

Soudan. but in its neighbourhood to the south and west all kinds are to be found. The copper brought by the merchants from the territories of certain idolatrous tribes bordering on Fur, is of the finest quality, in colour resembling that of China, and appears to contain a portion of zinc, being of the same pale hue. Iron is found in abundance; but they have not yet learned the art of converting it into steel. Silver, lead, and tin, our author never heard mentioned in Soudan, but as coming from Egypt; but of gold, in the countries to the east and west, the supply is abundant. Alabaster, and various kinds of marble, are found within the limits of Fur, as is fossil salt within a certain district; and there is a sufficient supply of nitre, of which, however, no use is made.

The restraint under which Mr Browne was kept in this inhospitable country, prevented him from making a full catalogue of its vegetable productions. Of the trees which shade our forests or adorn our gardens in Europe, very few exist in Dar-Fur. The characteristic marks of those species which most abound there, are their sharp thorns, and the solid and unperishable quality of their substance. They seem to be much the same as those which Bruce found in Abyssinia. There is a small tree called *enneb*, to the fruit of which they have given the name of grapes. It bears leaves of light green hue; and the fruit, which is of a purple colour, is attached, not in bunches, but singly to the smaller branches, and interspersed among the leaves. The internal structure of the fruit is not very unlike the grape, which it also resembles in size: but the pulp is of a red hue, and the taste is strongly astringent. The water-melon (*cucurbita citrulius*) grows wild over almost all the cultivable lands, and ripens as the corn is removed. In this state it does not attain a large size. The inside is of a pale hue, and has little flavour. As it ripens, the camels, asses, &c. are turned to feed on it, and it is said to fatten them. The seeds, as they grow blackish, are collected to make a kind of tar, *kutran*. Those plants of the melon which receive artificial culture grow to a large size, and are of exquisite flavour. Tobacco is produced in abundance; and our author speaks of cochineal as found in Dar-Fur, or some of the neighbouring countries.

The harvest is conducted in a very simple manner. The women and slaves of the proprietor are employed to break off the ears with their hands, leaving the straw standing, which is afterwards applied to buildings and various other useful purposes. They then accumulate them in baskets, and carry them away on their heads. When thrashed, which is aukwardly and incompletely performed, they expose the grain to the sun till it become quite dry; after this a hole in the earth is prepared, the bottom and sides of which are covered with chaff to exclude the vermin. This cavity or magazine is filled with grain, which is then covered with chaff, and afterwards with earth. In this way the maize is preserved tolerably well. In using it for food, they grind it, and boil it in the form of polenta, which is eaten either with fresh or sour milk, or still more frequently with a sauce made of dried meat pounded in a mortar, and boiled with onions, &c. The Furians use little butter; with the Egyptians and Arabs it is an article in great request. There is also another sauce which the poorer people use and highly relish; it is composed of an herb called *cowel* or *cawel*, of a taste in part acescent and in part bitter, and generally disagreeable to strangers. Soudan.

The magistracy of one, which seems tacitly, if it be not expressly, favoured by the dispensation of Mohammed, as in most other countries professing that religion, prevails in Dar-Fur. The monarch indeed can do nothing contrary to the Koran, but he may do more than the laws established thereon will authorise; and as there is no council to controul or even to assist him, his power may well be termed despotic. He speaks in public of the soil and its productions as his personal property, and of the people as little else than his slaves.

His power in the provinces is delegated to officers, who possess an authority equally arbitrary. In those districts, which have always, or for a long time, formed an integral part of the empire, these officers are generally called *Meleks*. In such as have been lately conquered, or, perhaps more properly, have been annexed to the dominion of the Sultan under certain stipulations, the chief is suffered to retain the title of Sultan, yet is tributary to and receives his appointment from the Sultan of Fur.

Despotic and arbitrary as he is, the Sultan here does not seem wholly inattentive to that important object, agriculture. Nevertheless, it may be esteemed rather a blind compliance with ancient custom, than individual public spirit, in which has originated a practice adopted by him, in itself sufficiently laudable, since other of his regulations by no means conduce to the same end. At the beginning of [illegible] wet season, which is also the moment for sowing the corn, the king goes out with his Meleks, and [illegible] and while the people are employed [illegible] ground and sowing the seed, he [illegible] several holes with his own hand. The same custom, it is said, obtains in Bornou and other countries in this part of Africa. It calls to the mind a practice of the Egyptian kings mentioned by Herodotus.

The population of Dar-Fur is not large. An army of 2000 men was spoken of, when Mr Browne was in the country, as a great one; and he does not think that the number of souls within the empire can much exceed 200,000. The troops of this country are not famed for skill, courage, or perseverance. In their campaigns, much reliance is placed on the Arabs who accompany them, and who are properly tributaries rather than subjects of the Sultan. One energy of barbarism they indeed possess in common with other savages, that of being able to endure hunger and thirst; but in this particular they have no advantage over their neighbours. In their persons the Furians are not remarkable for cleanliness. Though observing as Mahommedans all the superstitious formalities of prayer, their hair is rarely combed, or their bodies completely washed. The hair of the pubes and axillæ it is usual to exterminate; but they know not the use of soap; so that with them polishing the skin with unguents holds the place of perfect ablutions and real purity. A kind of farinaceous paste is however prepared, which being applied with butter to the skin, and rubbed continually till it become dry, not only improves its appearance, but removes from it accidental sordes, and still more the effect of continued transpiration, which, as there are no baths in the country, is a consideration of some importance.

Soudan.

ance. The female slaves are dexterous in the application of it; and to undergo this operation is one of the refinements of African sensuality.

Nothing resembling current coin is found in Soudan, unless it be certain small tin rings, the value of which is in some degree arbitrary. The Austrian dollars, and other silver coins brought from Egypt, are all sold as ornaments for the women.

The disposition of the Furians is cheerful; and that gravity and reserve which the precepts of Mahommedism inspire, and the practice of the greater number of its professors countenances and even requires, seems by no means as yet to sit easy on them. A government perfectly despotic, and not ill administered, as far as relates to the manners of the people, yet forms no adequate restraint to their violent passions. Prone to inebriation, but unprovided with materials or ingenuity to prepare any other fermented liquor than *buza*, with this alone their convivial excesses are committed. But though the Sultan published an ordnance (March 1795), forbidding the use of that liquor under pain of death, the plurality, though less publicly than before, still indulge themselves in it. A company often sits from sunrise to sun-set, drinking and conversing, till a single man sometimes carries off near two gallons of that liquor. The buza has, however, a diuretic and diaphoretic tendency, which precludes any danger from these excesses. In this country dancing is practised by the men as well as the women, and they often dance promiscuously.

The vices of thieving, lying, and cheating in bargains, with all others [illegible] allied to them, [illegible] under the same circumstances, [illegible]. No property, whether [illegible] out of the sight of the owner, [illegible] it, unless he be [illegible] selling, the pa- [illegible] for the pa- [illegible] [illegible] to the [illegible] false- [illegible]

The privilege of polygamy, which, as is well known, belongs to their religion, the people of Soudan push to the extreme. By their law, they are allowed four free women, and as many slaves as they can maintain; but the Furians take both free women and slaves without limitation. The Sultan has more than a hundred free women, and many of the Meleks have from twenty to thirty. In their indulgence with women, they pay little regard to restraint or decency. The form of the houses secures no great secrecy to what is carried on within them; yet even the concealment which is thus offered is not always sought. The shade of a tree, or long grass, is the sole temple required for the sacrifices to the Cyprian goddess. In the course of licentious indulgence, father and daughter, son and mother, are sometimes mingled; and the relations of brother and sister are exchanged for closer intercourse.

Previously to the establishment of Islamism * and kingship, the people of Fur seem to have formed wandering tribes; in which state many of the neighbouring nations to this day remain. In their persons they differ from the negroes of the coast of Guinea. Their hair is generally short and woolly, though some are seen with it of the length of eight or ten inches, which they esteem a beauty. Their complexion is for the most part perfectly black. The Arabs, who are numerous within the empire, retain their distinction of feature, colour, and language. They most commonly intermarry with each other. The slaves, which are brought from the country they call *Fertit* (land of idolaters), perfectly resemble those of Guinea, and their language is peculiar to themselves.

Soudan; Souffriere.

The revenues of the crown consist of a duty on all merchandise imported, which, in many instances, amounts to near a tenth; of a tax on all slaves exported to Egypt; of all forfeitures for misdemeanors; of a tenth on all merchandise, especially slaves, brought from every quarter but Egypt, and when slaves are procured by force, this tenth is raised to a fifth; of a tribute paid by the Arabs, who breed oxen, horses, camels, sheep; of a certain quantity of corn paid annually by every village; besides many valuable presents, which must be paid by the principal people, both at stated times and on particular occasions. Add to all this, that the king is chief merchant in the country; and not only dispatches with every caravan to Egypt a great quantity of his own merchandise, but also employs his slaves and dependents to trade with the goods of Egypt on his own account, in the countries adjacent to Soudan.

The commodities brought by the caravans from Egypt are, 1. Amber beads. 2. Tin, in small bars. 3. Coral beads. 4. Cornelian beads. 5. False cornelian beads. 6. Beads of Venice. 7. Agate. 8. Rings, silver and brass, for the ancles and wrists. 9. Carpets, small. 10. Blue cotton cloths of Egyptian fabric. 11. White cotton ditto. 12. Indian muslins and cottons. 13. Blue and white cloths of Egypt, called *Melayes*. 14. Sword-blades, strait (German), from Cairo. 15. Small looking-glasses. 16. Copper face-pieces, or defensive armour for the horses heads. 17. Fire arms. 18. Kohhel for the eyes. 19. Rhea, a kind of moss from European Turkey, for food and a scent. 20. *She*, a species of absynthium, for its odour, and as a remedy: both the last sell to advantage. 21. Coffee. 22. *Mahleb*, *Krumphille*, *Symlille*, *Sandal*, nutmegs. 23. *Dufr*, the shell of a kind of fish in the Red Sea, used for a perfume. 24. Silk unwrought. 25. Wire, brass and iron. 26. Coarse glass beads, made at Jerusalem, called *hersh* and *munjur*. 27. Copper culinary utensils, for which the demand is small. 28. Old copper for melting and reworking. 29. Small red caps of Barbary. 30. Thread linens of Egypt—small consumption. 31. Light French cloths, made into benishes. 32. Silks of Scio, made up. 33. Silk and cotton pieces of Aleppo, Damascus, &c. 34. Shoes of red leather. 35. Black pepper. 36. Writing paper (*papier des trois lunes*), a considerable article. 37. Soap of Syria.

The goods transported to Egypt are, 1. Slaves, male and female. 2. Camels. 3. Ivory. 4. Horns of the rhinoceros. 5. Teeth of the hippopotamus. 6. Ostrich feathers. 7. Whips of the hippopotamus's hide. 8. Gum. 9. Pimento. 10. Tamarinds, made into round cakes. 11. Leather sacks for water (*ray*) and dry articles (*geraub*). 12. Peroquets in abundance, and some monkeys and Guinea fowls. 13. Copper, white, in small quantity.

SOUFFRIERE, a small town, situated at the bottom of a bay, towards the leeward extremity of the island of St Lucia. There is nothing in the town itself which

could

Souffriere, Sound.

could have entitled it to notice in this work; but the ground about it is very remarkable. It has been described by different authors; and our readers will probably not be ill pleased with the following description of this wonderful spot by Dr Rollo.

"Souffriere (says he) is surrounded by hills covered with trees, the declivities of which, and every part capable of produce, are cultivated, and afford good sugar-cane. This place has its marshes, but not so extensive, or so much to windward as those about Carenage.

"The extremity of the south side of Souffriere Bay runs into two steep hills of a conical figure, which are nearly perpendicular: they are reckoned the highest on the island, and are known by the name of the *Sugar-Loaf Hills*. From their height and straitness it is impossible to ascend them: we were told it was once attempted by two negroes, but they never returned. They are covered with trees and shrubs, and are the shelter of goats, several of which sometimes descend, and are shot by the natives.

"After you pass the hills to windward of Souffriere, a fine clear and level country presents itself. From the back of the Sugar Loaf Hills, and all along the sea-coast, to the distance, we suppose, of from fifteen to twenty miles, this flat or level extends: it is all cultivated and divided into rich estates, affording sugar-cane equal to any in our islands. This beautiful spot is intersected by many rivers of very clear water, and these are conducted by art to the purpose of sugar making. The rains in this part are less frequent than on any other part of the island; however, they have often a proportion more than sufficient. The wind here blows from the sea, or nearly so.

"We cannot finish this description without taking notice of a volcano in the neighbourhood of Souffriere. You pass over one or two small hills to the southward of the town, and before any mark of the place is perceived you are sensible of the smell of sulphur. The first thing you discern is a rivulet of black running water, sending forth steams as if nearly boiling. From the prospect of this you soon open on the volcano, which appears in a hollow, surrounded close on every side by hills. There are only two openings; the one we entered, and another almost opposite to it on the north side. In the hollow there are many pits of a black and thick boiling matter, which seems to work with great force. Lava is slowly thrown out; and in the centre of the hollow there is a large mass of it, forming a kind of hill. This we ascended; but were soon obliged to return from the excessive heat. The lava is a sulphur mixed with a calcareous earth and some saline body. We found small quantities of alum in a perfect state. In the opening, at the north side of the hollow, there is a rivulet of very good water. On stirring the bottom, over which this water runs, we were surprised with feeling it very hot; and on placing a tumbler filled with some of the water close to the bottom of the rivulet, it soon became so hot as not to be touched. The liquid which runs from the pits is strongly impregnated with sulphur, and resembles a good deal the preparation sold in the shops, known by the name of *aqua sulphurata*, or *gas sulphuris*."

SOUND-BOARD, the principal part of an organ, and that which makes the whole machine play. This sound-board, or summer, is a reservoir into which the wind, drawn in by the bellows, is conducted by a port-vent, and thence distributed into the pipes placed over the holes of its upper part. This wind enters them by valves, which open by pressing upon the stops or keys, after drawing the registers, which prevent the air from going into any of the other pipes beside those it is required in.

Sound. ‖ Spallanzani.

Sound Board denotes also a thin broad board placed over the head of a public speaker, to enlarge and extend or strengthen his voice.

Sound-boards, in theatres, are found by experience to be of no service; their distance from the speaker being too great to be impressed with sufficient force. But sound boards immediately over a pulpit have often a good effect, when the case is made of a just thickness, and according to certain principles.

Sound-Post, is a post placed withinside of a violin, &c. as a prop between the back and the belly of the instrument, and nearly under the bridge.

SOWAL, in the language of Bengal, a question or request.

SPALLANZANI (Lazarus), was born at Scandiano, in the dutchy of Modena, on the 10th of January 1729. He was son of Jean Nicholas Spallanzani, an esteemed jurisconsult, and of Lucia Zugliani. He commenced his studies in his own country, and at the age of fifteen years went to Reggio de Modena in order to continue them. The Jesuits, who instructed him in the belles lettres, and the Dominicans, who heard of his progress, were ea[illegible] attaching him to them; but his pass[illegible] extending his knowledge led him to Bologna, where [illegible] Laura Bassi, a woman justly celebrated for [illegible] and her skill in natural philosophy [illegible] was one of the most illustrious [illegible] of the Institute and of Italy. [illegible] he learned to prefer [illegible] commentators, and to judge of the value of the commentary by its resemblance to the original. He instantly availed himself of the wisdom of that lady's counsels, and was not [illegible] before he experienced the happy effects of it. How agreeable it is to see him in 1765 painting his gratitude for his instructor, to whom he dedicated a Latin dissertation at that time, in which he mentions the applause that Laura Bassi received at Modena, when she entered the auditory of her pupil, then become professor. The taste of Spallanzani for philosophy was not exclusive; he already thought, like all great men, that the study of antiquity and the belles lettres was requisite to give to ideas that clearness, to expressions that accuracy, and to reasonings that connection, without which the finest thoughts become barren. He studied his own language with care, and perfected himself in the Latin tongue; but above all, he attached himself to the Greek and the French. Homer, Demosthenes, St Basil, were his favourite authors. Spallanzani applied himself to jurisprudence at the instance of a father whom he tenderly loved: he was upon the point of receiving the degree of doctor of civil law, when Anthony Vallisneri, professor of natural history at Padua, persuaded him to renounce this vocation, by promising to obtain the consent of his father, who was sensibly touched by his son's devotion to his will, and who thereby left him at liberty to follow his own inclinations. From that moment he gave himself

up

Spallanzani.

up with more ardour than ever to the study of mathematics, continuing that also of the living and dead languages.

Spallanzani was presently known all over Italy, and his own country was the first to do homage to his talents The university of Reggio, in 1754, chose him to be professor in logic, metaphysics, and Greek. He taught there for ten years; and during that period consecrated all the time he could spare from his lessons to the observation of Nature. Now and then an accidental discovery would increase his passion for natural history, which always augmented by new successes. His observations upon the animalculæ of infusions fixed the attention of Haller and of Bonnet; the latter of whom assisted him in his glorious career, and thenceforth distinguished him as one of the learned interpreters of Nature.

In 1760 Spallanzani was called to the university of Modena; and although his interest would have made him accept the advantageous offers of the university of Coimbra, of Parma, and of Cesena; yet his patriotism and his attachment to his family confined his services to his own country. The same considerations engaged him to refuse the propositions made him by the academy of Petersburg some years after. He remained at Modena till the year 1768, and he saw raised by his care a generation of men constituting at this time the glory of Italy. Among them may be counted *Venturi*, professor of natural philosophy at Modena; *Belloni*, bishop of Carpi; *Lucchesini*, ambassador of the late king of Prussia; and the poet *Angelo Mazza* of Parma.

During his [illegible] Modena, Spallanzani published in [illegible] *Microscopiche concernenti il* [illegible]. He therein established [illegible] called, but not generally [illegible] *microscopic animalcula*, by the most ingenious, and at the same time solid, experiments. He sent this work to Bonnet, who formed his opinion of the author accordingly, and who lived to see the accomplishment of the prophecy he drew from it. From that moment the most intimate acquaintance was formed between them, and it lasted during their lives, of which it constituted the chief happiness. In the same year Spallanzani published a dissertation truly original; *De Lapidibus ab Aqua resilientibus*. In that work he proves, by satisfactory experiments, contrary to the commonly received opinion, that the ducks and drakes (as they are called) are not produced by the elasticity of the water, but by the natural effect of the change of direction which the stone experiences in its movement, after the water has been struck by it, and that it has been carried over the bend or hollow of the cup formed by the concussion.

In 1768 he prepared the philosophers for the surprising discoveries he was about to offer them throughout his life, in publishing his *Prodromo di un Opera da Imprimersi sopra le Riproduzioni Animali*. He therein lays down the plan of a work which he was anxious to get up on this important subject; but this simple prospectus contains more real knowledge than all the books which had appeared, because it taught the method that ought to be followed in this dark research, and contained many unexpected facts; such as the pre-existence of tadpoles at the fecundation, in many species of toads and frogs; the reproduction of the head cut off from snails, which he had already communicated to Bonnet in 1766, and which was disputed for some time, in spite of the repeated confirmation of this phenomenon by Herissant and Lavoisier. He demonstrated it again afterwards in the *Memorie della Societa Italiana*; as also the renewal of the tail, the limbs, and even the jaws, taken from the aquatic salamander. These facts continue to astonish even at this day, when they are thought of, notwithstanding every one has had the opportunity of familiarising himself with them: and we hardly know which we ought most to admire, the expertness of Spallanzani in affording such decisive proofs, or his boldness in searching after them, and seizing them. We have to regret, that the project of his great undertaking is not realized; but various circumstances prevented him from giving way to the solicitations of his friends for its accomplishment. Perhaps he despaired of throwing upon every part of it all the light which at first he thought he might be able; and found it prudent to mature his ideas by new meditations: this may probably have been as powerful a cause as that other calls and occupations, perpetually accumulating, should not have allowed him to pursue it as he had intended. He has always laid Nature open to full view; and the thinnest veil darkened her till he succeeded in removing it altogether.

The physiology of Haller that Spallanzani studied fixed his attention upon the circulation of the blood, in which he discovered several remarkable phenomena. He published, in 1768, a small tract: *Dell' Azione del Cuore ne' Vasi Sanguigni nuovi Osservazioni*, and he reprinted it in 1773, with three new dissertations, *De' Fenomeni della Circolazione osservata nel' Giro universali de' Vasi; De' Fenomeni della Circolazione Languente; De' Moti del Sangue, independente del Azione del Cuore e del Pulsare delle Arterie*. This work, but little known, contains a series of observations and experiments, of the most ingenious and delicate nature, upon a subject of which the surface only is known. It merits the attention of those who are interested in the progress of physiology.

When the university of Padua was re-established upon a larger scale, the Empress Maria Theresa directed the Count de Firmian to invite him to fill a chair, as professor of natural history; his great reputation rendered him eligible for this distinction, solicited by many celebrated men, and he merited it by his success, and by the crowd of students who thronged to his lessons. Only great men make excellent masters, because their ideas are the most perspicuous, the most extensive, and best connected.

Spallanzani united a vast extent of knowledge to a fine genius; a method simple, but rigorous in its nature; and he connected what he knew to principles firmly established. His ardent love of truth made him discuss, with the utmost care, the theories which prevailed; to sound their solidity, and discover their weak sides. The great art which he had acquired, of interpreting Nature by herself, diffused such a light over his lessons, as made every thing perspicuous that was capable of affording instruction. An eloquence at once plain and lively animated his discourse; the purity and elegance of his style charmed all who heard it: in short, it was known that he always occupied himself about

the

the means of rendering his lessons useful, which he prepared a year beforehand. They became always new and engaging, by his new observations, and by the enlarged views that his meditations presented to him. The learned persons who attended his lectures were pleased to become his scholars, in order to know better what they already knew, and to learn that which otherwise they would perhaps never have known.

In arriving at the university, Spallanzani took the *Contemplation de la Nature* of Bonnet for the text of his lessons: he filled up the vacancies in it, he unfolded the ideas, and confirmed the theories by his experiments. He believed, with reason, that the book which inspired him with the love of natural history by reading it, was the most proper to give birth to it in the minds of his disciples.

He translated it into Italian, and enriched it with notes; he added a preface to it, wherein he pointed out the subjects of the vegetable and animal economy, which in an especial manner deserved the attention of his pupils; and sometimes pointing out to them the means of succeeding in their researches. It was thus he at first devoted himself to the pleasing employment of instructor of his countrymen, and that he became the model of those who were desirous of instructing usefully. He published the first volume of his translation in 1769, and the second in 1770.

The connection of Spallanzani with Bonnet had an influence upon his genius, which bent to the severe method of the philosopher of Geneva. He prided himself in being his pupil, and he unceasingly meditated upon his admirable writings; and thus it was that he became desirous of seeking in Nature for the proofs of Bonnet's opinion upon the generation of organized bodies, and that this charming subject fixed his attention for a long time.

He published, in 1776, the two first volumes of his *Opuscoli di Fisica Animale e Vegetabile*: they are the explanation of a part of the microscopic observations which had already appeared.

If the art to observe be the most difficult, it is nevertheless the most necessary of all the arts; but it supposes every quality, every talent: and further, though each believes himself more or less consummate therein, yet it is obvious, that only great men have exercised it in a distinguished manner. Genius alone fixes the objects worthy of regard; that alone directs the senses to the obscurities which it is necessary to dissipate; it watches over them to prevent error; it animates them to follow by the scent, as it were, that which they have but a distant view of: it takes off the veil which covers what we are looking after; it supports the patience which waits the moment for gratifying the sight in the midst of obstacles multiplying one upon another: in short, it is genius that concentrates the attention upon an object, which communicates that energy to him for imagining, that sagacity for discovering, that promptness for perceiving, without which we see only one side of truth, when we do not happen to let it escape altogether. But this is not all; for after Nature has been read with precision, it is necessary to interpret her with fidelity; to analyse by the thought the phenomena anatomised by the senses; to consider of the species by observing the individual, and to anticipate the general propositions by considering the unconnected facts. Here prudence and circumspection will not always secure us against error, if an ardent love for the truth does not allay observations and their consequences in its crucible, and thereby reduce every thing to *scoriæ* which is not truth. Spallanzani.

Such was Spallanzani in all his researches; such we see him in all his writings. Occupied by the great phenomenon of generation, he examined the opinion of Needham to demonstrate its want of foundation. The latter, not satisfied with the microscopic observations of Spallanzani, which weakened the imagined vegetative force to put the matter in motion, challenged the professor of Reggio to a reperusal of what he had written; but he proved to the other, that we in common practice always see that which has been *well observed*, but that we never again see that which we have been contented with *imagining we saw*.

Spallanzani has received much praise for the politeness with which he carried on this controversy, and for the severe logic with which he demonstrates to Needham the causes of his error; and proves, that the animalculæ of infusions are produced by germs; that there are some of them which defy, like certain eggs and seeds, the most excessive cold, as well as the heat of boiling water. On this occasion, he treats on the influence of cold upon animals, and proves that the lethargic numbness of some, during winter, does not depend upon the impression the blood may receive from it; since a frog, deprived of his blood, becomes lethargic when he is reduced to the same cold state by an immersion in ice, and swims as before when restored to warmth. In the same manner he shews that odours, various liquors, the [illegible] act upon animalculæ as upon other animals; that they are [illegible] viviparous, and hermaphrodite. Thus [illegible] over these distant regions of Nature with [illegible] we are always meeting with new facts, profound remarks, precious details, and some curious anecdotes; in short, an universal history of these beings which are the most numerous of the globe, although their existence is scarcely suspected, and whose organization is in many respects different from that of known animals.

The second volume of this work is a new voyage into the most unknown parts; a sublime pencil had already painted it, but the picture was not done after Nature. Spallanzani here gives a history of the spermatic animalcule, which the eloquent historian above alluded to always confounds with the animalculæ of infusions. We cannot but admire the modest diffidence of this new demonstrator, struggling against his own opinion and the authority of Buffon; and he appears to admit, with repugnance, the results of his multiplied, and in a thousand ways varied, observations, which expose the feebleness of the system of organic moleculæ.

Spallanzani afterwards describes the volvox and the slow-moving animalculæ (*rotifère* and *tardigrade*), those colossuses of the microscopic world, so singular by their figure and organization, but more singular still by their faculty of resuming life, after a total suspence of all the apparent acts of it during many years.

We will not here speak of the experiments of Spallanzani on the death of animals in close vessels, because he took up the subject again, and enlarged and exemplified it by the new lights of chemistry; but this collection

lection he concludes with another on the history of vegetable mould growing on the surface of liquors and moist substances, the seeds of which he shews to float in the air; and he remarks, that these microscopic champignons or mushrooms distinguish themselves from other plants by their tendency to grow in all directions, without conforming to the almost universal law of perpendicularity of stalk to the ground.

Spallanzani was placed at the head of the university's cabinet of natural history, but he was little more than titular depositary of a treasure which no longer existed. He laid the foundations, however, for its renewal, and by his care it is become one of the most precious and useful. He enriched it through his repeated travels by land and sea, in Europe, in Asia, across the Apennines, the Alps, the Krapacks, at the bottom of mines, on the top of volcanoes, at the mouth of craters: supported by his ardent passion in the midst of perils, he preserved the *sang-froid* of the philosopher to contemplate these wonders, and the piercing eye of an observer to study them. It is thus that he always distinguished the proper objects for improving science by favouring instruction; it is thus that he filled this depositary with treasures, that all the gold in the world could not have obtained, because gold never supplies the genius and the discernment of the enlightened naturalist.

In 1779 Spallanzani ran over Switzerland and the Grisons; he then went to Geneva, where he spent a month with his friends, who admired him the more in his conversations after having admired him in his writings. He then returned to Pavia, and published, in 1780, two new volumes of his *Dissertazioni di Fisica Animale e Vegetabile*. He therein reveals the secrets of [illegible] obscure phenomena, concerning the [illegible] economy.

[illegible] upon *digestion* [illegible] to study this dark operation, he repeated [illegible] experiments upon the gallinaceous [illegible] the trituration, which [illegible] could not, however, [illegible] that the gizzard of these birds [illegible] of fruit to pieces, as if done [illegible] sharp-pointed instruments, [illegible] powder so formed; that it was [illegible] should undergo a new operation in the stomach before it could become fit chyle for affording the elements of the blood and other humours. He established the point, that the digestion was performed in the stomach of numerous animals by the powerful action of a juice which dissolves the aliments; and to render his demonstration the more convincing, he had the courage to make several experiments on himself which might have proved fatal, and had the address to complete his proofs by artificial digestions made in glasses upon the table, by mixing the chewed aliments with the gastric juice of animals, which he knew how to extract from their stomachs. But this book, so original by the multitude of experiments and curious observations which it contains, is still more worthy of attention by the philosophic spirit which detected it.

This subject is one of the most difficult in physiology: the observer is always compelled to act and to look with darkness around him; he is obliged to manage the animal with care, to avoid the derangement of his operations; and when he has laboriously completed his experiments, it is necessary that he should well distinguish the consequences, sometimes erroneous, which may be drawn from those of observation, which never deceive when they are immediate. Spallanzani, in this work, is truly a fine spectacle; scrupulously analysing the facts in order to discover their causes with certainty; inventing happy resources for surmounting the obstacles which renew themselves; comparing Nature with his experiments, to judge of them; catching hold in his observations of every thing that is essential in them; measuring their solidity by the augmentation or diminution of supposed causes; drawing the best-founded conclusions, and rejecting the most plausible hypotheses; modestly exposing the errors of those who have gone before him, and employing analogy with that wise circumspection which inspires confidence in an instrument at once so dangerous and so useful. But let it be known, Spallanzani had a capacity in particular for discovering the truth, while the greater part of observators scarcely ever attain it; and then, after having described around them a circuitous trace, he runs upon it by a straight line, and possesses himself of it so as that it cannot escape him.

This work put John Hunter out of humour; and he published, in 1785, *Some Observations upon Digestion*, wherein he threw out some bitter sarcasms against Spallanzani; who took ample revenge by publishing this work in Italian, and addressing to *Caldani*, in 1788, *Una Lettera Apologetica in Risposta alle Osservazione del Signor Giovanni Hunter*. He exposes, with moderation, but with an irresistible logic, the oversights of the English physiologist, and points out his errors in a manner which left him no hope of a reply.

The second volume treats of the generation of animals and plants. Spallanzani proves, by experiments as satisfactory as they are surprising, the pre-existence of germs to fecundation; he shews the existence of tadpoles in the females of five different species of frogs, in toads, and in salamanders, before their fecundation: he recounts the success of some artificial fecundations upon the tadpoles of those five species, and even upon a quadruped. He in the same manner shews the seed in the flowers, before the emission of their farina; and by a subtle anatomy of which one can hardly form an idea, he exhibits to the eye in the flower of the *spartium junceum*, the filiqua, its seeds, with their lobes, and the embryo plant; he pursues them in their expansion before and after fecundation, and leaves not a doubt but that the seeds and the pericarpia existed long before the blossoming of the buds, and consequently a long time before they could have been fecundated. He has repeated these observations upon various species of plants with the same results; in short, he has raised the individuals of plants with female flowers which have borne fecundated seeds, although they were out of the reach even of suspicion of a communication with the farina of the male flowers. Such is the series of surprising phenomena Spallanzani adds to the history of Nature.

According to custom, he availed himself of the academical vacation of 1781, to make a journey, the object of which was to add to the cabinet of Pavia. He set out in the month of July for Marseilles, where he commenced a new history of the sea, which had presented him with a crowd of novel and curious facts upon

Spallanzani.

on numerous genera of the inhabitants of the ocean. He went likewise to Finale, to Genoa, to Massa, and to Carrara, to observe the quarries of marble so famous with the statuaries; he returned to Spezzia, and thence brought to Pavia an immense harvest of fishes, crustaceous and testaceous, which he deposited in that cabinet of which his voyages and travels had rendered him so worthy to be the guardian. He visited, in the same view, and with the same success, the coasts of Istria in 1782; the Apennine Mountains in 1783, where he noticed the terrible hurricanes, and the surprising vapours which rendered that year so famous in meteorology. The cabinet of Pavia thus every year saw its riches increase; and in the same proportion it became the object of strangers admiration; but every one admired still more the immense labour of Spallanzani, who had collected every part of it.

The Emperor Joseph knew this when he came into Lombardy: he desired to have a conversation with Spallanzani; and his majesty expressed his approbation by presenting him with his medal in gold.

The university of Padua offered to Spallanzani, in 1785, the chair of natural history, which the death of Anthony Vallisneri had left vacant, promising him more considerable advantages than those which he enjoyed at Pavia; but the archduke doubled his pension, and allowed him to accompany to Constantinople the Chevalier Zuliani, who had just been nominated ambassador from the republic of Venice.

He left this city the 21st of August; and during his voyage made several observations upon the marine productions he met with in those climates, as well as upon the meteorological events of every day, among which he had the advantage of beholding a species of water-spout. He touched at several islands in the Archipelago, which he examined, and went ashore at Troy to visit the places sung by the poet whom he preferred to all others; and in treading upon that ground so anciently famous, he made some geological observations truly original. One may judge before hand of the interest we shall feel in reading the Voyage of Spallanzani, by some memoirs which have appeared in the *Memorie della Societa Italiana* upon the water-spouts at sea, the stroke of the torpedo, divers marine productions, and the island of Cytherea, where he discovered a mountain composed of various species of fossils. Spallanzani arrived at Constantinople the 11th of October, and remained there eleven months: he must have been greatly out of his element in that country of ignorance and superstition, if he had not had Nature to study, and Zuliani to hear him. The physical and moral phenomena of this country, quite new to him, fixed his attention; he strayed over the borders of the two seas, and climbed up the neighbouring hills; he visited the island of Chalki, where he made known to the Turks a mine of copper, the existence of which they never so much as suspected. He went to the Principi island, a few miles distant from Constantinople, where he discovered an iron mine equally unthought of by the Turks. He returned to Europe loaded with spoils from the East, composed of the creatures of the three kingdoms, peculiar to those regions: after having been useful to the Orientals, who were incapable of appreciating his merit, or rather of imagining he could have any, he set out on his return for Italy the 16th of August, 1786.

A voyage by sea was in every respect the most safe and the most commodious; but Spallanzani considered the dangers and the inconveniences of the road as nothing when employed in any beneficial pursuit; he braved all the perils of those desert regions, where there is no police, no security. When he arrived at Bucharest, he was retained there during nine days by the celebrated and unhappy Mauroceni, hospodar of Wallachia. This prince, the friend of science, received him with distinction, presented him with many of the rarities of his country, furnished him with horses for travelling, and also gave him an escort of thirty troopers throughout the whole extent of his dominions. Spallanzani passed by Hermanstadt in Transylvania, and arrived at Vienna the 7th of December, after having viewed the numerous mines of Transylvania, of Hungary, and of Germany, which lay in the neighbourhood of his route. Spallanzani remained five days in this capital of Austria; he had two very long audiences with the Emperor Joseph II.; was well received by the highest nobility in that metropolis, and visited by the men of letters. At length arrived at Pavia; the students came to meet him out of the gates of the city, and accompanied him home, manifesting their joy all the way by repeated shouts. Their great desire to hear him, drew him almost immediately to the auditory, where they forced him to ascend the chair from which he had been accustomed to deliver his lectures to them. Spallanzani, affected by this scene, testified with eloquence his gratitude and [illegible] cries of joy, clapping of [illegible] force, and he was obliged [illegible] allow him to take in [illegible] more necessary than [illegible] year above 500 students.

Spallanzani had acquired glory enough to merit the attacks of envy; but his discoveries were too new, too original, too solid to be disputed; envy itself was therefore forced to admire him; but that unworthy passion, being [illegible] by the increasing reputation of that great man, watched the moment to prove that it had not forgotten him. Envy and malignity then called in question his uprightness in the administration of the cabinet of Pavia; the whole of which was the fruit of his own labours; but the blow aimed at —— only made it shine with new lustre. The integrity of Spallanzani appeared even more pure after the juridical examination of the tribunals. But let us stop here; Spallanzani had the fortitude to forget this event which had torn his heart to pieces; the greater part of his enemies acknowledged their mistake, abjured their hatred, and did not despair of regaining his friendship.

The cabinet of Pavia was always the object of Spallanzani's thoughts; amidst the numerous rarities which he had placed there, he only saw those that were wanting. Struck with its deficiency in volcanic matters, which had neither series nor order, and consequently excited little interest, being a mute article with respect to instruction (although Italy was the theatre where the fires of volcanoes had for so many ages exercised their desolating powers), he took the resolution, with which his talents, his courage, and his zeal, inspired

him

Spallanzani.

him. He was desirous to instruct his pupils, his nation, himself, concerning the phenomena so striking, and yet so little known, and to collect the documents of their history in the places where they have always been the terror of those who surrounded them, and where they have been uselessly the subject of the observations of the philosopher. He therefore prepared himself for this great enterprise by deep studies. He set out for Naples, in the summer of 1788, and ascended mount Vesuvius; he looked attentively into its crater, examined and made notes in his books, and embarked for the Lipari islands. He dissected, as it were, the uninhabited volcanoes, with the exactness of a naturalist anatomising a butterfly, and the intrepidity of a warrior defying the most imminent dangers. It was then that he had the boldness to walk over that sulphurous crust, cleft with chinks, trembling, smoking, burning, and sometimes treacherously covering the hearth of the volcano. He passed into Sicily, where he climbed up to Etna, and coasted its immense crater. His curiosity not being exhausted, he would collect around him, and have in his mind, all the singular phenomena that Sicily contained; he examined the stones and the mountains, and discovered many new marine animals; he approached Scylla and Charybdis, and in a boat crossed the frothy billows of those deadly rocks, celebrated for so many shipwrecks, and so often sung by the poets; but in the very midst of their frightful waves, he discovered the cause of their fury (See SCYLLA, *Suppl.*) It was thus that, at the age of 60, he picked up those numberless anecdotes which fill his voyages in the two Sicilies; and that he compared the description which Homer, Pindar, Virgil, Diodorus Siculus, and Strabo, have given of these ever famous places, with that which he made himself. In this manner he showed the connection of ancient literature with natural history.

We find in the voyages of Spallanzani a new volcanology. He therein teaches the way to measure the intensity of the fire of volcanoes, to [illegible] at the causes, to touch almost, in the analysis which he makes of the lava, that particular gas which, resembling a powerful lever, [illegible] from the bowels of the earth and raises up to the top of Etna, those torrents of stone in fusion which it disgorges; to foresee the nature of those pumice stones, which he has since explained in his artificial pumice-stones. He concludes this charming work with some interesting inquiries into the nature of swallows, their mild dispositions, rapid flight; suggesting that an advantage might be drawn from them in the way of aerial post; their migrations determined by the temperature of the air, and the birth of insects it occasions; in short, he discusses the famous problem of their remaining benumbed during winter; and proves, that artificial cold, much greater than that ever naturally felt in our climates, does not render these birds lethargic. He next speaks of a species of owl, hitherto very ill described; and, lastly, of eels and their generation, which is a problem still in some measure to be solved; but he carries it on by his inquiries to that step which alone remains to be made for obtaining a complete solution; or to get over it easily by a small number of observations in those times and places pointed out, but which the academical occupations of Spallanzani forced him to give up to others.

Spallanzani followed the progress of the French chemistry with much satisfaction, nor was he long before he adopted it; it was calculated for a just conception like his, delighting to give an account of every phenomenon he observed. The solidity of principles in this new doctrine, the precision in its way of proceeding, the elegance of its interpretation, the generality of its consequences, presently replaced in his mind the hesitations and the obscurities of the ancient chemistry; and his heart anticipated with pleasure the triumphs that it was about to obtain.

In 1791, Spallanzani published a letter addressed to Professor Fortis, upon the Pennet Hydroscope. He there relates the experiments which he had directed to be made for ascertaining the degree of confidence which might be allowed to the singular talents of this man; but he ingenuously confesses, that he is not decided upon the reality of the phenomenon.

Spallanzani has often discovered that which mi[illegible] have been deemed impossible. In 1795 he made [illegible] covery of this nature, which he published in hi[illegible] *sopra il sospetto d'un nuovo senso nei Pipistrelli.* W[illegible] in learn that the bats, if blinded, act in every [illegible] with the same precision as those which have th[illegible], that they in the same manner avoid the most t[illegible] stacles, and that they know where to fix thems[illegible] ceasing their flight. These extraordinary experim[illegible] were confirmed by several natural philosophers, an[illegible] gave occasion to suspect a new sense in these birds, because Spallanzani thought he had evinced by the way of exclusion, that the other senses could not supply the deficiency of that sight which he had deprived them of; but the anatomical details of Professor Jurine, upon the organ of hearing in this singular bird, made him incline afterwards towards the idea, that the sense of hearing might in this case supply that of sight, as in all those where the bats are in the dark.

Spallanzani concluded his literary carreer for the public, by a letter addressed to the celebrated Giobert; *Sopra la piante chiuse ne' vasi dentro l'aqua e l'aria, esposte a l' immediata lume solare e a l'ombra.* It is a misfortune for this part of the science, that his death has deprived us of the discoveries he was about to make in it.

These numerous works, printed and applauded, did not however contain all the series of Spallanzani's labours. He had been occupied a considerable time upon the phenomena of respiration; their resemblances and differences in a great number of species of animals; and he was busily employed in reducing to order his researches upon this subject, which will astonish by the multitude of unforeseen and unexpected facts. He has left a precious collection of experiments and new observations upon animal reproductions, upon sponges, the nature of which he determines, and upon a thousand interesting phenomena which he knew how to draw out of obscurity. He had almost finished his voyage to Constantinople, and had amassed considerable materials for a History of the Sea, when an end was put to his life and his labours.

On the 4th of February 1799, he was seized with a retention of urine, the same night was unquiet, and in the morning he lost all powers of reason, which he never recovered but during very short intervals. His intimate friends, Tourdes, a French physician, and the celebrated Professor Scarpa, did every thing which could

could be expected from genius, experience, and friendship, to save him; but he died the 17th, after having edified those around him by his piety. This lamentable event overwhelmed all his family in sorrow, occasioned the tears to flow from all his friends, filled his disciples with a deep affliction, and excited the regret of a nation proud of having given him birth.

The reader cannot but have perceived in this sketch the strain of panegyric, rather than the calm narrative of impartial biography. It is, in fact, an abridged translation of an *eloge* by a *citizen* philosopher of Geneva, who has adopted the calendar, and probably the principles of republican France. Some abatement therefore will naturally be made by every Briton of the praises bestowed upon the piety of Spallanzani; but after proper allowance of this kind, truth will proclaim him a very great man. Accordingly, France, Germany, England, all were eager to avail themselves of his works by means of translations. He was admitted into the academies and learned societies of London, Stockholm, Gottingen, Holland, Lyons, Bologna, Turin, Padua, Mantua, and Geneva. He was a correspondent of the academy of sciences of Paris and of Montpelier: and received from the great Frederic himself the diploma of member of the academy of Berlin.

SPECIES, in algebra, are the letters, symbols, marks, or characters, which represent the quantities in any operation or equation.

SPECIES, in optics, the image painted on the retina by the rays of light reflected from the several points of the surface of an object, received in by the pupil, and collected in their passage through the crystalline, &c.

SPECTACLES (See *Encycl.*) are certainly the most valuable of all optical instruments, though there is not the same science and mechanical ingenuity displayed in the making of them as in the contruction of microscopes and telescopes. A man, especially if accustomed to spend his time among books, would be much to be pitied, when his sight begins to fail, could he not, in a great measure, restore it by the aid of spectacles; but there are some men whose sight cannot be aided by the use either of convex or concave glasses. The following method adopted by one of those to aid his sight is certainly worthy of notice:

When about sixty years of age, this man had almost entirely lost his sight, seeing nothing but a kind of thick mist, with little black specks which appeared to float in the air. He knew not any of his friends, he could not even distinguish a man from a woman, nor could he walk in the streets without being led. Glasses were of no use to him; the best print, seen through the best spectacles, seemed to him like a daubed paper. Wearied with this melancholy state, he thought of the following expedient.

He procured some spectacles with very large rings; and, taking out the glasses, substituted in each circle a conic tube of black Spanish copper. Looking through the large end of the cone he could read the smallest print placed at its other extremity. These tubes were of different lengths, and the openings at the end were also of different sizes; the smaller the aperture the better could he distinguish the smallest letters; the larger the aperture the more words or lines it commanded; and consequently the less occasion was there for moving the head and the hand in reading. Sometimes he used one eye, sometimes the other, alternately relieving each, for the rays of the two eyes could not unite upon the same object when thus separated by two opaque tubes. The thinner these tubes, the less troublesome are they. They must be totally blackened within so as to prevent all shining, and they should be made to lengthen or contract, and enlarge or reduce the aperture at pleasure.

When he placed convex glasses in these tubes, the letters indeed appeared larger, but not so clear and distinct as through the empty tube: he also found the tubes more convenient when not fixed in the spectacle rings; for when they hung loosely they could be raised or lowered with the hand, and one or both might be used as occasion required. It is almost needless to add, that the material of the tubes is of no importance, and that they may be made of iron or tin as well as of copper, provided the insides of them be sufficiently blackened. See *La Nouvelle Bigarure* for February 1754, or *Monthly Magazine* for April 1799.

SPECTRE OF THE BROKEN, a curious phenomenon observed on the summit of the *Broken*, one of the Harz mountains in Hanover. We have the following account of it by M. Haue. "After having been here (says he) for the thirtieth time, and having procured information respecting the abovementioned atmospheric phenomenon, I was at length, on the 23d of May 1797, so fortunate as to have the pleasure of seeing it; and perhaps my description may afford satisfaction to others who visit the Broken through curiosity. The sun rose about four o'clock, and, the atmosphere being quite serene towards the east, his rays could pass without any obstruction over the Heinrichshöhe. In the south-west, however, towards Achtermannshöhe, a brisk west wind carried before it thin transparent vapours, which were not yet condensed into thick heavy clouds.

"About a quarter past four I went towards the inn, and looked round to see whether the atmosphere would permit me to have a free prospect to the south-west; when I observed, at a very great distance towards Achtermannshöhe, a human figure of a monstrous size. A violent gust of wind having almost carried away my hat, I clapped my hand to it by moving my arm towards my head, and the colossal figure did the same.

"The pleasure which I felt on this discovery can hardly be described; for I had already walked many a weary step in the hopes of seeing this shadowy image, without being able to gratify my curiosity. I immediately made another movement by bending my body, and the colossal figure before me repeated it. I was desirous of doing the same thing once more—but my colossus had vanished. I remained in the same position, waiting to see whether it would return; and in a few minutes it again made its appearance on the Achtermannshöhe. I paid my respects to it a second time, and it did the same to me. I then called the landlord of the Broken; and having both taken the same position which I had taken alone, we looked towards the Achtermannshöhe, but saw nothing. We had not, however, stood long, when two such colossal figures were formed over the above eminence, which repeated our compliments by bending their bodies as we did; after which they vanished. We retained our position; kept our eyes fixed on the same spot, and in a little the two figures again stood before us, and were joined by a third. Every movement that we made by bending our bodies

bodies these figures imitated—but with this difference, that the phenomenon was sometimes weak and faint, sometimes strong and well defined. Having thus had an opportunity of discovering the whole secret of this phenomenon, I can give the following information to such of my readers as may be desirous of seeing it themselves. When the rising sun, and according to analogy the case will be the same at the setting sun, throws his rays over the Broken upon the body of a man standing opposite to fine light clouds floating around or hovering past him, he needs only fix his eyes stedfastly upon them, and, in all probability, he will see the singular spectacle of his own shadow extending to the length of five or six hundred feet, at the distance of about two miles before him."

If our memory does not deceive us, there is in one of the volumes of the *Manchester Transactions* an account of a similar phenomenon observed by Dr Ferrier, on a hill somewhere in England.

SPECULUM for reflecting telescopes. Under this title (*Encycl.*) we have given the composition of the mixt metal of which it has been found by experience that the best speculums are made; we have likewise given, under the same title, some directions for casting speculums; but owing to a circumstance in which the public can take no interest, we neglected to give directions for grinding and polishing them, and omitted some other circumstances, which, though not so important as these, are certainly worthy of notice. These omissions it is the object of this article to supply.

When the metal is taken out of the flasks (See n° 3. of the article referred to), which it should be as soon as it has become solid, and while it is yet red-hot, care must be taken to keep the face downwards to prevent it from sinking. Holding it in that position by the git, force out the sand from the hole in the middle of the mirror with a piece of wood or iron, and place the speculum in an iron pot with a large quantity of hot ashes or small coals, so as to bury the speculum in them a sufficient depth. If the sand is not forced out of the hole in the manner above directed, the metal, by sinking as it cools, will embrace the sand in the middle of the speculum so tight, as to cause it to crack before it becomes entirely cold. And if the metal is not taken out of the sand, and put in a pot with hot ashes or coals to anneal, the moisture from the sand will always break the metal. Let the speculum remain in the ashes till the whole becomes quite cold. The git may be easily taken off by marking it round with a common fine half round file, and giving it then a gentle blow. The metal is then to be rough ground and figured.

It may be proper, however, before we proceed to describe that process, to give an account of another composition for the speculum of a reflecting telescope, which has been employed with great success by Rochon director of the marine observatory at Brest. Of this composition the principal ingredient is platinum; which, in grains, must be purified in a strong fire by means of nitre and the salt of glass, or that flux which in the English glass-houses is called by the workmen *sandifer*. To the platinum, when purified, add the eighth part of the metal employed in the composition of common specula; for tin without red copper would not produce a good effect. This mixture is then to be exposed to the most violent heat, which must be still excited by the oxygen gas that disengages itself from nitre when thrown into the fire. One melting would be insufficient: five or six are requisite to bring the mixture to perfection. It is necessary that the metal should be in a state of complete fusion at the moment when it is poured into the mould. By this process I have been enabled (says our author) to construct a telescope with platinum, which magnifies the diameters of objects five hundred times, with a degree of clearness and distinctness requisite for the nicest observations. The large speculum of platinum weighs fourteen pounds: it is eight inches in diameter, and its focus is six feet. Though the high price of platinum will, in all probability, for ever prevent it from coming into general use for the speculums of telescopes, we thought it proper to notice this discovery, and shall now proceed to the grinding of the speculum.

For the accomplishing of this object, a very complicated process is recommended in Smith's Optics, and one not much more simpler by Mr Mudge in the 67th volume of the *Philosophical Transactions*; but according to Mr Edwards, whose speculums are confessedly the best, neither of these is necessary. Besides a common grindstone, all the tools that he made use of are a rough grinder, which serves also as a polisher, and a bed of hones. When the speculum was cold, he ground its surface bright on a common grindstone, previously brought to the form of the gage; and then took it to the rough grinder.

This tool is composed of a mixture of lead and tin, or of pewter, and is made of an elliptical form, of such dimensions, that the shortest diameter of the ellipse is equal to the diameter of the mirror or speculum, and the longest diameter is to the shortest in the proportion of ten to nine. This rough grinder may be fixed upon a block of wood, in order to raise it higher from the bench; and as the metal is ground upon it with fine emery, Mr Mudge, with whom, in this particular, Mr Edwards agrees, directs a hole or pit to be made in the middle of it as a lodgement for the emery, and deep grooves to be cut out across its surface with a graver for the same purpose. By means of a handle, fixed on the back of the metal with soft cement, the speculum can be whirled round upon this grinder so rapidly, that a common labourer has been known to give a piece of metal, four inches in diameter, so good a face and figure as to fit it for the hones in the space of two hours. The emery, however fine, will break up the metal very much; but that is remedied by the subsequent processes of honing and polishing.

When the metal is brought to a true figure, it must be taken to a convex tool, formed of some stones from a place called Edgedon in Shropshire, situated between Ludlow and Bishop's Castle. The common blue hones, used by many opticians for this purpose, will scarcely touch the metal of Mr Edwards's speculums; but where they must be employed for want of the others, as little water should be used as possible when the metal is put upon them; because it is found by experience that they cut better when but barely wet, than when drenched with water. The stones, however, from Edgedon are greatly preferable; for they cut the metal more easily, and having a very fine grain, they bring it to a smooth face. These stones are directed by Mr Mudge to be cemented in small pieces upon a thick round piece of

 marble,

Speculum.

marble, or of metal made of tin and lead like the former compoſition, in ſuch a manner, that the lines between the ſtones may run ſtraight from one ſide to the other; ſo that placing the teeth of a very fine ſaw in each of theſe diviſions, they may be cleared from one end to the other of the cement which riſes between the ſtones. As ſoon as the hones are cemented down, this tool muſt be fixed in the lathe, and turned as exactly true to the gage as poſſible. It ſhould be of a circular figure, and but very little larger than the metal intended to be figured upon it. If it be made conſiderably larger, it will grind the metal into a larger ſphere and a bad figure; and if it be made exactly of the ſame ſize, it will work the metal indeed into a figure truly ſpherical, but will be apt to ſhorten its focus, unleſs the metal and tool be worked alternately upwards. On theſe accounts, Mr Edwards recommends it to be made about one twentieth part longer in diameter than the ſpeculum, becauſe he has found that it does not then alter its focus; and he earneſtly diſſuades the uſe of much water on the hone pavement at the time of uſing it, otherwiſe, he ſays, that the metal in different parts of it will be of different degrees of brightneſs.

When the metal is brought to a very fine face and figure by the bed of ſtones, it is ready to receive a poliſh, which is given to it by the elliptical rough grinder covered with pitch. With reſpect to the conſiſtency of this pitch, Mr Mudge and Mr Edwards give very different directions. Whilſt the former ſays that it ſhould be neither too hard nor too ſoft, the latter affirms that the harder the pitch is, the better figure it will give to the metal. Pitch may be eaſily made of a ſufficient hardneſs by adding a proper quantity of roſin; and when it is hardened in this way, it is not ſo brittle as pitch alone, which is hardened by boiling. Mr Edwards adviſes to make the mixture juſt ſo hard as to receive, when cold, an impreſſion from a moderate preſſure of the nail of one's finger. When the elliptical tool is to be covered with this mixture, it muſt be made pretty warm, and in that ſtate have the mixture poured upon it when beginning to cool in the crucible. Our author recommends this coating to be made everywhere of about the thickneſs of half-a-crown; and to give it the proper form, it muſt, when ſomewhat cool, be preſſed upon the face of the mirror, which has firſt been dipped in cold water, or covered over with very fine writing paper. If it be not found to have taken the exact figure from the firſt preſſure, the ſurface of the pitch muſt be gently warmed, and the operation repeated as before. All the ſuperfluous pitch is now to be taken away from the edge of the poliſher with a penknife, and a hole to be made in the middle, accurately round, with a conical piece of wood. This hole ſhould go quite through the tool, and ſhould be made of the ſame ſize, or ſomewhat leſs than the hole in the middle of the ſpeculum. Mr Edwards ſays, that he has always found that ſmall mirrors, though without any hole in the middle, poliſh much better, and take a more correct figure, for the poliſher's having a hole in the middle of it.

The poliſher being thus formed, it muſt be very gently warmed at the fire, and divided into ſeveral ſquares by the edge of a knife. Theſe, by receiving the ſmall portion of metal that works off in poliſhing, will cauſe the figure of the ſpeculum to be more correct than if no ſuch ſquares had been made. Mr Mudge directs the poliſher to be ſtrewed over with very fine *putty*; but Mr Edwards prefers COLCOTHAR of vitriol. (See that article, *Encycl.*) Putty (ſays he) gives metals a white luſtre, or, as workmen call it, a ſilver hue; but good colcothar of vitriol will poliſh with a very fine and high black luſtre, ſo as to give the metal finiſhed with it the complection of poliſhed ſteel. To know if the colcothar of vitriol is good, put ſome of it into your mouth, and if you find it diſſolves away it is good; but if you find it hard, and crunch between your teeth, then it is bad, and not well burned. Good colcothar of vitriol is of a deep red, or of a deep purple colour, and is ſoft and oily when rubbed between the fingers; bad colcothar of vitriol is of a light red colour, and feels harſh and gritty. The colcothar of vitriol ſhould be levigated between two ſurfaces of poliſhed ſteel, and wrought with a little water; when it is worked dry, you may add a little more water, to carry it lower down to what degree you pleaſe. When the colcothar of vitriol has been wrought dry three or four times, it will acquire a black colour, and will be low enough, or ſufficiently fine, to give an exquiſite luſtre. This levigated colcothar of vitriol muſt be put into a ſmall phial, and kept with ſome water upon it. When it is to be uſed, every part of the pitch-poliſher muſt be firſt bruſhed over with a fine camel's hair bruſh, which has been dipped in pure water, and rubbed gently over a piece of dry clean ſoap. The waſhed colcothar of vitriol is then to be put upon the poliſher; and Mr Edwards directs a large quantity of it to be put on at once, ſo as to ſaturate the pitch, and form a fine coating. If a ſecond or third application of this powder be found neceſſary, it muſt be uſed very ſparingly, or the poliſh will be deſtroyed which has been already attained. When the metal is nearly poliſhed, there will always appear ſome black mud upon its ſurface, as well as upon the tool. Part of this muſt be wiped away with ſome very ſoft waſh leather; but if the whole of it be taken away, the poliſhing will not be ſo well completed.

With reſpect to the *parabolic figure* to be given to the mirror, Mr Edwards aſſures us, that a very little experience in theſe matters will enable any one to give it with certainty, by poliſhing the ſpeculum in the common manner, only with croſs ſtrokes in every direction, upon an elliptical tool of the proper dimenſions.

Speculum || Spinning-Machine.

SPINDLE, in geometry, a ſolid body generated by the revolution of ſome curve line about its baſe or double ordinate; in oppoſition to a conoid, which is generated by the rotation of the curve about its axis or abſciſs, perpendicular to its ordinate. The ſpindle is denominated circular, elliptic, hyperbolic, or parabolic, &c. according to the figure of its generating curve.

SPINDLE, in mechanics, ſometimes denotes the axis of a wheel, or roller, &c. and its ends are the pivots.

SPINNING MACHINE. The ancient Greeks were not, like the modern philoſophers, unwilling to acknowledge their obligations to Providence for all the comforts and enjoyments of life, nor felt pride in deriving every thing from their own talents. They were even diſpoſed to think that thoſe very talents were inſpired. Their firſt inſtructors, the poets, gave to Apollo the honour of that power of invention and imagination by which they inſtructed and charmed their admiring hearers. The propheteſs dictated her oracles, the

Spinning-Machine. the poet sung his enraptured strain only when inspired. The happy thought of twining a thread, and working it into a blanket, when viewed by that ingenious and acutely sensible people in all its importance, as the protector of the human race from the severity of the weather, seemed a present from heaven, as the inspiration of a divinity; and the distaff and the loom were Minerva's first title to a seat among the great gods on Olympus.

We are much inclined to be of the same opinion. When we observe, that in all the countries which have been discovered by the navigators of the three last centuries, the distaff and spindle, and the needle, have been found, we own ourselves much disposed to think that they are the results of instinct. Our instincts are not all simple and blind, like that which directs the new-born animal to the breast of its mother without knowing why. We have instincts of intellect as well as of appetite; and the logic of common conversation is an example of many such. We doubt not but that the noble-minded inhabitants of Pelew would have worshipped as a divinity an English maiden with her spinning wheel and fly. Surely he who should carry them this homely but ingenious machine, and a potter's wheel, would do them more service than if he taught them all the science of a Newton, with all the philosophy of the 18th century into the bargain. We do not know, except perhaps the steam engine, any mechanical invention that has made such amazing addition to the activity and industry and opulence of this highly favoured island, as the invention of Mr Arkwright for spinning by water, where dead matter is made to perform all the nicest finger can do when directed by the never-ceasing attention of the intelligent eye. Minerva has the undisputed honours of the distaff and spindle. We know not to what benefactor we owe the fly-wheel. Mr Arkwright has the honour of combining them both, and inspiring them with his own spirit; for we may truly say of the contrivance which pervades the wonderful machinery of a cotton mill,

Totosque infusa per artus
Mens agitat molem et magno se corpore miscet.

To give an intelligible and accurate description of a cotton mill would be abundant employment for a volume. Our limits admit of nothing like this; but as we are certain that many of our readers have viewed a cotton mill with wonder, but not with intelligence, nor with leisure to trace the steps by which the wool from the bag ultimately assumes the form of a very fine thread. Bewildered by such a complication of machinery, all in rapid motion, very few, we imagine, are able to recollect with distinctness and intelligence the essential part of the process by which the form of the cotton is so wonderfully changed. Such readers will not think a page or two misemployed, if they are thereby able to understand this particular, to which all the rest of the process is subservient.

We pass over the operation of carding, by which all the clots and inequalities of the cotton wool are removed, and the whole is reduced to an uniform thin fleece, about 20 inches broad. This is gradually detached from the finishing card, and, if allowed to hang down from it, would pile up on the floor as long as the mill continues to work; but it is guided off from the card, very tenderly, in a horizontal direction, by laying its detached end over a roller, which is slowly turned round by the machine. Another roller lies above the fleece, pressing it down by its weight. By this pressure, a gentle hold is taken of the fleece, and therefore the slow motion of the rollers draws it gently from the card at the same rate as it is disengaged by the comb; but between the card and the rollers a set of smooth pins are placed in two rows, leading from the card to the rollers, and gradually approaching each other as we approach the rollers. By these pins the broad fleece is hemmed in on both sides, and gradually contracted into a thick roll; and in this state passes between the rollers, and is compressed into a pretty firm flat riband, about two inches broad, which falls off from the rollers, and piles up in deep tinplate cans set below to receive it.

It is upon this stripe or riband of cotton wool that the operation of spinning begins. The general effect of the spinning process is to draw out this massive roll, and to twist it as it is drawn out. But this is not to be done by the fingers, pulling out as many cotton fibres at once as are necessary for composing a thread of the intended fineness, and continuing this manipulation regularly across the whole end of the riband, and thus, as it were, nibbling the whole of it away. The fingers must be directed, for this purpose, by an attentive eye. But in performing this by machinery, the whole riband must be drawn out together, and twisted as it is drawn. This requires great art, and very delicate management. It cannot be done at once; that is, the cotton roll cannot first be stretched or drawn out to the length that is ultimately produced from a tenth of an inch of the roll, and then be twisted. There is not cohesion enough for this purpose; we should only break off a bit of the roll, and could make no farther use of it. The fibres of cotton are very little implicated among each other in the roll, because the operation of carding has laid them almost parallel in the roll; and though compressed a little by its contraction from a fleece of 20 inches to a riband of only 2, and afterwards compressed between the discharging rollers of the carding machine, yet they cohere so slightly, that a few fibres may be drawn out without bringing many others along with them. For these reasons, the whole thickness and breadth of two or three inches of the riband is stretched to a very minute quantity, and then a very slight degree of twist is given it, viz. about three turns in the inch; so that it shall now compose an extremely soft and spungy cylinder, which cannot be called a thread or cord, because it has scarcely any firmness, and is merely rounder and much slenderer than before, being stretched to about thrice its former length. It is now called slab, or roove.

Although it be still extremely tender, and will not carry a weight of two ounces, it is much more cohesive than before, because the twist given to it makes all the longitudinal fibres bind each other together, and compress those which lie athwart; therefore it will require more force to pull a fibre from among the rest, but still not nearly enough to break it. In drawing out a single fibre, others are drawn out along with it; and if we take hold of the whole assemblage, in two places, about an inch or two inches asunder, we shall find that we may draw it to near twice its length without any

risk of its separating in any intermediate part, or becoming much smaller in one part than another. It seems to yield equably over all.

Such is the state of the slab or roove of the first formation. It is usually called the *preparation;* and the operation of spinning is considered as not yet begun. This preparation is the most tedious, and requires more attendance and hand labour than any subsequent part of the process. For the stripes or ribands from which it is made are so light and bulky, that a few yards only can be piled up in the cans set to receive them. A person must therefore attend each thread of slab, to join fresh stripes as they are expended. It is also the most important in the manufacture; for as every inch of the slab meets with precisely the same drawing and the same twisting in the subsequent parts of the process, therefore every inequality and fault in the slab (indeed in the fleece as it quits the finishing card) will continue through the whole manufacture. The spinning of cotton yarn now divides into two branches. The first, performed by what are called *jennies*, perfectly resembles the ancient spinning with the distaff and spindle; the other, called *spinning of twist*, is an imitation of the spinning with the fly-wheel. They differ in the same manner as the spinning with the old wool or cotton-wheel differs from the spinning with the flax-wheel. Mr Arkwright's chief invention, the substitution of machinery for the immediate work of the human finger, is seen only in the manufacture of twist. We shall therefore confine our attention to this.

The rest of the process is little more than a repetition of that gone through in making the first slab or roove. It is formed on bobins. These are set on the back part of the drawing frame; and the end of the slab is brought forwards toward the attending workman. As it comes forward, it is stretched or drawn to about $\frac{4}{5}$ of its former length, or lengthened $\frac{1}{4}$; and is then twisted about twice as much as before, and in this state wound up on another bobin. In some mills two rooves, after having been properly drawn, are brought together through one hole, and twisted into one; but we believe that, in the greater number of mills, this is deferred to the second drawing. It is only after the first drawing that the produce of the operation gets the name of *slab;* before this it is called *preparation*, or *roove*, or by some other name. The slab is still a very feeble, soft, and delicate yarn, and will not carry much more weight than it did before in the form of roove. The perfection of the ultimate thread or yarn depends on this extreme softness; for it is this only which makes it susceptible of an equable stretching; all the fibres yielding and separating alike.

The next operation is the *second drawing*, which no way differs from the first, except in the different proportions of the lengthening, and the proportion between the lengthening and the subsequent twist. On these points we cannot give any very distinct information. It is different in different mills, and with different species of cotton wool, as may be easily imagined. The immediate mechanism or manipulation must be skilfully accommodated to the nature of that friction which the fibres of cotton exert on each other, enabling one of them to pull others along with it. This is greatly aided by the contorted curled form of a cotton fibre, and a considerable degree of elasticity which it possesses. In this respect it greatly resembles woollen fibres, and differs exceedingly from those of flax: and it is for this reason that it is scarcely possible to spin flax in this way: its fibres become lank, and take any shape by the slightest compression, especially when damp in the slightest degree. But besides this, the surface of a cotton fibre has a harshness or roughness, which greatly augments their mutual friction. This is probably the reason why it is so unfit for tents and other dressings for wounds, and is refused by the surgeon even in the meanest hospitals. But this harshness and its elasticity, fit it admirably for the manufacture of yarn. Even the shortness of the fibre is favourable; and the manufacture would hardly be possible if the fibre were thrice as long as it generally is. If it be just so long that in the finished thread a fibre will rather break than come out from among the rest, it is plain that no additional length can make the yarn any stronger with the same degree of compression by twining. A longer fibre will indeed give the same firmness of adherence with a smaller compression. This would be an advantage in any other yarn; but in cotton yarn the compression is already as slight as can be allowed; were it less, it would become woolly and rough by the smallest usage, and is already too much disposed to teazle out. It can hardly be used as sewing thread. Now suppose the fibres much longer; some of them may chance to be stretched along the slab through their whole length. If the slab is pulled in opposite directions, by pinching it at each end of such [illegible] it will not stretch till this fibre be broken [illegible] while it is in its extended [illegible] fibres in a very unequable [illegible] positions, and [illegible] irregularly. [illegible] of flax by similar [illegible] vented (we [illegible]) the working up of any thing but the *shorts* or tow, [illegible] flax in the operation of heckling.

A third, and sometimes even a fourth, drawing is given to the slab formed on the bobins of this second operation. [illegible] still [illegible] of considerable extension, [illegible] smallest [illegible] In one of [illegible] scribed, [illegible] former drawings, [illegible] them. The practice [illegible] plain, that unless great care be taken to preserve the slab extremely soft and [illegible] during the whole process, the subsequent drawing becomes more precarious, and we run a risk of at last making a bad and loose thread instead of a uniform and simple yarn. Such a thread will have very little lateral connection, and will not bear much handling without separating into strands. The perfection of the yarn depends on having the last slab as free of all appearance of strands as possible.

The last operation is the spinning this slab. This hardly differs from the foregoing drawings in any thing but the twist that is given it after the last stretching in its length. This is much greater than any of the preceding, being intended to give the yarn hardness and firmness, so that it will now break rather than stretch any more.

The

The reader, moderately acquainted with mechanics, cannot but perceive that each of the operations now described, by which the roove is changed into the soft flab, and each of these into one slenderer and somewhat firmer, by alternately teazling out and twining the soft cord, is a substitute for a single pull of the finger and thumb of the spinster, which she accommodates precisely to the peculiar condition of the lock of wool which she touches at the moment. She can follow this thro' all its irregularities; and perhaps no two succeeding plucks are alike. But when we cannot give this momentary attention to every minute portion, we must be careful to introduce the roove in a state of perfect uniformity; and then every inch being treated in the same manner, the final result will be equable—the yarn will be uniform.

We are now to describe the mechanism by which all this is effected. But we do not mean to describe a cotton mill; we only mean to describe what comes into immediate contact with the thread; and in so doing, to confine ourselves to what is necessary for making the reader perceive its ability to perform the required task. We see many cases where individuals can apply this knowledge to useful purposes. More than this would, we think, be improper, in a national point of view.

Let ABC represent the section of a roller whose pivot D does not turn in a pivot hole, but in the bottom of a long narrow notch DE, cut in an iron standard: *abc* is the section of another iron roller, whose pivot *d* is in the same notches at each end, while the roller itself lies or rests on the roller ABC below. The surfaces of these rollers are fluted lengthwise [illegible] only the flutings are very small, and [illegible] close together. [illegible] ABC be made to [illegible] in the direction [illegible] the roughness of [illegible] of the upper roller *abc* [illegible] the [illegible] DE [illegible]. If there[illegible] band [illegible] will be pulled in by this [illegible] side at H, [illegible] by the weight of the upper roller, [illegible] down by a lever [illegible] proper places, and is loaded [illegible]. There is nothing to hinder this motion of the riband thus compressed between the rollers; and it will therefore be drawn thro' from the cans. The compressed part at H would hang down, and be piled up on the floor as it is drawn thro'; but it is not permitted to hang down in this manner, but is brought to another pair of sharp fluted iron rollers K and L. Supposing this pair of rollers to be of the same diameter, and to turn round in the same time, and in the same direction with the rollers ABC, *abc*; it is plain that K and L drag in the compressed riband at I, and would deliver it on the other side at M, still more compressed. But the roller K is made (by the wheelwork) to turn round more swiftly than ABC. The difference of velocity at the surface of the rollers is, however, very small, seldom exceeding one part in 12 or 15. But the consequence of this difference is, that the skein of cotton HI will be lengthened in the same proportion; for the upper rollers pressing on the under ones with a considerable force, their sharp flutings take good hold of the cotton between them; and since K and L take up the cotton faster than ABC, and *abc* deliver it out, it must either be forcibly pulled through between the first rollers, or it must be stretched a little by the fibres slipping among each other, or it must break. When the extension is so very moderate as we have just now said, the only effect of it is merely to begin to draw the fibres (which at present are lying in every possible direction) into a more favourable position for the subsequent extensions.

Spinning-Machine.

The fibres being thus drawn together into a more favourable position, the cotton is introduced between a third pair of rollers O, P, constructed in the same way, but so moved by the wheelwork that the surface of O moves nearly or fully twice as fast as the surface of K. The roller P being also well loaded, they take a firm hold of the cotton, and the part between K and O is nearly or fully doubled in its length, and now requires a little twining to make it roundish, and to consolidate it a little.

It is therefore led sloping downwards into a hole or eye in the upper pivot of the first fly, called a *jack*. This turns round an upright axis or spindle; the lower end of which has a pulley on it to give it motion by means of a band or belt, which passes round a drum that is turned by the machinery. This jack is of a very ingenious and complicated construction. It is a substitute for the fly of the common spinning wheel. If made precisely in the form of that fly, the thread, being so very bulky and spongy, and unable to bear close packing on the bobin, would swag out by the whirling of the fly, and would never coil up. The bobin therefore is made to lie horizontally; and this occasions the complication, by the difficulty of giving it a motion round a horizontal axis, in order to coil up the twisted roove. Mr Arkwright has accomplished this in a very ingenious manner; the essential circumstances of which we shall here briefly describe. A is a roller of hard wood, having its surface cut into sharp flutes longitudinally. On the axis, which projects through the side of the general frame, there is a pulley B, connected by a band with another pulley Q, turning with the horizontal axis QR. This axis is made to turn by a contrivance which is different in every different cotton mill. The simplest of all is to place above the pulley C (which is turned by the great band of the machinery, and thus gives motion to the jack), a thin circular disc D, loose upon the axis, so as to turn round on it without obstruction. If this disc exceed the pulley in breadth about [illegible]th of an inch, the broad belt which turns the pulley will also turn it; but as its diameter is greater than that of the pulley, it will turn somewhat slower, and will therefore have a relative motion with respect to the axis QR. This can be employed, in order to give that axis a very slow motion, such as one turn of it for 20 or 30 of the jack. This we leave to the ingenuity of the reader. The bobin B, on which the roove is to be coiled up, lies on this roller, its pivots passing through upright slits in the sides of the general frame. It lies on A, and is moved round by it, in the same manner as the uppermost of a pair of drawing rollers lies on the under one, and receives motion from it. It is evident that the fluted surface of A, by turning, slowly

ſlowly round, and carrying the weight of the bobin, compreſſes a little the cotton that is between them; and its flutings, being ſharp, take a ſlight hold of it, and cauſe it to turn round alſo, and thus coil up the roove, pulling it in through the hole E in the upper pivot (which reſembles the fore pivot or eye of a ſpinning wheel fly) in ſo gentle a manner as to yield whenever the motion of the bobin is too great for the ſpeed with which the cotton ſkein is diſcharged by the rollers O and P.—*N. B.* The axis QR below, alſo gives motion to a guide within the jack, which leads the roove gradually from one end of the bobin to the other, and back again, ſo as to coil it with regularity till the bobin is full. The whole of this internal mechaniſm of the jack is commonly ſhut up in a tin cylinder. This is particularly neceſſary when the whirling motion muſt be rapid, as in the ſecond and third drawings. If open, the jacks would meet with much reſiſtance from the air, which would load the mill with a great deal of uſeleſs work.

The reader is deſired now to return to the beginning of the proceſs, and to conſider it attentively in its different ſtages. We apprehend that the deſcription is ſufficiently perſpicuous to make him perceive the efficacy of the mechaniſm to execute all that is wanted, and prepare a ſlab that is uniform, ſoft, and ſtill very extenſible; in ſhort, fit for undergoing the laſt treatment, by which it is made a fine and firm yarn.

As this part of the proceſs differs from each of the former, merely by the degree of twiſt that is given to the yarn, and as this is given by means of a fly, not materially different from that of the ſpinning wheel for flax, we do not think it at all neceſſary to ſay any thing more about it.

The intelligent reader is ſurely ſenſible that the yarn produced in this way muſt be exceedingly uniform. The uniformity really produced even exceeds all expectation; for even although there be ſome ſmall inequalities in the carded fleece, yet if theſe are not matted clots, which the card could not equaliſe, and only conſiſt of a little more thickneſs of cotton in ſome places than in others, when ſuch a piece of the ſtripe comes to the firſt roller, it will be rather more ſtretched by the ſecond, and again by the bobin, after the firſt very ſlight twining. That this may be done with greater certainty, the weights of the firſt rooving rollers are made very ſmall, ſo that the middle part of the ſkein can be drawn through, while the outer parts remain faſt held.

We are informed that a pound of the fineſt Bourbon cotton has been ſpun into a yarn extending a few yards beyond 119 miles!

Elater SPRING, in phyſics, denotes a natural faculty, or endeavour, of certain bodies to return to their firſt ſtate, after having been violently put out of the ſame by compreſſing, or bending them, or the like. This faculty is uſually called by philoſophers *elaſtic force*, or *elaſticity*.

T. SQUARE, or *Tee Square*, an inſtrument uſed in drawing, ſo called from its reſemblance to the capital letter T.

STAPELIA, a genus of plants belonging to the claſs pentandria, in the Linnæan arrangement, and to the order digynia. The generic characters are the following: The *calyx* is monophyllous, quinquefid, acute, ſmall, and permanent. The *corolla* is monopetalous, flat, large, and divided, deeper than the middle, into five parts, with broad, flat, pointed *laciniæ*. The *nectarium* is ſmall, ſtar-ſhaped, flat, quinquefid, with linear *laciniæ*; and embracing with its ragged points the ſeed-forming parts. Another ſmall ſtar, which is alſo flat and quinquefid, covers the ſeminiferous parts with its entire acute *laciniæ*. The *ſtamina* are five in number; the *filaments* are erect, flat, and broad; and the *antheræ* are linear, on each ſide united to the ſide of the filament. The *piſtillum* has two *germina*, which are oval and flat on the inſide. There are no *ſtyles*; and the *ſtigmata* are obſolete. The *ſeed-veſſel* conſiſts of two oblong, awl-ſhaped, unilocular and univalved follicles. The *ſeeds* are numerous, imbricated, compreſſed, and crowned with a *pappus* or down.

This ſingular tribe of plants is peculiar to the ſandy deſerts of Africa and Arabia. They are extremely ſucculent. From this peculiarity of ſtructure, the power of retaining water to ſupport and nouriſh them, they are enabled to live during the prevalent droughts of thoſe arid regions. On this account the ſtapelia has been compared to the camel; and we are told that, by a very apt ſimilitude, it has been denominated "the *camel* of the vegetable kingdom." We muſt confeſs ourſelves quite at a loſs to ſee the propriety or aptitude of this compariſon. In many parts of the animal and vegetable economy there is doubtleſs a very obvious and ſtriking analogy; but this analogy has been often carried too far; much farther than fair experiment and accurate obſervation will in any degree ſupport. It is perhaps owing to this inaccuracy in obſerving the peculiarity of ſtructure and diverſity of functions, that a reſemblance is ſuppoſed to exiſt, as in the inſtance before us, where in reality there is none. The camel is furniſhed with a bag or fifth ſtomach, [illegible] with which ruminant animals are provided. This fifth ſtomach is deſtined as a reſervoir to contain water; and it is ſufficiently capacious to receive a quantity of that neceſſary fluid, equal to the wants of the animal for many days; and this water, as long as it remains in the fifth ſtomach, is ſaid to be perfectly pure and unchanged. The ſtapelia, and other ſucculent plants, have no ſuch reſervoir. The water is equally, or nearly ſo, diffuſed through the whole plant. Every veſſel and every cell is fully diſtended. But beſides, this water, whether it be received by the roots, or abſorbed from the atmoſphere, has probably undergone a complete change, and become, after it has been a ſhort time within the plant, a fluid poſſeſſed of very different qualities.

The peculiar economy in the ſtapelia, and other ſucculent plants, ſeems to exiſt in the abſorbent and exhalant ſyſtems. The power of abſorption is as much increaſed as the power of the exhalant or perſpiratory veſſels is diminiſhed. In theſe plants, a ſmall quantity of nouriſhment is required. There is no ſolid part to be formed, no large fruit to be produced. They generally have very ſmall leaves, often are entirely naked; ſo that taking the whole plant, a ſmall ſurface only is expoſed to the action of light and heat, and conſequently a much ſmaller proportion of water is decompoſed than in plants which are much branched and furniſhed with leaves.

Two ſpecies of ſtapelia only were known at the beginning of the century. The unfortunate Forſkål, the companion

companion of Niebhur, who was sent out by the king of Denmark to explore the interior of Arabia, and who fell a sacrifice to the pestilential diseases of those inhospitable regions, discovered two new species. Thunberg, in his *Prodromus*, has mentioned five more. Forty new species have been discovered by Mr Masson of Kew Gardens, who was sent out by his present Majesty for the purpose of collecting plants round the Cape of Good Hope. Descriptions of these, with elegant and highly finished coloured engravings, have lately been published. They are chiefly natives of the extensive deserts called *Karro*, on the western side of the Cape.

STAR, in fortification, denotes a small fort, having five or more points, or saliant and re-entering angles, flanking one another, and their faces 90 or 100 feet long.

STARCH (see *Encycl.*) is commonly made of wheat, and the very best starch can perhaps be made of nothing else. Wheat, however, is too valuable an article of food to be employed as the material of starch, when any thing else will answer the purpose; and it has long been known that an inferior kind of starch may be made of potatoes. Potatoes, however, are themselves a valuable article of food; and it is therefore an object of importance to try if starch may not be made of something still less useful.

On the 8th of March 1796, a patent was granted to Lord William Murray for his discovery of a method by which starch may be extracted from horse-chesnuts. That method is as follows:

Take the horse-chesnuts out of the outward green prickly husks; and then either by hand, with a knife or other tool, or with a mill adapted for that purpose, carefully pare off all the brown rind, being particularly careful not to leave the smallest speck, and to entirely eradicate the sprout or growth. Next take the nuts, and rasp, grate, or grind them fine into water, either by hand, or by a mill adapted for that purpose. Wash the pulp, which is thereby formed in this water, as clean as possible, through a coarse horse-hair sieve; then again wash through a finer sieve, and then again through a still finer, constantly adding clean water to prevent any starch from adhering to the pulp. The last process is, to put it with a large quantity of water (about four gallons to a pound of starch) through a fine gauze, muslin, or lawn, so as entirely to clear it of all bran or other impurities. As soon as it settles, pour off the water; then mix it up with clean water, repeating this operation till it no longer imparts any green, yellow, or other colour to the water. Then drain it off till nearly dry, and set it to bake, either in the usual mode of baking starch, or else spread out before a brisk fire; being very attentive to stir it frequently to prevent its horning, that is to say, turning to a paste or jelly, which, on being dried, turns hard like horn. The whole process should be conducted as quickly as possible.

Mention is here made of a mill which may be employed to grind the horse-chesnuts; but none is described as proper for that purpose. Perhaps the following mill, which was invented by M. Baumé for grinding potatoes, with a view to extract starch from them, may answer for grinding horse chesnuts.

He had a grater made of plate iron, in a cylindrical form (fig. 1.) about seven inches in diameter, and about eight inches high: the burs made by stamping the holes are on the inside. This grater is supported upon three feet AAA, made of flat iron bars, seven feet high, strongly rivetted to the grater; the bottom of each foot is bent horizontally, and has a hole in it which receives a screw, as at A, fig. 4. A little below the upper end of the three feet is fixed a cross piece B (fig. 1. and 4.), divided into three branches, and rivetted to the feet. This cross piece not only serves to keep the feet at a proper distance from each other, and to prevent their bending; but the centre of it having a hole cut in it, serves to support an axis or spindle of iron, to be presently described.

The upper end of this cylindrical grater has a diverging border of iron C (fig. 1. 4. and 7.), about ten inches in diameter at the top, and five inches in height.

Within this cylindrical grater is placed a second grater (fig. 2. and 3.), in the form of a cone, the point of which is cut off. The latter is made of thick plate iron, and the burs of the holes are on the outside: it is fixed, with the broad end at the bottom, as in fig. 4. At the upper end of the cone is rivetted a small triangle, or cross piece of iron, consisting of three branches D (fig. 2.), in the middle of which is made a square hole, to receive an axis or spindle; to give more resistance to this part of the cone, it is strengthened by means of a cap of iron E, which is fixed to the grater by means of rivets, and has also a square hole made in it, to let the axis pass through.

Fig. 3. represents the same cone seen in front; the base F has also a cross piece of three branches, rivetted to a hoop of iron, which is fixed to the inner surface of the cone; the centre of this cross piece has also a square hole for the passage of the axis.

Fig. 5. is a spindle or axis itself; it is a square bar of iron about 16 inches long, and more than half an inch thick; round at the bottom, and also towards the top, where it fits into the cross piece I, fig. 7. and B, fig. 1. and 4.; in these pieces it turns round, and by them it is kept in its place. It must be square at its upper extremity, that it may have a handle, about nine inches long, fixed to it, by means of which the conical grater is turned round. At G, (fig. 5.), a small hole is made through the axis, to receive a pin H, by means of which the conical grater is kept [illegible] within the cylindrical one.

Fig. 6. is a bird's eye view, in [illegible] presented placed in an oval tub, li[illegible] is the fore-mentioned triangular iron cross, fixed with screws to the side of the tub; the centre of it has a round hole, for the axis of the mill to move in when it is used.

Fig. 7. represents the mill in the oval tub; it is placed at one end of it, that the other end may be left free for any operation to be performed in it which may be necessary. A part of the tub is cut off, that the inside of it, and the manner of fixing the mill, may be seen. That the bottom of the tub may not be worn by the screws which pass through the feet of the mill, a deal board, about an inch thick, and properly shaped, is placed under the mill.

When we wish to make use of this mill, it is to be fixed by the feet, in the manner already described; it is also fixed at the top, by means of the cross piece I, fig. 6. and 7. The tub is then to have water poured into

Starch.

into it as high as K, and the top of the mill is to be filled with potatoes, properly washed and cut; the handle L is to be turned round, and the potatoes, after being ground between the two graters, go out gradually at the lower part, being assisted by the motion produced in the water by the action of the mill.

It is not necessary, in the construction of such a mill, to be very particular with respect to its proportions; but, in order to make known those which experience has proved to be good ones, a scale is given with the figures, to which recourse may be had. With a mill of this size, 100 pounds of potatoes may be ground in the space of two hours.

We are persuaded that this mill will answer perfectly well for grinding horse-chesnuts; and we hope, that where they can be had they will be used in preference to potatoes. We shall, however, give M. Baumé's method of extracting starch from the ground potatoes, not only because it will be acceptable to those who have not horse-chesnuts, but also because those who have may, by following it, be able, perhaps, to make starch of them, without encroaching upon Lord William Murray's patent.

In order to prepare starch from potatoes, says M. Baumé, any quantity of these roots may be taken, and soaked in a tub of water for about an hour; they are afterwards to have their fibres and shoots taken off, and then to be rubbed with a pretty strong brush, that the earth, which is apt to lodge in the inequalities of their surface, may be entirely removed; as this is done, they are to be washed, and thrown into another tub full of clean water. When the quantity which we mean to make use of has been thus treated, those which are too large are to be cut into pieces about the size of eggs, and thrown into the mill; that being already fixed in the oval tub, with the proper quantity of water; the handle is then turned round, and as the potatoes are grated they pass out at the bottom of the mill. The pulp which collects about the mill must be taken off from time to time with a wooden spoon, and put aside in water.

When all the potatoes are ground, the whole of the pulp is to be collected in a tub, and mixed up with a great quantity of clean water. At the same time, another tub, very clean, is to be prepared, on the brim of which are to be placed two wooden rails, to support a hair sieve, which must not be too fine. The pulp and water are to be thrown into the sieve; the flour passes through with the water, and fresh quantities of water are successively to be poured on the remaining pulp, till the water runs through as clear as it is poured in. In this way we are to proceed till all the potatoes that were ground are used.

The pulp is commonly thrown away as useless; but it should be boiled in water, and used as food for animals; for it is very nourishing, and is about [illegible] of the whole quantity of potatoes used.

To return from this short digression. The liquor which has passed through the sieve is turbid, and of a brownish colour, on account of the extractive matter which is dissolved in it; it deposits, in the space of five or six hours, the flour which was suspended in it. When all the flour is settled to the bottom, the liquor is to be poured off and thrown away, being useless; a great quantity of very clean water is then to be poured upon the flour remaining at the bottom of the tub, which is to be stirred up in the water, that it may be washed, and the whole is to stand quiet till the day following. The flour will then be found to have settled at the bottom of the tub; the water is again to be poured off as useless, the flour washed in a fresh quantity of pure water, and the mixture passed through a silk sieve pretty fine, which will retain any small quantity of pulp which may have passed through the hair sieve. The whole must once more be suffered to stand quiet till the flour is entirely settled; if the water above it is perfectly clear and colourless, the flour has been sufficiently washed; but if the water has any sensible appearance either of colour or of taste, the flour must be again washed, as it is absolutely necessary that none of the extractive matter be suffered to remain.

When the flour is sufficiently washed, it may be taken out of the tub with a wooden spoon; it is to be placed upon wicker frames covered with paper, and dried, properly defended from dust. When it is thoroughly dry, it is to be passed through a silk sieve, that if any clotted lumps should have been formed they may be divided. It is to be kept in glass vessels stopped with paper only. See *Vegetable Substances*, Suppl.

N. B. Almost all the flour of potatoes that is to be bought contains a small quantity of sand, which is perceived between the teeth; it is owing to the potatoes not having been properly washed; for the sand which lodges in the knobs and wrinkles of these roots, is not always easy to get out.

Starch ‖ Steam.

STARLINGS, or STERLINGS, [illegible] to the strong pieces of timber [illegible] the bed of the river to [illegible] of which were laid the [illegible] the bases of the stone piers [illegible] London bridge. In general [illegible] placed on the outside of the [illegible] of bridges, to break the force of [illegible] protect the stone work from injury by [illegible]. They are otherwise called JETTEES, which [illegible]; and their place is often supplied by large stones thrown at random round the piers of bridges, as may be seen at Stirling bridge when the river is low, and as was done by Mr Smeaton's direction round the piers of the centre arch of London bridge, when it was thought in danger of being undermined by the current. See SMEATON, *Encycl.*

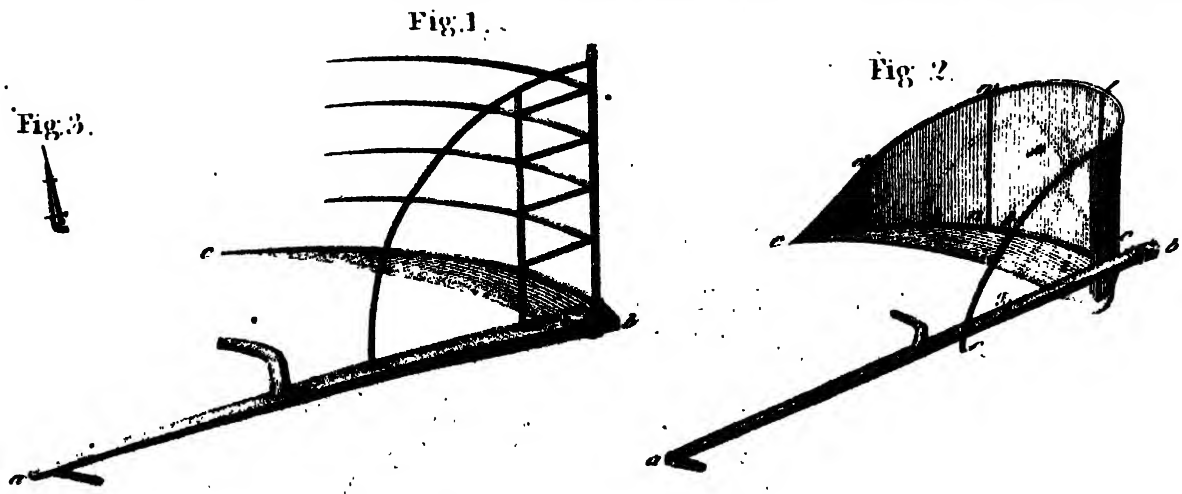
STATIONARY, in astronomy, the state of a planet when, to an observer on the earth, it appears for some time to stand still, or remain immoveable in the same place in the heavens. For as the planets, to such an observer, have sometimes a progressive motion, and sometimes a retrograde one, there must be some point between the two where they must appear stationary.

STEAM, STEAM-ENGINE. The few following corrections of these articles in the *Encycl.* were communicated by the author.

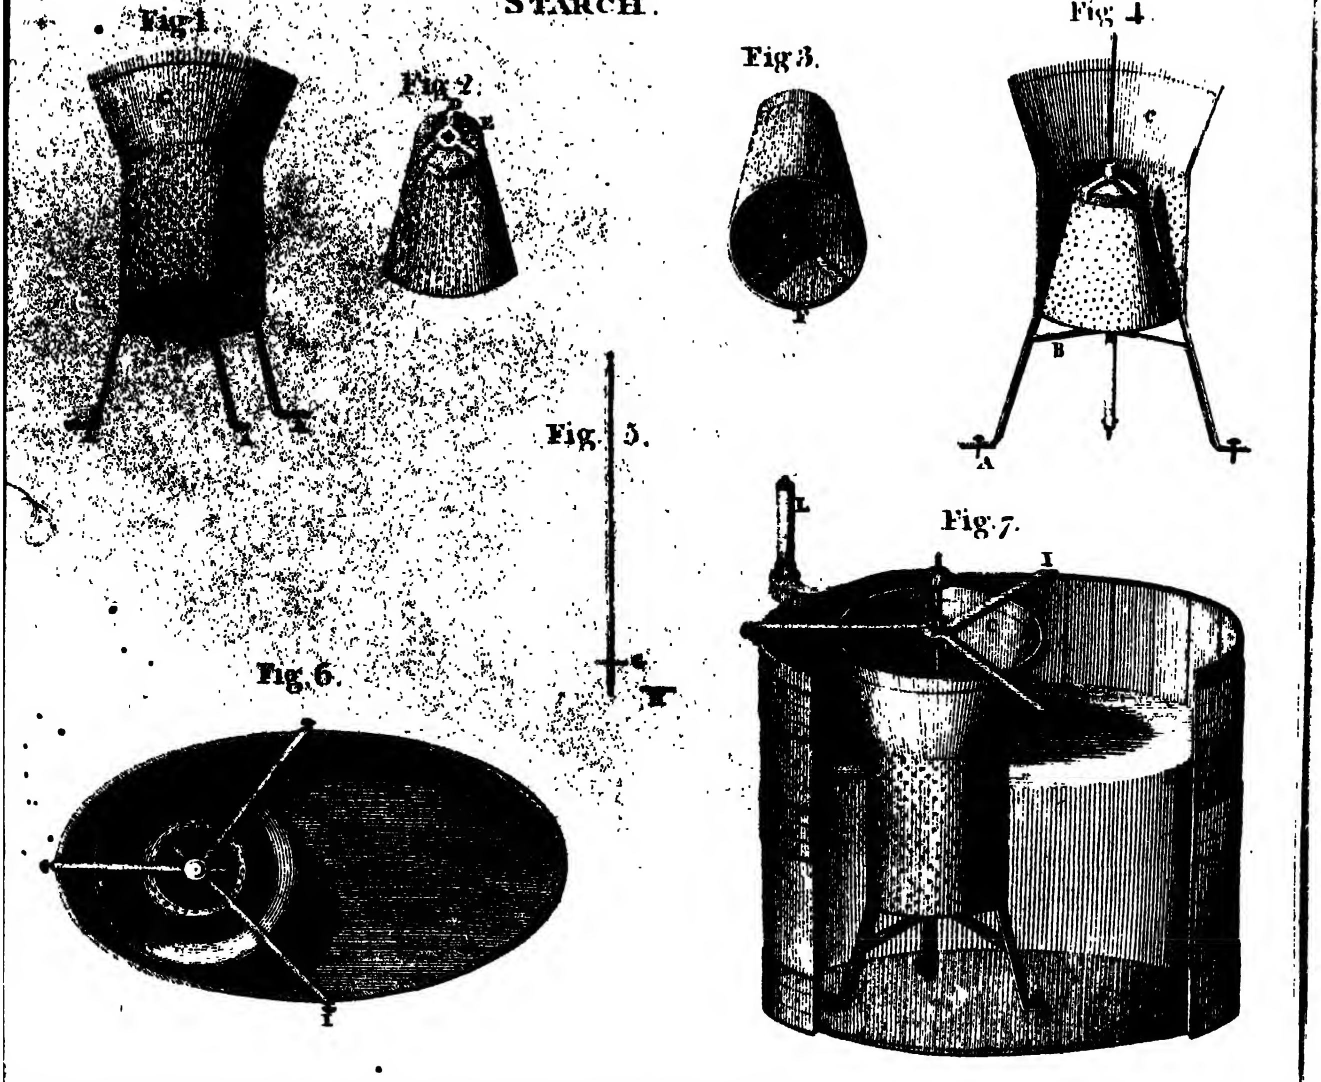
Page 745. col. 1.—It was not at the York Buildings waterworks in London that the boiler burst, but in the country in an engine erected by Dr Desaguilliers. See his *Experimental Philosophy*, Vol. II. p. 489.

Page 746. col. 2.—The condensation requires more cold water than is here allowed, as will appear by and bye; and we also suspect that the rapidity is overrated with which a great volume of steam is condensed by

REAPING SCYTHES PLATE XLII.



STARCH.



D. Lizars Sculpt.

by the cold surface of a vessel. We are well informed that Mr Watt was much disappointed in his expectations from a construction in which this mode of condensation was adopted. The condenser employed by Mr Cartwright (see *Phil. Mag.*) was one of the very first thought of and tried for this purpose, and was given up, as well as all others on the same principle; and the immediate contact of cold water was preferred as incomparably more effective. The great superiority of the capacity of water for heat is now well known. It is true, that when we employ an extensive cold surface of the condenser, this surface is kept cold by the water round it; and therefore we still avail ourselves of this great avidity of water for heat. But this water must act through the intervention of the vessel; and the substance of the vessel does not convey heat to the surrounding water in an instant.

Page 749. col. 2.—No distinct experiment shews so great an expansion of water, when converted into steam at the temperature 212°; and under the pressure of the air Mr Watt never found it more than 1800 times rarer than water.

Page 753. col. 1.—The heat expended in boiling off a cubic foot of water is about six times as much as would bring it to a boiling heat from the medium temperature (55°) in this climate.

Page 758. col. 2.—The quantity of water necessary for injection may be determined on principle, at least for an engine having a separate condenser. Every cubic foot of common steam produces about an inch of water when condensed, and contains about as much latent heat as would raise 1100 inches of water one degree. This steam must not only be condensed, but must be cooled to the temperature of the hot well; therefore as many inches of cold water must be employed as will require all this heat to raise it to the temperature of the hot well. Therefore let x be the cubic feet of steam, or capacity of the cylinder, and let y be the inches of cold water expended in condensing it. Let a be the difference between 212° and the temperature of the hot well, and b the difference between the temperature of the well and the injection cistern. We have $yb = x \times \overline{1100 + a}$, or $y = \frac{\overline{1100 + a} \times x}{b}$.

Thus, if the temperature of the hot well be 100° (and it should never be higher, if we would have a tolerable vacuum in the cylinder), and that of the injection cistern be 50°, we have $a = 112$, and $b = 50$, and $y = \frac{1212}{50} x, = 24{,}24\, x$, or $24\frac{1}{4}\, x$; that is, every foot of the capacity of the cylinder, or every inch of water evaporated from the boiler, requires more than 24 inches of water to condense the steam. A wine pint for every inch of water boiled off, or every cubic foot of capacity of the cylinder, may be kept in mind, as a large allowance. Or, more exactly, if the engine be in good order, and the injection water as low as 50°, and the hot well not above 100°, we may allow 25 gallons of injection for one gallon of water boiled off. This greatly exceeds the quantity mentioned in the case of a good Newcomen's engine, the cylinder of which contained almost 30 cubic feet of steam. And this circumstance shews the superiority of the engine with a separate condenser. The injection of Newcomen's engine had been adjusted by experience, so as to make the best compensation for the unavoidable waste in the cylinder. We presume that this machine was not loaded above eight pounds per inch, more likely with seven; whereas Watt's engine, working in the condition now described, bears a load not much below twelve, making at least twelve strokes per minute.

This is not a matter of mere curiosity; it affords a very exact rule for judging of the good working order of the engine. We can measure with accuracy the water admitted into the boiler during an hour, without allowing its surface to rise or fall, and the water employed for injection. If the last be below the proportion now given (adapted to the temperatures 50 and 100°), we are certain that steam is wasted by leaks, or by condensation in some improper place. The rule is not strictly conformable to the latent heat of steam which balances the atmosphere, 1100° being somewhat too great a value. It is accommodated to the actual performance of Watt's engines, when in their best working condition.

It is evident that it is of great importance to have the temperature of the hot well as low as possible; because there always remains a steam in the cylinder, of the same, or rather higher temperature, possessing an elasticity which balances part of the pressure on the other side of the piston, and thus diminishes the power of the engine. This is clearly seen by the barometer, which Mr Watt applies to many of his best engines, and is a most useful addition for the proprietor. It shews him, in every moment, the state of the vacuum, and the real power of his engine, and tells him when there are leaks by which air gets in.

Page 762. cols. 1. 2.—Mr Watt's first experiment was not exactly as here related, but much more analogous to the present form of his engine. The condenser was a cylinder of tinplate, fitted with a piston, which was drawn up from the bottom to the top, before the eduction cock was opened. Without this previous rarefaction in the condenser, there was no inducement for the steam to take this course, unless it were made much stronger than that of ordinary boiling water.

The description of the first form of the engine is also faulty, by the omission of a valve immediately below the eduction pipe. This valve is shut along with the valve I, to prevent the steam, which should then go into the lower part of the cylinder, from also going down into the condenser. This is not absolutely necessary, but its advantage is evident.

Page 766. col. 1.—This form of the engine was very early put in practice by Mr Watt—about the year 1775. The small engine at Mr Boulton's works at Soho was erected in 1776; and the engine at Shadwell waterworks, one of the best yet erected, had been working some time when we saw it in 1778. We mention this, because we have been told that Mr Hornblower puts in some claim to priority in this invention. We do not think that Mr Hornblower erected any of his engines before 1782; and as Mr Hornblower was, we believe, working with Boulton and Watt before that time, we think it fully more probable that he has in this respect profited by the instruction of such intelligent employers. We may also observe, that Mr Watt employed the same contrivance which we have described with much approbation in p. 772. *Encycl.* for keeping

 the

Steel

the collar round the piston rods steam and air tight. He found them effectual, but that they required more attention for keeping them in fit condition than the usual mode of packing. He made a similar packing for the piston, and with a similar result.

Page 769. col. 1. 2.—Mr Boulton estimates the performance of the engines in the following manner. Seeing that the great expence of the engine is the consumption of fuel, he makes this the standard of computation, and estimates the performance by the work which he *engages* to perform by the consumption of one bushel of good Newcastle coal, London measure, or containing 84 lbs without regard to the time in which this bushel is expended. This depends on the size of the engine.

The burning one bushel of coal will,

1. Raise 30 million pounds one foot high.
2. It will grind and dress 11 bushels of wheat.
3. It will slit and draw into nail rods 5 cwt. of iron.
4. It will drive 1000 cotton spindles, with all the preparation machinery, with the proper velocity.
5. It is equivalent to the work of ten horses.

The general performance of the double stroke expansive engines is somewhat beyond this; and their performance in cotton spinning, or as compared with horse work, is much under rated. The first estimation is without ambiguity. Suppose the engine of such a size as to consume a bushel of coals per hour. This will be found equivalent to raising 97 wine hogsheads of water ten feet high in a minute, which ten stout draught horses cannot do for a quarter of an hour together. They can raise 60 in that time, and work at this rate eight or perhaps ten hours from day to day.

Mr Watt finds that, with the most judiciously constructed furnaces, it requires eight feet of surface of the boiler to be exposed to the action of fire and flame to boil off a cubic foot of water in an hour, and that a bushel of coals so applied will boil off from eight to twelve cubic feet.

Boulton and Watt now make steam-engines equivalent in power to one or two horses. The cylinder and whole machinery does not occupy more room than a fine lady's working table, standing in a square of about 2½ feet, and about 5 feet high.

STEEL (see that article *Encycl* and CHEMISTRY, n° 114 *Suppl.*) is composed of iron and carbon. In addition to the old proofs which we had of this fact, it occurred to *Morveau*, alias *Guyton*, to attempt to convert soft iron into steel, by using the diamond instead of charcoal in the process of cementation. This expensive experiment, which was suggested by M. Clouet, was made, by inclosing within a small crucible of very soft iron a diamond, and shutting up the crucible by a stopper well adjusted. This crucible of iron, with its contents, was placed, without the addition of any surrounding matter, in a very small Hessian crucible, and the latter in a second crucible of the same earth; but the space between the two latter crucibles was filled with siliceous sand, free from all ferruginous particles. In the last place, the large crucible was luted with earth arising from pounded crucibles and unbaked clay, and the whole was exposed about an hour to a three blast forge fire. When the whole was cooled, the iron was found in the interior Hessian crucible converted into a solid ingot of cast steel. Thus the diamond disappeared by the affinity which iron exercised on it by the help of the high temperature to which they were both exposed, in the same manner as a metal disappears in the alloy of another metal. The diamond therefore furnished here the same principle as carbon, since the product of the union has the same properties.

The conversion into steel could not be doubted. The ingot having been polished on a lapidary's wheel, a drop of weak nitrous acid immediately produced a dark-grey spot, absolutely like that exhibited on English cast steel, and on cast steel produced by the process of C. Clouet. Those who have often tried steel by this kind of proof, long ago pointed out by Rinmann, had occasion to remark, that the spot of cast steel, tho' very sensible, is, however, less black than that of steel made by cementation, which depends perhaps on the different degree of oxydation of the carbon which they have taken in.

The process of M. Clouet here mentioned, for producing cast steel, consists in nothing more than throwing a quantity of glass into the mass of iron and charcoal during the formation of the former into steel. The same chemist has ascertained that iron, during its conversion into steel, absorbs 0.2013 of its weight of carbon; and that the affinity of iron for carbon is so strong, that, at a white heat, it is capable of decomposing carbonic acid gas. This he proved by the following experiment.

If six parts of iron be mixed with four parts of a mixture composed of equal quantities of carbonat of lime and clay, and kept in a crucible at a white heat, for an hour or longer, according to the quantity, the iron will be converted into steel. The decomposition of carbonic acid is evidently the consequence of a compound affinity; part of the iron combining with the carbon, and another part with the oxygen of the carbonic acid gas. Accordingly the commissioners, who were appointed to examine the process, remark, that a quantity of oxyd of iron was always mixed with the melted earthy substance, which was separated from the steel.

STEEVENS (George), the most successful of all the editors and commentators of Shakespeare, was born 1735. Of his parents we know nothing, but that they seem to have been in circumstances which may be deemed affluent. George received the rudiments of his classical education at Kingston-upon-Thames, under the tuition of Dr Woodeson and his assistants; and had for a companion at that school Gibbon the historian. From Kingston he went to Eton, whence, after some years, he was admitted a fellow-commoner of King's College, Cambridge; but with the course of his studies in the university we are not acquainted. If we might hazard a conjecture, from the manner in which he employed his riper years, we should suppose that he had little relish for those mathematical speculations which in Cambridge lead to academical honours. After he left the university, he accepted a commission in the Essex militia on its first establishment: and he spent the latter years of his life at Hampstead in almost total seclusion from the world; seldom mixing with society but in the shops of booksellers, in the Shakespeare Gallery, or in the morning *conversations* of Sir Joseph Banks. He died January 1800.

This

Steevens.

This is a very meagre account of the incidents which must have taken place in the life of a man so conspicuous in the republic of letters; but we have had no opportunity of improving it. His character, as drawn in the Monthly Magazine, believing it to be just, we shall adopt, as it will supply in some degree the defects of our narrative.

Though Mr Steevens is known rather as a commentator than as an original writer; yet, when the works which he illustrated, the learning, sagacity, taste, and general knowledge which he brought to the task, and the success which crowned his labours, are considered, it would be an act of injustice to refuse him a place among the first literary characters of the age. Adorned by a versatility of talents, he was indeed eminent both by his pen and his pencil. With the one there was nothing which he could not compose, and with the other there was nothing which he could not imitate so closely, as to leave a doubt which was the original and which the copy. But his chief excellence lay in his critical knowledge of an author's text; and the best specimen of his great abilities is his edition of Shakespeare, in which he has left every competitor far behind him. He had, in short, studied the age of Shakespeare, and had employed his persevering industry in becoming acquainted with the writings, manners, and laws of that period, as well as the provincial peculiarities, whether of language or custom, which prevailed in different parts of the kingdom, but more particularly in those where Shakespeare passed the early years of his life. This store of knowledge he was continually increasing, by the acquisition of the rare and obsolete publications of a former age, which he spared no expence to obtain; while his critical sagacity and acute observation were employed incessantly in calling forth the hidden meanings of the great dramatic bard, from their covert, and consequently enlarging the display of his beauties. This advantage is evident from his last edition of Shakespeare, which contains so large a portion of new, interesting, and accumulated illustration. In the preparation of it for the press, he gave an instance of editorial activity and perseverance, which is without example. To this work he devoted solely, and exclusively of all other attentions, a period of 18 months; and during that time he left his house every morning at one o'clock with the Hampstead patrole, and proceeded, without any consideration of the weather or the season, to his friend Mr Isaac Reed's chambers, in Barnard's Inn, where he was allowed to admit himself, and found a room prepared to receive him, with a sheet of the Shakespeare letter press ready for correction. There was every book which he might wish to consult; and to Mr Read he could apply, on any doubt or sudden suggestion, as to a man whose knowledge of English literature was perhaps equal to his own. This nocturnal toil greatly accelerated the printing of the work; as while the printers slept the editor was awake; and thus, in less than twenty months, he completed his last splendid edition of Shakespeare, in fifteen large octavo volumes; an almost incredible labour, which proved the astonishing energy and persevering powers of his mind.

That Mr Steevens contented himself with being a commentator, arose probably from the habits of his life, and his devotion to the muse, with which his own will descend to the latest posterity. It is probable that many of his *jeux d'esprit* might be collected: there is a poem of his in Dodsley's Annual Register, under the title of *The Frantic Lover*, which is superior to any similar production in the English language. Mr Steevens was a classical scholar of the first order. He was equally acquainted with the belles lettres of Europe. He had studied history, ancient and modern, but particularly that of his own country. He possessed a strong original genius, and an abundant wit; his imagination was of every colour, and his sentiments were enlivened with the most brilliant expressions. His colloquial powers surpassed those of other men. In argument he was uncommonly eloquent; and his eloquence was equally logical and animated. His descriptions were so true to nature, his figures were so finely sketched, of such curious selection, and so happily grouped, that he might be considered as a speaking Hogarth. He would frequently, in his sportive and almost boyish humours, condescend to a degree of ribaldry but little above O'Keefe—with him, however, it lost all its coarseness, and assumed the air of classical vivacity. He was indeed too apt to catch the ridiculous, both in characters and things, and indulge an indiscreet animation wherever he found it. He scattered his wit and his humour, his gibes and his jeers, too freely around him, and they were not lost for want of gathering.

Mr Steevens possessed a very handsome fortune, which he managed with discretion, and was enabled by it to gratify his wishes, which he did without any regard to expence, in forming his distinguished collections of classical learning, literary antiquity, and the arts connected with it. His generosity also was equal to his fortune; and though he was not seen to give eleemosynary sixpences to sturdy beggars or sweepers of the crossings, few persons distributed banknotes with more liberality; and some of his acts of pecuniary kindness might be named, which could only proceed from a mind adorned with the noblest sentiments of humanity. He possessed all the grace of exterior accomplishment, acquired at a period when civility and politeness were characteristics of a gentleman.

He has bequeathed his valuable Shakespeare, illustrated with near 1500 prints, to Lord Spencer; his Hogarth perfect, with the exception of one or two pieces, to Mr Windham; and his corrected copy of Shakespeare, with 200 guineas, to his friend Mr Read.

Stereometer.

STEREOMETER, an instrument lately invented in France for measuring the volume of a body, however irregular, without plunging it in any liquid. If the capacity of a vessel, or, which is the same thing, the volume of air contained in that vessel, be measured, when the vessel contains air only, and also when the vessel contains a body whose volume is required to be known, the volume of air ascertained by the first measurement, deducting the volume ascertained by the second, will be the volume of the body itself. Again, if it be admitted as a law, that the volume of any mass of air be inversely as the pressure to which it is subjected, the temperature being supposed constant, it will be easy to deduce, from the mathematical relations of quantity, the whole bulk, provided the difference between the two bulks under two known pressures be obtained by experiment.

Let it be supposed, for example, that the first pressure is double the second, or, which follows as a consequence,

quence, that the ſecond volume of the air be double the firſt, and that the difference be fifty cubic inches, it is evident that the firſt volume of the air will likewiſe be fifty cubic inches. The ſtereometer is intended to aſcertain this difference at two known preſſures.

Plate XLIII.

The inſtrument is a kind of funnel AB (fig. 1.), compoſed of a capſule A, in which the body is placed, and a tube B as uniform in the bore as can be procured. The upper edge of the capſule is ground with emery, in order that it may be hermetically cloſed with a glaſs cover M ſlightly greaſed. A double ſcale is paſted on the tube, having two ſets of graduations; one to indicate the length, and the other the capacities, as determined by experiment.

When this inſtrument is uſed, it muſt be plunged in a veſſel of mercury with the tube very upright, until the mercury riſes within and without to a point C of the ſcale. See fig. 2.

The capſule is then cloſed with the cover, which being greaſed will prevent all communication between the external air and that contained within the capſule and tube.

In this ſituation of the inſtrument, in which the mercury ſtands at the ſame height within and without the tube, the internal air is compreſſed by the weight of the atmoſphere, which is known and expreſſed by the length of the mercury in the tube of the common barometer.

The inſtrument is then to be elevated, taking care to keep the tube conſtantly in the vertical poſition. It is repreſented in this ſituation, fig. 2. ſecond poſition. The mercury deſcends in the tube, but not to the level of the external ſurface, and a column DE of mercury remains ſuſpended in the tube, the height of which is known by the ſcale. The interior air is therefore leſs compreſſed than before, the increaſe of its volume being equal to the whole capacity of the tube from C to D, which is indicated by the ſecond ſcale.

It is known therefore that the preſſures are in proportion to the barometrical column, and to the ſame column diminiſhed by the ſubtraction of DE. And the bulks of the air in theſe two ſtates are inverſely in the ſame proportion; and again the difference between theſe bulks is the abſolute quantity left void in the tube by the fall of the mercury; from which data, by an eaſy analytical proceſs, the following rule is deduced: Multiply the number which expreſſes the leſs preſſure by that which denotes the augmentation of capacity, and divide the product by the number which denotes the difference of the preſſures. The quotient will be the bulk of the air when ſubject to the greater preſſure.

To render this more eaſy by an example, ſuppoſe the height of the mercury in the barometer to be 78 centimetres, and the inſtrument being empty to be plunged in the mercury to the point C. It is then covered, and raiſed until the ſmall column of mercury DE is ſuſpended, for example, at the height of ſix centimetres. The internal air, which was at firſt compreſſed by a force repreſented by 78 centimetres, is now compreſſed only by a force repreſented by 78—6, or 72 centimetres.

Suppoſe it to be obſerved, at the ſame time, by means of the graduations of the ſecond ſcale, that the capacity of the part CD of the tube which the mercury has quitted is two cubic centimetres. Then by the rule $\frac{72}{6} \times 2$ give 24 cubical centimetres, which is the volume of the air included in the inſtrument when the mercury roſe as high as C in the tube.

The body of which the volume is to be aſcertained muſt then be placed in the capſule, and the operation repeated. Suppoſe, in this caſe, the column of mercury ſuſpended to be eight centimetres, when the capacity of the part CD of the tube is equal to two centimetres cube. Then the greateſt preſſure being denoted by 78 centimetres, as before, the leaſt will be 70 centimetres, the difference of the preſſures being 8, and the difference of the volumes two cubical centimetres. Hence $\frac{70}{8} \times 2$ gives the bulk of the included air under the greateſt preſſure 17,5 cubic centimetres. If therefore 17,5 centimetres be taken from 24 centimetres, or the capacity of the inſtrument when empty, the difference 6,5 cubic centimetres will expreſs the volume of the body which was introduced. And if the abſolute weight of the body be multiplied by its bulk in centimetres, and divided by the abſolute weight of one cubic centimetre of diſtilled water, the quotient will expreſs the ſpecific gravity of the body in the common form of the tables where diſtilled water is taken as unity, or the term of compariſon.

After this deſcription and explanation of the uſe of his inſtrument, the author proceeds with the candour and acuteneſs of a philoſopher to aſcertain the limits of error in the reſults; an object ſeldom ſufficiently attended to in the inveſtigation of natural phenomena. From his reſults it appears, that with the dimenſions he has aſſumed, and the method preſcribed for operating, the errors may affect the ſecond figure. He likewiſe gives the formulæ by means of which the inſtrument itſelf may be made to ſupply the want of a barometer in aſcertaining the greateſt preſſure. He likewiſe adverts to the errors which may be produced by change of temperature. To prevent theſe as much as poſſible, the actual form of the inſtrument and arrangements of its auxiliary parts are ſettled, as in fig. 3. by which means the approach of the hand near the veſſel and its tube is avoided. In this figure the vertical poſition of the tube is ſecured by the ſuſpenſion of the veſſel, and a perforation in the table through which the tube paſſes. The table itſelf ſupports the capſule in its firſt poſition, namely, that at which the cover is required to be put on.

Mr Nicholſon, from whoſe Journal this abſtract is immediately taken, ſuppoſes, with great probability, that the author of the invention had not finiſhed his meditations on the ſubject, when the memoir giving an account of it was publiſhed. If he had, ſays the ingenious journaliſt, it is likely that he would have determined his preſſures, as well as the meaſures of bulk, by weight. For it may be eaſily underſtood, that if the whole inſtrument were ſet to its poſitions by ſuſpending it to one arm of a balance at H (fig. 3.), the quantity of counterpoiſe, when in equilibrio, might be applied to determine the preſſures to a degree of accuracy much greater than can be obtained by linear meaſurement.

STEWART-DENHAM (Sir James) was born at Edinburgh on the 10th of October, O. S. in the year 1713. His father was Sir James Stewart of Goodtrees, Bart. Solicitor-general for Scotland; and his mother

ther was Anne, daughter of Sir Hugh Dalrymple of North Berwick, Bart. president of the college of justice.

The first rudiments of his education he received at the grammar-school of North-Berwick, which at the time of his father's death he quitted at the age of fourteen, with the reputation of being a good scholar, but without any extraordinary advancement in knowledge.

It is remarkable, that many men who have been singularly useful to society have not shewn early symptoms of the greatness of their intellectual powers. A great understanding must be the offspring of happy organization in a healthy body, with co-operation of time, of circumstance, and of institution, without being forced into prematurity by excessive cultivation. This holds with respect to the growth and perfection of every creature; and the truth appears remarkable with respect to our own species, because we are apt to mistake the flimsy attainments of artificial education for the steady and permanent foundations of progressive knowledge.

From the school of North-Berwick Sir James was sent to the university of Edinburgh, where he continued until the year 1735, when he passed advocate before the Court of Session, and immediately afterwards went abroad to visit foreign countries. He was then in the 22d year of his age, had made himself well ac- [illegible] the Roman law and history, and the municipal law of Scotland. He had likewise maturely studied the elements of jurisprudence; was versed in the general, as well as the particular, politics of Europe; and was bent upon applying his knowledge to the investigation of the state of men and of manners in other nations, with a view to promote the benefit of his own, and to confirm himself in the love of a free constitution of government, by contemplating the baneful effects of unlimited monarchy in Germany, Italy, and Spain, and of extravagant attachment to a king and nobility, to war, and to pernicious splendour in France.

He travelled first, however, into Holland, with a view to study the constitution of the empire before he should visit Germany, and to attend some of the lectures of the most eminent professors at Utrecht and Leyden, on public law and politics. From thence he passed into Germany, resided about a year in France, travelled thro' some part of Spain, where he had a fever, that obliged him, for his perfect recovery from its effects, to go by the advice of his friends to the sea-coast of the lovely province of Valencia; thence returning, he crossed the Alps, and by Turin made the tour of Italy, where chiefly at Rome and Florence he resided till the beginning of the year 1740; when, having spent five years on his travels, he returned to Scotland, and married the Lady Frances Wemyss, eldest daughter of the Earl of Wemyss, about two years after his return.

A few months after his marriage the representation of the county of Mid-Lothian became vacant, by the member being made a lord of trade and plantation. The candidates were the late member and Sir John Baird of Newbyth. On the day of election Mr Dundas of Arniston, one of the senators of the college of justice, was chosen preses of the meeting; and some how or other omitted to cause the name of Sir James Stewart to be called on the roll of freeholders. For this illegal use of his temporary power, Sir James commenced a suit against the president; and resuming the gown as an advocate, pleaded his own cause with great energy and eloquence, and with the applause of the bench, the bar, and the public. This called Lord Arniston from the bench to plead in his own defence at the bar; and Sir James could not have been opposed to an antagonist better qualified to call forth all his powers; for that judge is talked of at this day in Edinburgh as the profoundest lawyer and the ablest pleader that ever graced the Scottish bench or the Scottish bar.

With the issue of this contest we are not acquainted; but it drew upon Sir James Stewart very general attention, and convinced the public, that had he continued at the bar, he must have risen rapidly to the head of his profession. On his travels, however, he had contracted friendships with Lord Marischal, and other eminent men, attached to the pretensions of the royal family of Stuart, and had received flattering attentions from the Pretender to the British throne; the impression arising from which, added to the irritations of his controversy with the powerful party in Scotland attached to the court, led him, unadvisedly, into connections with the movers of the rebellion in 1745.

As he was by far the ablest man of their party, the Jacobites engaged him to write the Prince Regent's manifesto, and to assist in his councils. Information having been given of his participation in these affairs, he thought it prudent, on the abortion of this unhappy attempt, to leave Britain; and by the zeal, it is said, of Arniston, he was excepted afterwards from the bill of indemnity, and rendered an exile from his country.

He chose France for his residence during the ten first years of his banishment, and was chiefly at Angoulesme, where he superintended the education of his son; from thence he went to Tubingen in Suabia, for the benefit of its university, in prosecution of the same dutiful and laudable design; but in the end of the war 1756, having been suspected by the court of Versailles of communicating intelligence to the court of London, he was seized at Spa, and kept some time in confinement; from which being liberated, after the accession of the present king of Great Britain, he came, by toleration, to England, and resided at London, where he put the last hand to his System of Political Economy, the copy-right of which he sold to Andrew Millar; and being permitted to dedicate this work to the king, he applied for a *noli prosequi*, which, after some malicious objections, he obtained, and had the comfort of returning to his family estate in Scotland.

Having nothing professional to do during his long residence in France, the active mind of Sir James was occupied in study. His book on the Principles of Political Economy contains most of the fruits of it. He turned himself, in the intervals of leisure, to consider the resources of France, that he might the better compile that part of his great work which was to treat of revenue and expenditure. It was by studying the language of the finances, without which nobody can ask a proper question concerning them, so as to be understood, that he attained his great purpose.

As soon as he could ask questions properly, he applied in familiar conversation to the intendants and their substitutes in the provinces where he resided, whom he found extremely desirous to learn the state of the British finances, under the branches of the land-tax, customs, excise, and other inland duties. This led him to compare

Stewart-Denham

compare the ſtate of the two nations. The information he gave was an equivalent for the information he received; curioſity balanced curioſity, each was ſatisfied and informed. The department of the intendants in France was confined to the taxes which compoſed the *recettes generales*, namely, the *taille*, the *capitation*, and the *vingtiemes*, or *vingtiemes*. All the intendants had been *Maitres des Requetes*, bred at Paris, and could not fail to have much knowledge of the general *fermes* and other branches of the revenue. He carefully noted down at all times the anſwers he got; and when he came to reſide at Paris, he obtained more ample information, both from the gentlemen of the revenue, and from perſons of the parliament of Paris, who to the number of 25 had been for 15 months exiled in the province where he had ſo long reſided at Angouleſme.

With theſe advantages, with much ſtudy and attention to arrangement, he was enabled to compoſe the ſixth chapter of the fourth part of the fourth book of his Syſtem of Political Economy; a portion of that great work well worthy the attention of thoſe who wiſh to know the ſtate of France in reſpect of revenue under the old government.

Although Sir James Stewart's leiſure, during the firſt ten years of his exile, was chiefly employed in ſocial intercourſe with the moſt learned, elegant, and poliſhed characters in France, who delighted in the converſation and friendſhip of a man who poſſeſſed at once immenſe information, on almoſt every ſubject, important or agreeable to ſociety, and the talent of clearly and beautifully expreſſing his ſentiments in flowing and animated converſation; yet he did not allow the pleaſures of the circle and of the table to blunt the fine feelings of a man of genius and ſcience. The labour of collecting materials for his great political work was oppreſſive, and he relieved himſelf with various enquiries, ſuited to the exalted ambition of his cultivated underſtanding, while he turned the charms of converſation to the permanent delight of his aſſociates and of poſterity. The motto of Apelles, "*Nulla dies ſine linea*," was the emblem of his employment; and it is amazing what may be done by daily attention for improvement, without appearing to abſtract any extraordinary time from the common offices and rational pleaſures of ſociety.

In the beginning of the year 1755, Sir James wrote his Apology, or Defence of Sir Iſaac Newton's Chronology, which at that time he intended to publiſh, but was prevented by other engagements. It was communicated to ſeveral perſons of eminence in France and Germany in MS. and produced, in the month of December that year in the "*Mercure de France*," an anſwer from M. Deſhoulieres, to which Sir James ſoon after replied.

The great Newton, applying aſtronomical and ſtatiſtical principles to the ancient chronology of Greece, had chaſtiſed the vanity of nations, and arreſted the progreſs of infidelity in delineating the hiſtory of the world. Loſt in the confuſion of exceſſive pretenſions to an antiquity beyond all meaſure, and diſguſted by the ſuperſtitious aids that were aſſumed to ſupport theſe pretenſions among ancient nations, the revivers of learning in Europe, during the laſt and the preceding century, turmoiled themſelves with controverſies between the comparative merits of the ancients and moderns; and the abettors of the latter, entrenching themſelves behind the falſehoods of the ancients, on the ſcope of their remote hiſtory, gave the lie to all antiquity, and in deſpair plunged themſelves into the ocean of ſcepticiſm.

Happy had it been for ſociety if this ſcepticiſm had confined itſelf to the hiſtory of ancient nations in general: but the ſame ſpirit, taking diſguſt at the horrors of Chriſtian ambition and bigotry, and contemplating with deriſion the ridiculous legends of modern miracles, gave the lie to all religious ſcripture of the Jews and Chriſtians, and attempted to baniſh divine intelligence, the ſuperintending providence of Deity, and the true dignity of the human ſpecies, from the face of the earth!

It was a noble undertaking, therefore, in Sir James, to attempt to diſperſe this miſt of error, by diſpaſſionately and ſcientifically explaining and ſupporting the chronology of Sir Iſaac Newton. He has done it with great preciſion and effect; and it is a book well worth the peruſal of thoſe who wiſh to read ancient hiſtory with improvement, or to prevent themſelves from being bewildered in the mazes of modern conjecture. It was printed in 4to at Franckfort on the Maine, for John Bernard Eichemberg the Elder, in 1757.

In the year 1758, and the following, the Britiſh Houſe of Commons took up the conſideration of a ſtatute to regulate a general uniformity of weights and meaſures throughout the united kingdoms, which had been ſo often unſucceſsfully attempted.

This called the attention of Sir James, not only to the inveſtigation of the particular ſubject that engaged that of the Houſe of Commons, but to deviſe a method of rendering an uniformity of weights and meaſures univerſal. He thought the cauſe of former diſappointments in this uſeful purſuit had been the miſtaken notion that one or other of our preſent meaſures ſhould be adopted for the new ſtandard. After the plan had been relinquiſhed by the parliament of England, he digeſted his notes and obſervations on this important diſquiſition into the form of an epiſtolary diſſertation, which he tranſmitted to his friend Lord Harrington, and reſolved, if there had been a congreſs aſſembled, as was once propoſed, to adjuſt the preliminaries of the general peace in 1763, to have laid his plan before the miniſters of the different nations, who were to prepare that ſalutary pacification of the contending powers.

This epiſtolary diſſertation Sir James afterwards reduced at Coltneſs, in the year 1777, into a form more proper for the public eye, and ſent a corrected copy to a friend, reſerving another for the preſs, which was printed 1790 for Stockdale in Piccadilly.

In this tract the author ſhews, from the ineffectual attempts that have been made to alter partially, by innovation, the ſtandards of meaſures or weights, that the effectual plan to be adopted, is to depart entirely from every meaſure whatſoever now known, and to take, *ad libitum*, ſome new maſs inſtead of our pound, ſome new length inſtead of our ell, ſome new ſpace inſtead of our acre, and ſome new ſolid inſtead of our gallon and buſhel.

For this purpoſe Sir James propoſes as the unit a maſs to be verified with the greateſt poſſible accuracy, equal in weight to ten thouſand Troy grains. The pendulum, as it ſwings at London, to beat ſeconds of time,

Stewart. time, he proposes to be the measure of length; and after having laid down his fundamental principles, he proposes an ingenious plan for rendering their adoption universal through the whole world.

Having obtained his pardon, Sir James Stewart retired to Coltness, in the county of Lanark, the paternal estate of his family, where he turned his attention to the improvement of his neighbourhood by public works and police, and drew the first good plan for a turnpike bill, suited to the circumstances of Scotland, which has been since generally adopted. He repaired his house, planted, improved, and decorated his estate, and in social intercourse rendered himself the delight of his neighbourhood and country.

Never was there a man who, with so much knowledge, and so much energy of expression in conversation, rendered himself more delightful to his company, or was more regretted by his acquaintance when he died. Nor was the active mind of Sir James unemployed for the general benefit of his country during his retreat. He was engaged by the directors of the East India Company of England to digest a code for the regulation of the current coin of Bengal; the plan for which important regulation he printed, and received from the court of directors a handsome diamond ring, as a mark of their approbation.

He prepared for the press, but never published, an antidote to the *Système de la Nature* by Mirabeau, wherein the paralogisms and foolish reasoning of that infidel work are examined, detected, and confuted. It is written in French; and were the work of Mirabeau worth refutation, might be printed with much advantage to Sir James's reputation as a controversial writer.

This great and good man died in November 1780, and was buried at Cambusnethan, in Lanarkshire, on the [illegible] of the same month; the Duke of Hamilton and [illegible] performing the last offices to the remains of their highly valued friend, and bedewing his ashes with their tears.

For this short sketch of the principal events in the life of Sir James Stewart-Denham, we are indebted to his nephew the Earl of Buchan, who, justly proud of his relation to such a man, cannot be supposed to view all his projects, or even all his reasonings, with the cold impartiality of strangers. His plan, for instance, of a universal standard of weights and measures for the *whole world*, though certainly a grand conception, we cannot help considering as romantic and impracticable. The author indeed was sensible, that time would be requisite for its execution; and so large a portion of time, that, compared with it, a thousand years are but as one day, when compared with the ordinary life of man: but schemes of this magnitude are not for creatures so blind and weak as we are, who, when we wander to a distance beyond the limits of our narrow sphere, with the ambitious view of benefiting posterity, are almost certain to injure ourselves, without a probability of serving those for whom we dream that we are exerting our abilities. Sir James's Political Economy, however, is a very great work, which has not received half the praises to which it is entitled, and which, we suspect, provoked the envy of another great writer on similar subjects, who exerted himself privately to lessen its fame. The defence of Newton's chronology is likewise very valuable, though we certainly do not think that part of the system invulnerable, in which the great astronomer attempts to prove, that *Osiris*, *Sesostris*, and *Sesac*, are three names of the same Egyptian king. This, however, is a very trifling mistake; and the modern sciolist, who can lay hold of it to reject the whole, has certainly never read, or, if he has read, does not understand the defence of the system by Sir James Stewart.

SUBCONTRARY POSITION, in geometry, is when two equiangular triangles are so placed, as to have one common angle at the vertex, and yet their bases not parallel; consequently the angles at the bases are equal, but on the contrary sides.

SUBDUCTION, in arithmetic, the same as *Subtraction*.

ANIMAL AND VEGETABLE SUBSTANCES.

THE reader will recollect, that the article CHEMISTRY, in this *Supplement*, was divided into four parts; of which only the first three, comprehending the elements of the science, were given under the word CHEMISTRY. The *fourth part*, which was entitled an examination of bodies as they are presented to us by nature in the mineral, vegetable, and animal kingdoms,

1 Nature of the article.

naturally subdivides itself into three parts, comprehending respectively, 1. Minerals; 2. Vegetables; 3. Animals.

The first of these subdivisions, which has been distinguished by the name of MINERALOGY, we have treated of already in a former part of this Volume. As the other two subdivisions have not hitherto received any appropriate name, we have satisfied ourselves with the word SUBSTANCE, by which chemists have agreed to denote the objects which belong to these subdivisions. This name, it must be acknowledged, is not unexceptionable, but we did not consider ourselves as at liberty to invent a new one.

The present article, then, seems to divide itself into two parts: the first part comprehending *vegetable*; the second *animal* substances. But there are certain animal and vegetable substances distinguished from all others by being used as articles of clothing. It is usual to tinge these of various colours, by combining with them different colouring matters for which they have an affinity. This process, well known by the name of DYEING, is purely chemical; and as it belongs exclusively to animal and vegetable substances, it comes naturally to be examined here. We shall therefore add a *third part*, in which we shall give a view of the present state of DYEING, as far, at least, as is consistent with the nature of a supplementary article.

Division of it.

Part I. Of Vegetable SUBSTANCES.

Sugar. Vegetables, or plants, as they are also called, are too well known to require any definition. Their number is prodigious, and their variety, regularity, and beauty, are wonderful. But it is not our intention in this place either to enumerate, to describe, or to classify plants. These tasks belong to the botanist, and have been successfully accomplished by the zeal, the singular address, and the indefatigable labour of Linnæus and his followers.

4 Chemical examination of vegetables.

It is the business of the chemist to analyse vegetables, to discover the substances of which they are composed, to examine the nature of these substances, to investigate the manner in which they are combined, to detect the processes by which they are formed, and to ascertain the chemical changes to which plants, after they have ceased to vegetate, are subject. Hence it is evident, that a chemical investigation of plants comprehends three particulars:

1. An account of the *substances* of which plants are composed.

2. An account of the *vegetation* of plants, as far as it can be illustrated by chemistry.

3. An account of the *changes* which plants undergo after they cease to vegetate.

We therefore divide this part into three chapters, assigning a chapter to each of these particulars.

Chap. I. Of the Ingredients of Plants.

The substances hitherto found in the vegetable kingdom, all of them at least which have been examined with any degree of accuracy, may be reduced to the following heads:

1. Sugar,	10. Camphor,
2. Starch,	11. Resins,
3. Gluten,	12. Caoutchouc,
4. Albumen,	13. Wax,
5. Gum,	14. Wood,
6. Jelly,	15. Acids,
7. Extract,	16. Alkalies,
8. Tan,	17. Earths,
9. Oils,	18. Metals.

These shall form the subject of the following sections:

Sect. I. *Of Sugar.*

Sugar, which at present forms so important an article in our food, seems to have been known at a very early period to the inhabitants of India and China.

4 Discovery of sugar.

But Europe probably owes its acquaintance with it to the conquests of Alexander the Great. For ages after its introduction into the west, it was used only as a medicine; but its consumption gradually increased, and during the time of the Crusades, the Venetians, who brought it from the east, and distributed it to the northern parts of Europe, carried on a lucrative commerce with sugar. It was not till after the discovery of America, and the extensive cultivation of sugar in the West Indies, that its use in Europe, as an article of food, became general *.

Sugar is obtained from the *arundo saccharifera*, or *sugar cane*. The juice of this plant is pressed out and boiled in as low a temperature as possible, till the sugar precipitates in the form of confused crystals. These crystals, known by the name of *raw sugar*, are again dissolved in water, the solution is clarified, and purer crystals are obtained by a subsequent evaporation. But for the particulars of the art of manufacturing sugar, we refer the reader to the article Sugar in the *Encyclopedia*.

Sugar. 5 How obtained.

6 Its properties.

Sugar, after it has been purified, or *refined* as the manufacturers term it, is usually sold in Europe in the form of a white opake mass, well known by the name of *loaf sugar*. Sometimes also it is crystallized, and then it is called *sugar candy*.

Sugar has a very strong sweet taste; when pure it has no smell; its colour is white, and when crystallized it is somewhat transparent. It has often a considerable degree of hardness; but it is always so brittle that it can be reduced without difficulty to a very fine powder. It is not altered by exposure to the atmosphere.

It is exceedingly soluble in water. At the temperature of 48°, water, according to Mr Wenzel, dissolves its own weight of sugar. The solvent power of water increases with its temperature; when nearly at the boiling point, it is capable of dissolving any quantity of sugar whatever. Water thus saturated with sugar is known by the name of *syrup*. 7 Solubility in water.

Syrup is thick, ropy, and very adhesive; when spread thin upon paper, it soon dries, and forms a kind of varnish, which is easily removed by water. Its specific caloric, according to the experiments of Dr Crawford, is 1.086. When syrup is [illegible] crystallized, the sugar which it contains [illegible]. 8 The primitive form of these crystals [illegible] prism, whose base is a rhomb, [illegible] to its breadth as 10 to 7; and whose [illegible] proportion between the length and breadth of the base. The crystals are usually four or six-sided prisms, terminated by two sided, and sometimes by three-sided summits †.

Sugar is soluble in alcohol, but not in so large a proportion as in water. According to Wenzel, four parts of boiling alcohol dissolve one of sugar §. It unites readily with oils, and renders them miscible with water. A moderate quantity of it prevents, or at least retards, the coagulation of milk; but Scheele discovered that a very large quantity of sugar causes milk to coagulate ‖. 9 Solubility in alcohol.

Sugar absorbs muriatic acid gas slowly, and assumes a brown colour and very strong smell ‡.

Sulphuric acid, when concentrated, readily decomposes sugar; water is formed, and perhaps also acetous acid; while charcoal is evolved in great abundance, and gives the mixture a black colour, and a considerable degree of consistency. The charcoal may be easily separated by dilution and filtration. When heat is applied the sulphuric acid is rapidly converted into sulphurous acid. 10 Action of acids.

When sugar is mixed with potash, the mixture acquires a bitter and astringent taste, and is insoluble in alcohol, though each of the ingredients is very soluble in that liquid. When the alkali is saturated with sulphu- 11 Of potash.

* See Falconer's History of Sugar, Manchester Memoirs, iv. 291. and Moseley's Treatise on Sugar.

† Gillot, Ann. de Chim. xviii. 317.

§ Enc. Meth. Chim. i. 271.

‖ Scheele ii. 52. Dijon translation.

‡ Priestley, ii. 291.

Sugar

ric acid, and precipitated by means of alcohol, the sweet taste of the sugar is restored; a proof that it had undergone no decomposition from the action of the potash, but had combined with it in the state of sugar *.

* Cruickshank Roll'o on Diabetes, p. 452.

12 Of lime.

Lime boiled with sugar produces nearly the same effect as potash; when an alkali is added to the compound, a substance precipitates in white flakes. This substance is sugar combined with lime †. Sugar and chalk compose, as Leonardi informs us, a kind of cement ‡.

† Ibid.

‡ Encyc. Meth. Chim i. 271.

13 Of heat.

Sugar, when thrown upon a hot iron, melts, swells, becomes brownish black, emits air bubbles, and exhales a peculiar smell, known in French by the name of *caromel*. At a red heat it instantly bursts into flames with a kind of explosion. The colour of the flame is white with blue edges.

14 Distillation of it.

When sugar is distilled in a retort, there comes over a fluid which, at first, scarcely differs from pure water; by and bye it is mixed with pyromucous acid, afterwards some empyreumatic oil makes its appearance; and a bulky charcoal remains in the retort. This charcoal very frequently contains lime, because lime is used in refining sugar; but if the sugar, before being submitted to distillation, be dissolved in water, and made to crystallize by evaporation in a temperature scarcely higher than that of the atmosphere, no lime whatever, nor any thing else, except pure charcoal, will be found in the retort. During the distillation, there comes over a considerable quantity of carbonic acid, and carbonated hydrogen gas *. Sugar therefore is decomposed by the action of heat; and the following compounds are formed from it: Water, pyromucous acid, oil, charcoal, carbonic acid, carbonated hydrogen gas. The quantity of oil is inconsiderable; by far the most abundant product is pyromucous acid. Sugar indeed is very readily converted into pyromucous acid; for it makes its appearance always whenever syrup is raised to the boiling temperature. Hence the smell of caromel, which syrup at that temperature emits. Hence also the reason that, when we attempt to crystallize syrup by heat, there always remains behind a quantity of incrystallizable matter, known by the name of *molasses*; whereas if the syrup be crystallized without artificial heat, every particle of sugar may be obtained from it in a crystalline form †. Hence we see the importance of properly regulating the fire during the crystallization of sugar, and the immense saving that would result from conducting the operation at a low heat.

* Scopoli and Morveau, Enc. Meth. Chim. i. 269.

† Morveau, Enc. Meth. Chim. i. 266.

15 Its composition.

It follows from these facts, and from various other methods of decomposing sugar, that it is composed of oxygen, hydrogen, and carbon; for all the substances obtained from sugar by distillation may be resolved into these elements. Lavoisier has made it probable, by a series of very delicate experiments, that these substances enter into the composition of sugar in the following proportions:

64	oxygen,
28	carbon,
8	hydrogen.
100	

Of the way in which these ingredients are combined in sugar, we are still entirely ignorant. Lavoisier's conclusions can only be considered as approximations to the truth.

Sugar is considered as a very nourishing article of food. It is found most abundantly in the juice of the sugar cane, but many other plants also contain it. The juice of the acer saccharinum, or *sugar maple*, contains so much of it, that in North America sugar is often extracted from that tree *. Sugar is also found in the roots of carrot, parsnip, beet, &c. Mr Achard has lately pointed out a method of increasing the quantity of sugar in beet so much, that, according to his own account, it is at present cultivated in large quantities in Prussia, and sugar extracted from it with advantage †. Parmentier has also ascertained that the grains of wheat, barley, &c. and all the other similar seeds which are used as food, contain at first a large quantity of sugar, which gradually disappears as they approach to a state of maturity. This is the case also with peas and beans, and all leguminous seeds, and is one reason why the flavour of young peas is so much superior to that of old ones.

Starch.

16 Plants containing it.

* [illegible] ii. 64.

† Ann. de Chim xxxvi. 163.

SECT. II. *Of Starch.*

17 Method of obtaining starch.

When a quantity of wheat flour is formed into a paste, and water poured upon it till it runs off colourless, this water soon deposits a very fine whitish powder; which, when properly washed and dried, is known by the name of *starch*. When first prepared, it is of a grey colour; but the starchmakers render it white by steeping it in water slightly acidulated. The acid seems to dissolve and carry off the impurities.

Starch was well known to the ancients. Pliny informs us, that the method of obtaining it was first invented by the inhabitants of the island of Chio ‡.

‡ Lib. xviii. c. 7.

18 Its properties.

Starch has a fine white colour, and is usually concreted in longish masses; it has scarcely any smell, and very little taste. When kept dry, it continues for a long time uninjured though exposed to the air.

19 How acted on by water.

Starch does not dissolve in cold water, but very soon falls to powder. It combines with boiling water, and forms with it a thick paste. Linen dipt into this paste, and afterwards dried suddenly, acquires, as is well known, a great degree of stiffness. When this paste is left exposed to damp air it soon loses its consistency, acquires an acid taste, and its surface is covered with mould.

20 Alcohol,

Starch is so far from dissolving in alcohol, even when assisted by heat, that it does not even fall to powder.

21 Acids,

When starch is thrown into any of the mineral acids, at first no apparent change is visible. But if an attempt is made to break the larger pieces while in acids to powder, they resist it, and feel exceedingly tough and adhesive. Sulphuric acid dissolves it slowly, and at the same time a smell of sulphurous acid is emitted, and such a quantity of charcoal is evolved, that the dish containing the mixture may be inverted without spilling any of it. Indeed if the quantity of starch be sufficient, the mixture becomes perfectly solid. The charcoal may be separated by dilution and filtration. In muriatic acid starch dissolves still more slowly. The solution resembles mucilage of gum arabic, and still retains the peculiar odour of muriatic acid. When allowed to stand for some time, the solution gradually separates into two parts; a perfectly transparent straw-coloured liquid below, and a thick, muddy, oily, or rather mucilaginous substance, above. When water is poured in, the muriatic smell instantly disappears, and a strong smell is exhaled, precisely similar to that which is felt in corn-

 mills,

Gluten.

mills. Ammonia occaſions a ſlight precipitate, but too ſmall to be examined.

Nitric acid diſſolves ſtarch more rapidly than the other two acids; it acquires a green colour, and emits nitrous gas. The ſolution is never complete, nor do any cryſtals of oxalic acid appear unleſs heat be applied. In this reſpect ſtarch differs from ſugar, which yields oxalic acid with nitric acid, even at the temperature of the atmoſphere. When heat is applied to the ſolution of ſtarch in nitric acid, both oxalic and malic acid is formed, but the undiſſolved ſubſtance ſtill remains. When ſeparated by filtration, and afterwards edulcorated, this ſubſtance has the appearance of a thick oil, not unlike tallow; but it diſſolves readily in alcohol. When diſtilled, it yields acetous acid, and an oil having the ſmell and the conſiſtence of tallow *.

22 Heat.

When ſtarch is thrown upon a hot iron, it melts, blackens, froths, ſwells, and burns with a bright flame like ſugar, emitting, at the ſame time, a great deal of ſmoke; but it does not explode, nor has it the caromel ſmell which diſtinguiſhes burning ſugar. When diſtilled, it yields water impregnated with an acid, ſuppoſed to be the pyromucous, and mixed with a little empyreumatic oil. The charcoal which remains is eaſily diſſipated when ſet on fire in the open air; a proof that it contains very little earth.

Decompoſition.

Barley grain conſiſts almoſt entirely of ſtarch, not however in a ſtate of perfect purity. In the proceſs of malting, which is nothing elſe than cauſing the barley to begin to vegetate, a great part of the ſtarch is converted into ſugar. During this proceſs oxygen gas is abſorbed, and carbonic acid gas is emitted. Water, too, is abſolutely neceſſary; hence it is probable, that it is decompoſed, and its hydrogen retained †. Starch, then, ſeems to be converted into ſugar by diminiſhing the proportion of its carbon, and encreaſing that of its hydrogen and oxygen. Its diſtillation ſhews us that it contains no other ingredients than theſe three.

Subſtances containing it.

Starch is contained in a great variety of vegetable ſubſtances; moſt commonly in their ſeeds or bulbous roots; but ſometimes alſo in other parts. Mr Parmentier, whoſe experiments have greatly contributed towards an accurate knowledge of ſtarch, has given us the following liſt of the plants from the roots of which it may be extracted.

Arctium lappa,	Imperatoria oſtrutheum,
Atropa belladonna,	Hyoſcyamus niger,
Polygonum biſtorta,	Rumex obtuſifolius,
Bryonia alba,	——— acutus,
Colchicum autumnale,	——— aquaticus,
Spiræa filipendula,	Arum maculatum,
Ranunculus bulboſus,	Orchis maſcula,
Scrophularia nodoſa,	Iris pſeudacorus,
Sambucus ebulus,	—- fœtidiſſima,
———— nigra,	Orobus tuberoſus,
Orchis morio,	Bunium bulbocaſtanum.

It is found alſo nearly pure in the following ſeeds:

Oats,	Cheſnut,	Acorn,
Rice,	Horſecheſnut,	And alſo in
Maiz,	Peas,	Salop,
Millet,	Beans,	Sago.

SECT. III. *Of GLUTEN.*

WHEN wheat flour is waſhed in the manner deſcribed in the laſt ſection, in order to obtain ſtarch from it, the ſubſtance which remains, after every thing has been waſhed away which cold water can ſeparate, is called *gluten*. It was diſcovered by Beccaria an Italian philoſopher, to whom we are indebted for the firſt analyſis of wheat flour †.

25 Gluten, how obtained.

26 Its properties.

Gluten, when thus obtained, is of a grey colour, exceedingly tenacious, ductile, and elaſtic, and may be extended to twenty times its original length. When very thin, it is of a whitiſh colour, and has a good deal of reſemblance to animal tendon or membrane. In this ſtate it adheres very tenaciouſly to other bodies, and has often been uſed to cement together broken pieces of porcelain. Its ſmell is agreeable. It has ſcarce any taſte, and does not loſe its tenacity in the mouth.

27 Action of air.

When expoſed to the air, it gradually dries; and, when completely dry, it is pretty hard, brittle, ſlightly tranſparent, of a dark brown colour, and has ſome reſemblance to *glue*. It breaks like a piece of glaſs, and the edges of the fracture reſemble in ſmoothneſs thoſe of broken glaſs; that is to ſay, it breaks with a *vitreous* fracture.

28 Water.

When expoſed to the air, and kept moiſt, it ſoon putrifies; but when dry, it may be kept any length of time without alteration. It is inſoluble in water; tho' it imbibes and retains a certain quantity of it with great obſtinacy. To this water it owes its elaſticity and tenacity. When boiled in water, it loſes both theſe properties. It is ſoluble in alcohol, as Mr Vauquelin informs us ‡; and precipitated again, as Mr Fourcroy has obſerved, by pouring into the alcohol two parts of water §.

29 Acids.

Gluten is ſoluble in the three mineral acids. When nitric acid is poured on it, and heat applied, a quantity of azotic gas is emitted, as Berthollet ha[illegible] and, by continuing the heat, a quantity of oxalic acid is formed ‖.

30 Alkalies.

Alkalies diſſolve gluten when they are aſſiſted by heat. The ſolution is never perfectly tranſparent. Acids precipitate the gluten from alkalies, but it is deſtitute of its elaſticity ¶.

31 Heat.

When moiſt gluten is ſuddenly dried, it ſwells amazingly. Dry gluten, when expoſed to heat, cracks, ſwells, melts, blackens, exhales a fetid odour, and burns preciſely like feathers or horn. When diſtilled, there comes over water impregnated with ammonia and an empyreumatic oil; the charcoal which remains is with difficulty reduced to aſhes. From theſe phenomena, it is evident that gluten is compoſed of carbon, hydrogen, azot, and oxygen: perhaps alſo it contains a little lime. In what manner theſe ſubſtances are combined is unknown.

32 Its compoſition.

33 Subſtances containing it.

The only vegetable ſubſtance which has been hitherto found to contain it abundantly, is wheat flour. Vauquelin alſo found it in the fruit of the *caſſia fiſtuloris* *, and Fourcroy in the bark of a ſpecies of quinquina from St Domingo †. It probably exiſts in many other plants.

SECT. IV. *Of ALBUMEN.*

Albumen.

IF the water in which wheat flour has been waſhed in order to obtain ſtarch and gluten, according to the directions laid down in the two laſt ſections, be filtrated, and afterwards boiled, a ſubſtance precipitates in white flakes; to which Mr Fourcroy, who firſt pointed it

* *Scheele*, *Crell's Journ.* ii. 14. *Engliſh tranſlation.*

† *Cruikſhank*, *on Diabetes.*

† *Collect. Acad.* x. 1.

‡ *Ann. de Chim.* vi. 178.

§ *Ibid.* viii.

‖ *Vauquelin*, *Ibid.* vi. 275.

¶ *Fourcroy.*

* *Ibid.*

† *Ibid.* viii. 135.

Jelly. it out, has given the name of *albumen* (A), on account of its resemblance to the *white* of an egg ‡.

‡ Ann. de Chim. iii. 255.

It is evident, from the method of obtaining it, that albumen, in its natural state, is soluble in water, and

34 Properties of albumen. that heat precipitates it from that fluid in a concrete state. While dissolved in water, it has scarcely any taste; but it has the property of changing vegetable blues, especially that which is obtained from the flowers of the mallow (*malva sylvestris*), into a green §. When allowed to remain dissolved in water, it putrifies without becoming previously acid ‖.

§ Fourcroy, Ibid. 257.

‖ Ibid.

After it has been precipitated from water in a concrete state by boiling, it is no longer soluble in water as before. Alcohol also precipitates it from water precisely in the same state as when it is precipitated by heat.

When concrete albumen is dried it becomes somewhat transparent, and very like glue. In that state it is soluble in alkalies, especially ammonia *.

* Ibid.

When distilled it gives out carbonat of ammonia, a red fetid oil, and carbonated hydrogen gas; and a spungy charcoal remains behind †. From this, it is evident

35 Its composition. that albumen, like gluten, is composed of carbon, azot, hydrogen, and oxygen; but the proportions and combinations of these substances are altogether unknown.

† Ibid.

Mr Fourcroy found albumen in the expressed juice of scurvy grass, cresses, cabbage, and almost all cruciform plants. He found it, too, in a great many young and succulent plants; but never a particle in those parts of vegetables which contain an acid. He observed also that the quantity decreased constantly with the age of the plant.

SECT. V. Of Jelly.

If we press out the juice of ripe blackberries, currants, and many other fruits, and allow it to remain for some time in a state of rest, it partly coagulates into a tremulous soft substance, well known by the name of *jelly*. If we pour off the uncoagulated part, and wash the coagulum with a small quantity of water, we obtain *jelly* approaching to a state of purity.

Properties of jelly. In this state it is nearly colourless, unless tinged by the peculiar colouring matter of the fruit; it has a pleasant taste, and a tremulous consistency. It is scarcely soluble in cold water, but very soluble in hot water; and, when the solution cools, it again coagulates into the form of a jelly †. When long boiled, it loses the property of gelatinising by cooling, and becomes analagous to mucilage ‡. This is the reason that in making currant jelly, or any other jelly, when the quantity of sugar added is not sufficient to absorb all the watery parts of the fruit, and consequently it is necessary to concentrate the liquid by long boiling, the mixture often loses the property of coagulating, and the jelly, of course, is spoiled §.

† Vauquelin, Ann. de Chim. vi. 82.

‡ Ibid. 100.

§ Ann. de Chim. v. 102.

Jelly combines readily with alkalies; nitric acid converts it into oxalic acid, without separating any azotic gas ‖. When dried it becomes transparent ¶. When distilled it affords a great deal of pyromucous acid, a small quantity of oil, and scarcely any ammonia †.

‖ Ibid. vi. 282.

¶ Ibid. v. 105.

† Ibid. vi. 285.

Jelly exists in all acid fruits, as oranges, lemons, gooseberries, &c. and no albumen is ever found in those parts of vegetables which contain an acid. This circumstance has induced Fourcroy to suppose that jelly is albumen combined with an acid *: but this conjecture has not been verified by experiment; nor indeed is it probable that it ever shall; as albumen evidently contains a quantity of azot, and jelly scarcely any. The products of jelly by distillation shew that it approaches nearer than any other vegetable substance to the nature of sugar.

* Ibid. iii. 254.

SECT. VI. Of Gum.

THERE is a thick transparent tasteless fluid which sometimes exudes from certain species of trees. It is very adhesive, and gradually hardens without losing its transparency; but easily softens again when moistened

37 Gum how obtained. with water. This exsudation is known by the name of *gum*. The gum most commonly used is that which exsudes from different species of the *mimosa*, particularly the *nilotica* †. It is known by the name of *gum arabic*. Gum likewise exsudes abundantly from the *prunus avium*, or common wild cherry tree of this country.

† Salisbury, Phil. Mag. v. 241.

Gum is usually obtained in small pieces like tears, moderately hard, and somewhat brittle while cold, so that it can be reduced by pounding to a fine powder. Its colour is usually yellowish, and it is not destitute of lustre. It has no smell; its taste is insipid.

Gum undergoes no change from being exposed to the atmosphere; but the light of the sun makes it as-

38 Action of water. sume a white colour. Water dissolves it in large quantities. The solution which is known by the name of *mucilage* (B), is thick and adhesive: it is often used as a paste, and to give stiffness and lustre to linen. When spread out thin it soon dries, and has the appearance of a varnish; but it readily attracts moisture, and becomes glutinous. Water washes it away entirely. When mucilage is evaporated the gum is obtained unaltered.

39 Action of alcohol. Gum is insoluble in alcohol. When alcohol is poured into mucilage, the gum immediately precipitates; because the affinity between water and alcohol is greater than that between water and gum.

The action of alkalies and earths upon gum has not been

(A) The existence of albumen in vegetables was known to Scheele. He mentions it particularly in his paper on Milk, first published in the year 1780. See *Scheele's Works*, II. 55. Dijon edition.

(B) Hermstadt uses this word in a different sense. He makes a distinction between *gum* and *mucilage*. The solution of *gum* in water is transparent and glutinous, and can be drawn out into threads; whereas that of *mucilage* is opake, does not feel glutinous, but slippery, and cannot be drawn into threads. Gum may be separated from mucilage by the following process:

Let the gum which is supposed to be mixed with mucilage, previously reduced to a dry mass, be dissolved in as small a quantity of water as possible, and into the solution drop at intervals diluted sulphuric acid. The mucilage coagulates while the gum remains dissolved. When no more coagulation takes place, let the mixture remain at rest for some time, and the mucilage will precipitate to the bottom, and assume the consistence of jelly. Decant off the liquid part, and evaporate the mucilage to dryness by a gentle heat till it acquires the consistence of horn. *Med. and Phys. Jour.* iii. 370.

Extract. been examined. Acids do not precipitate it from mucilage ‡. The concentrated mineral acids destroy it.
‡ Vauquelin. Concentrated sulphuric acid decomposes it; water is formed, and perhaps also acetous acid; while charcoal is precipitated. Nitric acid converts it into oxalic acid; oxy muriatic acid, on the contrary, into citric acid *.

* Id. Ann de Chim vi 178. When gum is exposed to heat it softens and swells, but does not melt; it emits air bubbles, blackens, and at last, when nearly reduced to charcoal, emits a low
Of heat. blue flame. This flame appears sooner if a flaming substance be held just above the gum. After the gum is consumed, there remains a small quantity of white ashes, composed chiefly of the carbonats of lime and potass.

When gum is distilled in a retort, the products are water impregnated with a considerable quantity of pyromucous acid, a little empyreumatic oil, carbonic acid gas, and carbonated hydrogen gas. When the pyromucous acid obtained by this process is saturated with lime, a quantity of ammonia is disengaged with which that acid had been combined. The charcoal which remained in the retort leaves behind it, after incineration,
§ Cruick-shank Rollo on D. Iter a little lime, and phosphat of lime §

These experiments shew us that gum is composed of
41 Compo- hydrogen, carbon, oxygen, azot, lime, and phosphorus; but the proportions and combinations of these substances are unknown to us. Mr Cruickshank has rendered it probable that the quantity of carbon is greater, and
‖ Ibid. the quantity of oxygen less, in gum than in sugar ‖.

Gum, or mucilage, exists most abundantly in young plants, and gradually disappears as they arrive at perfection. It forms a great proportion of the leaves and roots of many eatable plants.

Sect. VII. *Of Extract.*

The word *extract* was at first applied to all those substances which were extracted from plants by means of water, and consequently included gum, jelly, and several other bodies. But of late it has been confined, by those chemists who have paid attention to the use of
42 Extract, how obtained. language, to a substance which exists in many plants, and which may be obtained by infusing *saffron* in water for some time, filtrating the infusion, and evaporating it to dryness. The residuum, after evaporation, is *extract* nearly pure ¶. It possesses the following properties:
¶ Hermbstadt.

43 Its properties. Water dissolves it in considerable quantities, especially hot water. Alcohol also dissolves it with facility. This property of being soluble both in water and alcohol has induced some chemists to give *extract* the name of *soap*. It is insoluble in sulphuric ether. These three properties are sufficient to distinguish it from every other vegetable substance *.
* Hermbstadt.

When the solution of extract in water is exposed for some time in the open air, the extract precipitates, and is now no longer soluble in water. This change is supposed to proceed from the addition of a quantity of
† Fourcroy. oxygen which it imbibes from the atmosphere †.

When oxy-muriatic acid is poured into a watery solution of extract, that substance precipitates in yellow flakes. These flakes are insoluble in water; they are insoluble also in alcohol at the temperature of 97°; but that liquid dissolves them at the temperature of 120°. They are soluble also in alkalies, and in boiling-hot
‡ Fourcroy. water they melt into a yellow mass ‡.

Extract is soluble in acids. Heat softens but does not melt it §. Tan.

It is found in a great variety of plants; but as no method of obtaining it perfectly pure has hitherto been discovered, the extracts of different plants differ somewhat from each other both in their colour and smell. § Id. Ann de Chim. viii.

Sect. VIII. *Of Tan.*

If a quantity of nut galls, coarsely powdered, be kept for some time infused in cold water, if the water be filtered, and a solution of muriat of tin be dropt into it, a copious white precipitate falls to the bottom. 44 Preparation of tan
This precipitate is to be carefully washed and diffused (for it will not dissolve) thro' a large quantity of water, and this water is to be saturated with sulphurated hydrogen gas so completely that it will not absorb any more. By this treatment the white precipitate will gradually disappear, and a brown precipitate will take its place. This brown precipitate must be separated by filtration; and the water, which has now acquired the colour and the taste of the infusion of nut galls, must be evaporated to dryness. A substance remains behind, known by the name of *tan* or *tannine*.

It was first discovered by Seguin, who pointed out some of its properties, and the method of detecting it in plants ‖. The above method of obtaining it in a state of purity was contrived by Mr Proust. Tan exists in the solution of nut galls combined with gallic acid. ‖ Nicholson's Jour. i. 271.
The oxyd of tin has a strong affinity for it. When muriat of tin is poured in, the tan combines with the oxyd, and the compound, being insoluble, falls to the bottom. Sulphur has a stronger affinity for the oxyd than tan has. Hence when sulphurated hydrogen gas is thrown upon this compound, the sulphur leaves the gas and combines with the tin; and the compound, being insoluble, falls to the bottom. The hydrogen gas escapes, and nothing remains in the water except tan.

Tan is a brittle substance, of a brown colour. It breaks with a vitreous fracture, and does not attract moisture from the air. Its taste is exceedingly astringent. It is very soluble in water. The solution is of a deep brown colour, a very astringent and bitter taste, and has the odour which distinguishes a solution of nut galls. It froths when agitated, like a solution of soap; but does not feel unctuous. Acids precipitate the tan from this solution. 45 Its properties.

Tan is still more soluble in alcohol than in water.

When the solution of tan is poured into a solution of the brown sulphat of iron, a deep blue coloured precipitate immediately appears, consisting of the tan combined with the oxyd. This precipitate, when dried, assumes a black colour. It is decomposed by acids. The green sulphat of iron is not altered by tan.

When too great a proportion of brown sulphat of iron is poured into a solution of tan, the sulphuric acid, set at liberty by the combination of the iron and tan, is sufficient to redissolve the precipitate as it appears; but the precipitate may easily be obtained by cautiously saturating this excess of acid with potass. When the experiment is performed in this manner, all the red sulphat of iron which remains in the solution undecomposed is converted into green sulphat. Mr Proust, to whom we are indebted for almost every thing yet known concerning the properties of tan, supposes that this change is produced

Camphor. produced by the tan abforbing oxygen from the iron. This may very poffibly be the cafe; but his experiments are infufficient to prove that it is. The fame change takes place if red oxyd be mixed with a confiderable excefs of fulphuric acid, and diluted with water.

Tan combines readily with oxygen. When oxy muriatic acid is poured upon it, its colour deepens, and it lofes all its peculiar characters *.

* Prouft, Ann. de Chim. xxv. 225.

Tan exifts in almoft all thofe vegetable fubftances which have an aftringent tafte. It is almoft conftantly combined with gallic acid. The following table, drawn

46 Plants containing it up by Mr Biggin †, though the rule which the author followed in making his experiments precluded rigid accuracy, will ferve to give fome idea of the proportions of tan which exift in different plants:

† Phil. Tranf. 1799.

SECT. IX. Of Oils.

There are two [illegible] of oils; namely, *fixed* and *volatile*, both of which are found abundantly in plants.

1. Fixed oil is found in the feeds of many plants, efpecially of the olive, beech, flax, almond, rape, &c.

2. Volatile oil is obtained by diftillation from the leaves, flowers, or roots of aromatic plants, as lavender, [illegible].

As an account of the properties of oils has been given already in the article CHEMISTRY, *Suppl.* it would be fuperfluous to repeat it here.

SECT. X. Of Camphor.

The laurus camphora is a tree which grows in China, Japan, and feveral parts of India. When the roots of this tree are put into an [illegible] furnifhed with a capital, and a [illegible] heat [illegible] a particular fubftance fublimes [illegible] known by the name of *camphor*. The Dutch afterwards purify this camphor by a fecond fublimation.

Camphor is a white brittle fubftance, having a peculiar aromatic odour and a ftrong tafte.

47 Properties of camphor. It is not altered by atmofpheric air; but it is fo volatile, that if it be expofed during warm weather in an open veffel, it evaporates completely. When fublimed in clofe veffels it cryftallifes in hexagonal plates or pyramids *.

* Romieu.

It is infoluble in water; but it communicates to that liquid a certain portion of its peculiar odour.

It diffolves readily in alcohol, and is precipitated again by water. If the alcohol be diluted with water as much as poffible, without caufing the camphor to precipitate, fmall cryftals of camphor refembling feathers gradually form †.

† Romieu, Mem. Par. 1756, p. 41.

Camphor is foluble alfo in hot oils, both fixed and volatile; but as the folution cools the camphor precipitates, and affumes the form of plumofe, or feather-like cryftals ‡.

‡ Romieu, Mem. Par. 1756, p. 41.

Camphor is not acted on by alkalies, either pure or in the ftate of carbonats. Pure alkalies indeed feem to diffolve a little camphor; but the quantity is too fmall to be perceptible by any other quality than its odour §. Neither is it acted upon by any of the neutral falts which have hitherto been tried.

§ Bouillon la Grange, Ann. de Chim. xxiii. 154.

Acids diffolve camphor, but it is precipitated again, unaltered, by alkalies, and even by water. The folution of camphor in fulphuric acid is red; that in the nitric acid is yellow. This laft folution has obtained the abfurd name of *oil of camphor*. When nitric acid is diftilled repeatedly off camphor, it converts it into camphoric acid.

Muriatic, fulphurous, and fluoric acids, in the ftate of gas, diffolve camphor. When water is added, the camphor appears unaltered in flakes, which fwim on the furface of the water §.

§ Fourcroy.

When heat is applied to camphor it is volatilized. If the heat be fudden and ftrong, the camphor melts before it evaporates. It catches flame very readily, and emits a great deal of fmoke as it burns, but it leaves no refiduum. It is fo inflammable that it continues to burn even on the furface of water. When camphor is fet on fire in a large glafs globe filled with oxygen gas, and containing a little water, it burns with a very bright flame, and produces a great deal of heat. The inner furface of the glafs is foon covered with a black powder, which has all the properties of charcoal, a quantity of carbonic acid gas is evolved, the water in the globe acquires a ftrong fmell, and is impregnated with carbonic acid and camphoric acid ||.

If two parts of alumina and one of camphor be formed into a pafte with water, and diftilled in a glafs retort, there comes over into the receiver (which fhould contain a little water, and communicate with a pneumatic apparatus) a volatile oil of a golden yellow colour, a little camphoric acid which diffolves in the water, and a quantity of carbonic acid gas, and carbonated hydrogen gas, which may be collected by means of a pneumatic apparatus. There remains in the retort a fubftance of a deep black colour, compofed of alumina and charcoal. By this procefs, from 122.284 parts of camphor, Mr Bouillon la Grange, to whom we are indebted for the whole of the analyfis of camphor, obtained 45.856 parts of volatile oil, and 30.571 parts of charcoal. The proportion of the other products was not afcertained *. 48 Its analyfis.

|| Bouillon la Grange, ibid. p. 168.

* Ibid. p. 157.

From this analyfis, Mr Bouillon la Grange concludes, that camphor is compofed of volatile oil, and charcoal or carbon, combined together. We learn, from his experiments, that the ultimate ingredients of camphor are carbon and hydrogen; and that the proportion of carbon is much greater than in oils.

Camphor exifts in a great many plants. Neumann, Geoffroy, and Cartheufer, extracted it from the roots of zedoary, thyme, fage, &c. and rendered it probable that it is contained in almoft all the labiated plants. It has been fuppofed to exift in thefe plants combined with volatile oil. Prouft has fhewn how it may be extracted, in confiderable quantity, from many volatile oils †. 49 Plants containing it.

† Ann. de Chim. xxxi. 179.

Camphor, which was unknown to the ancient Greeks and Romans, was introduced into Europe by the Arabians.

Reſins.

bans. Æt[illegible] is the firſt perſon who mentions it. It ſeems, however, to have been very early known to the eaſtern nations.

It is much uſed in medicine. It is a powerful ſtimulant; it is conſidered as peculiarly efficacious in diſeaſes of the urinary organs; it is often ſerviceable in [illegible], and procures ſleep when every other medicine fails.

SECT. XI. *Of Resins.*

There is a yellowiſh white coloured ſubſtance which often exſudes from the *Abies Montana*, or *common Scotch fir*, and likewiſe from other fir trees. It is ſomewhat tranſparent, is hard and brittle, of a diſagreeable taſte, and may be collected in conſiderable quantities. This ſubſtance is known by the name of *reſin*; and the ſame name is alſo applied to all ſubſtances which poſſeſs nearly the ſame properties with it. Reſin may be diſtinguiſhed from every other ſubſtance by the following properties:

50 Properties of reſin.

It is more or leſs concrete, and has an acrid and hot taſte.

It is totally inſoluble in water. By this property it may eaſily be ſeparated from gum, if they happen to be mixed together.

It is ſoluble in alcohol, and in ſulphuric ether *. By the firſt of theſe properties we may ſeparate it from gum, and by the laſt from extract; for extract is inſoluble in ſulphuric ether. When theſe ſolutions are evaporated the reſin is obtained unaltered. If the ſolution be ſpread thin upon any body, it ſoon dries by the evaporation of the alcohol; the reſin remains behind, and covers the body with a ſmooth ſhining tranſparent coat, which cannot be waſhed off by water. This proceſs is called *varniſhing*.

* Ib.

Reſin is ſoluble alſo in volatile oils; and theſe ſolutions are often uſed likewiſe in varniſhing.

Reſin is ſcarcely acted upon by acids. Alkalies combine with it, but the combination is not eaſily effected.

When reſin is heated it readily melts; and if the heat be increaſed it is volatilized, and burns with a white flame and ſtrong ſmell. When diſtilled it yields much volatile oil, but ſcarcely any acid.

When volatile oils are expoſed for ſome time to the action of the atmoſphere they acquire conſiſtency, and aſſume the properties of reſins. During this change they abſorb a quantity of oxygen from the air. Weſtrum put 30 grains of oil of turpentine into 40 cubic inches of oxy-muriatic acid gas. Heat was evolved, the oil gradually evaporated, and aſſumed the form of yellow reſin †. Theſe facts render it probable that reſin is merely volatile oil combined with a quantity of oxygen.

† Crell Annals 1790.

To know whether any vegetable ſubſtance contains reſin, we have only to pour ſome ſulphuric ether upon it in powder, and expoſe the infuſion to the light. If any reſin be preſent the ether will aſſume a brown colour ‡.

‡ Hermſtadt.

51 Number of reſins.

The number of reſins is conſiderable. They differ from each other chiefly in colour, taſte, ſmell, and conſiſtency. Whether theſe reſins be really different combinations, or, as is moſt likely, owe theſe differences to foreign ingredients, either combined with the reſin, or mechanically mixed with it, is not at preſent known. To deſcribe each reſin ſeparately would be to little purpoſe, as ſcarcely any thing is known of them except their general properties as reſins. The following is a liſt of the principal. The reader will find an account of the manner of obtaining them, and of their uſes, by conſulting the name of each in the *Encyclopædia*.

1. Common reſin,	7. Sandarac,
2. Turpentine,	8. Guaiacum,
3. Pitch,	9. Labdanum,
4. Galipot,	10. Dragon's blood,
5. Elemi,	11. Copaiba.
6. Maſtic,	

52 Balſams.

There are three vegetable ſubſtances which have been denominated *balſams* by ſome of the later French writers. They appear to conſiſt of reſin, or volatile oil combined with benzoic acid. Theſe ſubſtances are, benzoin, balſam of Tolu, and ſtorax. For an account of them we refer to the *Encyclopædia*.

53 Gum reſins.

Many vegetable ſubſtances occur in medicine which conſiſt chiefly of a mixture of gum and reſin. Theſe ſubſtances, of courſe, have a number of the properties both of gums and reſins. For this reaſon they have been denominated *gum reſins*. The following are the moſt important of theſe ſubſtances:

Olibanum,	Aloes,
Galbanum,	Myrrh,
Scammony,	Ammoniac,
Aſafœtida,	Opium.

For an account of them we refer to the *Encyclopædia*.

SECT. XII. *Of Caoutchouc.*

54 Diſcovery of caoutchouc.

About the beginning of the 18th century a ſubſtance, called *caoutchouc*, was brought as a curioſity from America. It was ſoft, wonderfully elaſtic, and very combuſtible. The pieces of it that came to Europe were uſually in the ſhape of bottles, birds, &c. This ſubſtance is very much uſed in rubbing out the marks made upon paper by a black lead pencil; and therefore in this country it is often called *Indian rubber*. Nothing was known of its production, except that it was obtained from a tree, till the French academicians went to South America in 1735 to meaſure a degree of the meridian. Mr de la Condamine ſent an account of it to the French Academy in the year 1736. He told them, that there grew in the province of Eſmeraldas, in Braſil, a tree, called by the natives *Hhevé*; that from this tree there flowed a milky juice, which, when inſpiſſated, was *caoutchouc*. Don Pedro Maldonado, who accompanied the French academicians, found the ſame tree on the banks of the Maragnon; but he died ſoon after, and his papers were never publiſhed. Mr Freſnau, after a very laborious ſearch, diſcovered the ſame tree in Cayenne. His account of it was read to the French Academy in 1751.

55 Plants containing it.

It is now known that there are at leaſt two trees in South America from which caoutchouc may be obtained, the Hævea Caoutchouc and the Jatropha Elaſtica; and it is exceedingly probable that it is extracted alſo from other ſpecies of Hævea and Jatropha. Several trees likewiſe which grow in the Eaſt Indies yield caoutchouc; the principal of theſe are, the Ficus Indica, the Artocarpus Integrifolia, and the Urceola Elaſtica; a plant diſcovered by Mr Howiſon, and firſt deſcribed and named by Dr Roxburgh *.

* Aſiatic Reſearches, v. 167. London edition.

Caoutchouc When any of these plants is punctured, there exsudes from it a milky juice, which, when exposed to the air, gradually lets fall a concrete substance, which is caoutchouc.

If oxy-muriatic acid be poured into the milky juice, the caoutchouc precipitates immediately, and, at the same time, the acid loses its peculiar odour. This renders it probable that the formation of the caoutchouc is owing to its basis absorbing oxygen *. If the milky juice be confined in a glass vessel containing common air, it gradually absorbs oxygen, and a pellicle of caoutchouc appears on its surface †.

* Fourcroy, Ann. de Chim. xi. 219.
† Ibid.

56 Properties of caoutchouc. Caoutchouc was no sooner known than it drew the attention of philosophers. Its singular properties promised that it would be exceedingly useful in the arts, provided any method could be fallen upon to mould it into the various instruments for which it seemed peculiarly adapted. Messrs de la Condimine and Fresnau had mentioned some of its properties; but Macquer was the first person who undertook to examine it with attention. His experiments were published in the memoirs of the French Academy for the year 1768. They threw a good deal of light on the subject; but Macquer fell into some mistakes, which were pointed out by Mr Berniard, who published an admirable paper on caoutchouc in the 17th volume of the *Journal de Physique*. To this paper we are indebted for the greater number of facts at present known respecting caoutchouc. Mr Groffart and Mr Fourcroy have likewise added considerably to our knowledge of this singular substance; both of their treatises have been published in the 11th volume of the *Annales de Chimie*.

Caoutchouc, when pure, is of a white colour (c), and without either taste or smell ‡. The blackish colour of the caoutchouc of commerce is owing to the method [illegible] it after it has been spread upon moulds. The usual way is to spread a thin coat of the milky juice upon the mould, and then to dry it by exposing it to smoke; afterwards another coat is spread on, which is dried in the same way. Thus the caoutchouc of commerce consists of numerous layers of pure caoutchouc alternating with as many layers of soot.

‡ Fourcroy, ibid. 232.

Caoutchouc is soft and pliable like leather. It is exceedingly elastic and adhesive; so that it may be forcibly stretched out much beyond its usual length, and instantly recover its former bulk when the force is withdrawn. It cannot be broken without very considerable force.

57 Action of water, It is not altered by exposure to the air; it is perfectly insoluble in water; but if boiled for some time its edges become somewhat transparent, owing undoubtedly to the water carrying off the soot; and so soft, that when two of them are pressed and kept together for some time, they adhere as closely as if they formed one piece. By this contrivance pieces of caoutchouc may be soldered together, and thus made to assume whatever shape we please §.

§ Groffart, Ann. de Chim. xi. 153.

58 Alcohol, Caoutchouc is insoluble in alcohol. This property was discovered very early, and fully confirmed by the experiments of Mr Macquer. The alcohol, however, renders it colourless.

59 Ether, Caoutchouc is soluble in ether. This property was first pointed out by Macquer. Berniard, on the contrary, found that caoutchouc was scarcely soluble at all in sulphuric ether, which was the ether used by Macquer, and that even nitric ether was but an imperfect solvent. The difference in the results of these two chemists was very singular; both were remarkable for their accuracy, and both were too well acquainted with the subject to be easily misled. The matter was first cleared up by Mr Cavallo. He found that ether, when newly prepared, seldom or never dissolved caoutchouc completely; but if the precaution was taken to wash the ether previously in water, it afterwards dissolved caoutchouc with facility. Mr Groffart tried this experiment, and found it accurate ||. It is evident from this that these chemists had employed ether in different states. The washing of ether has two effects. It deprives it of a little acid with which it is often impregnated, and it adds to it about one-tenth of water, which remains combined with it.

|| Ann. de Chim. xi. 147.

When the ether is evaporated, the caoutchouc is obtained unaltered. Caoutchouc, therefore, dissolved in ether, may be employed to make instruments of different kinds, just as the milky juice of the hævea; but this method would be a great deal too expensive for common use.

60 Oils, Caoutchouc is soluble in volatile oils *; but, in general, when these oils are evaporated, it remains somewhat glutinous, and therefore is scarcely proper for those uses to which, before its solution, it was so admirably adapted.

* Berniard.

61 Acids and alkalies, It is insoluble in alkalies †. The acids act upon it with more or less violence according to their nature. Sulphuric acid decomposes it completely, charcoal precipitates, and part of the acid is converted into sulphurous acid. Nitric acid converts it into a yellow substance, analogous to suberic acid. Muriatic acid does not affect it ‡. The other acids have not been tried.

† Id.
‡ Id.

Fabroni has discovered, that rectified petroleum dissolves it, and leaves it unaltered when evaporated ¶.

¶ Ibid. 195. and xii. 156.

62 Heat. When exposed to heat it readily melts; but it never afterwards recovers its properties, but continues always of the consistence of tar. It burns very readily with a bright white flame, and diffuses a fetid odour. In those countries where it is produced, it is often used by way of candle.

When distilled, it gives out ammonia §. It is evident from this, and from the effect of sulphuric and nitric acid upon it, that it is composed of carbon, hydrogen, azot, and oxygen; but the manner in which they are combined is unknown.

§ Fourcroy, Ann. de Chim. xi. 232.

When treated with nitric acid, there came over azotic gas, carbonic acid gas, prussic acid gas; and oxalic acid was formed ||.

|| Ibid.

63 How to separate it from plants. It seems to exist in a great variety of plants; but is usually confounded with the other ingredients. It may be separated from resins by means of alcohol. It may be extracted from the different species of *misseltoe* by water, with which, in the fluid state in which it exists in these plants, it readily combines. When mixed with gum or extract, it may be separated by the following process: Digest a part of the plant containing it first in water and then in alcohol, till all the substances soluble

(c) Mr De Fourcroy says, that blackish brown is the natural colour of caoutchouc. But we have seen some pieces of it from the East Indies, which had been allowed to inspissate in the open air: They were white, with a slight cast of yellow, and had very much the appearance and feel of white soap.

Wax

luble in these liquids be extracted. Dry the residuum, and digest it in five times its weight of rectified petroleum. Express the liquid part by squeezing the substance in a linen cloth. Let this liquid remain several days to settle, then decant off the clear liquid part, mix it with a third part of water and distil, the caoutchouc remains behind *.

* Hermstadt, Med. Phys. Jo iii. 372.

SECT. XIII. *Of Wax.*

THE upper surface of the leaves of many trees is covered with a varnish of wax. This varnish may be separated and obtained in a state of purity by the following process.

64
Wax a vegetable production.

Digest the bruised leaves, first in water and then in alcohol, till every part of them which is soluble in these liquids be extracted. Then mix the residuum with six times its weight of a solution of pure ammonia, and, after sufficient maceration, decant off the solution, filter it, and drop into it, while it is incessantly stirred, diluted sulphuric acid, till more be added than is sufficient to saturate the alkali. The wax precipitates in the form of a yellow powder. It should be carefully washed with water, and then melted over a gentle fire †.

† Ib. ibid. 373.

Mr Tingry first discovered that this varnish possessed all the properties of *bees wax* ‡. Wax then is a vegetable product. The bees extract it unaltered from the leaves of trees and other vegetable substances which contain it. They seem, however, to mix it with some of the pollen of flowers.

‡ Enc. Meth. Forets et Bois, i. 100.

65
Its properties.

Wax, when pure, is of a whitish colour, it is destitute of taste, and has scarcely any smell. Bees wax indeed has a pretty strong aromatic smell; but this seems chiefly owing to some substance with which it is mixed; for it disappears almost completely by exposing the wax, drawn out into thin ribands, for some time to the atmosphere. By this process also, which is called *bleaching*, the yellow colour of the wax disappears, and it becomes very white. Bleached wax is not affected by the air §.

§ Senebier, Ann. de Chim, xii. 60 and Jour. de Phys. xxxviii. 56.

Wax is insoluble in water and in alcohol. It combines readily with alkalies, and forms with them a soap which is soluble in water ‖.

‖ Chaptal, iii 164.

Punic wax, which the ancients employed in painting in encausto, is a soap composed of twenty parts of wax and one of soda *. Its composition was ascertained by Mr Lorgna †.

* Plin l. 21. c. 14.
† Jour. de Phys. Nov. 1785.

Sulphuric and nitric acids decompose wax completely; oxy-muriatic acid bleaches it instantaneously.

Wax combines readily with oils, and forms with them a substance of greater or less consistency according to the quantity of oil. This composition, which is known by the name of *cerate*, is much employed by surgeons.

When heat is applied to wax it becomes soft; and at the temperature of 142°, if unbleached, or of 155° if bleached ‡, it melts into a colourless transparent fluid, which concretes again, and resumes its former appearance as the temperature diminishes. If the heat be still farther increased, the wax boils and evaporates; and if a red heat be applied to the vapour, it takes fire and burns with a bright flame. It is this property which renders wax so useful for making candles.

‡ Nicholson's Journal, i. 71.

66
Analysis.

Mr Lavoisier, by means of the apparatus described in the article CHEMISTRY, *Suppl.* n° 353. contrived to burn wax in oxygen gas. The quantity of wax consumed was 21.9 grains. The oxygen gas employed in consuming that quantity amounted to 66.55 grains. Consequently the substances consumed amounted to 88.45 grains. After the combustion, there were found in the glass vessel 62.58 grains of carbonic acid, and a quantity of water, which was supposed to amount to 25.87 grains. These were the only products.

Woody Fibre.

Now 62.58 grains of carbonic acid gas contain

44.50 of oxy and 18.02 of carb; and 25.87 gr of water contain
21.99 of oxy and 3.88 of hydro.

66.55	21.9?

Consequently 21.9 parts of wax are composed of 18.02 of carbon, and 3.88 of hydrogen. And 100 parts of wax are composed of

82.28 carbon,
17.72 hydrogen,

100.00 *.

* Lavoisier, Jour de Phys. xxxi. 59.

If wax be distilled with a heat greater than 212°, there comes over a little water, some sebacic acid, a little very fluid and odorous oil: the oil, as the distillation advances, becomes thicker and thicker, till at last it is of the consistency of butter, and for this reason has been called *butter of wax*. There remains in the retort a small quantity of coal, which is not easily reduced to ashes. When the butter of wax is repeatedly distilled it becomes very fluid, and assumes the properties of volatile oil †.

† Lemery, Mem. Par. 1708, p. 33.

SECT. XIV. *Of the Woody Fibre.*

ALL trees, and most other plants, contain a particular substance, well known by the name of *wood*. If a piece of wood be well dried, and digested, first in a sufficient quantity of water, and then of alcohol, to extract from it all the substances soluble in these liquids, there remains behind only the *woody fibre*.

67
Properties of wood.

This substance, which constitutes the basis of wood, is composed of longitudinal fibres, easily subdivided into a number of smaller fibres. It is somewhat transparent; is perfectly tasteless; has no smell; and is not altered by exposure to the atmosphere.

It is insoluble in water and in alcohol; but soluble in alkalies. The mineral acids decompose it. When distilled it yields, in all probability, pyrolignous acid. When burnt with a smothered fire it leaves behind it a considerable quantity of charcoal.

It is precipitated from alkalies unaltered by acids *.

* Fourcroy, Ann. de Chim. viii. 149.

68
Its analysis.

By nitric acid Fourcroy converted the residuum of quinquina, which does not seem to differ from the woody fibre, into oxalic acid; at the same time there was a little citric acid formed, and a very small quantity of malic and acetous acids. Some azotic gas also was disengaged. By this process he obtained from 100 parts of woody fibre

56.250	oxalic acid,
3.905	citric acid,
0.388	malic acid,
0.486	acetous acid,
0.867	azotic gas,
8.330	carbonat of lime,
70.226	
32.031	residuum.
102.257	

There was likewise a quantity of carbonic acid gas disengaged, the weight of which was unknown. This

increase

Acids.

increase of weight in the product was evidently owing to the oxygen derived from the nitric acid *.

* Ann. de Chim. viii. 152.

When distilled in a retort, 100 parts yield the following products:

26.62	of a yellow liquid, containing alcohol, and acid which had the smell of pyromucous.
6.977	of concrete oil, mostly soluble in alcohol.
22.995	charcoal } in the retort.
3.567	carbonat of lime } in the retort.
60.159	
39.841	gas, half carbonic acid, half carbonated hydrogen.
100.000 *	

* Ibid. 151.

These facts shew us, that the woody fibre is composed of oxygen, carbon, hydrogen, azot, and lime. Mr Chaptal supposes that mucilage differs from woody fibre merely in containing less oxygen. We are certain at least that mucilage or gum is composed of the same ingredients; and Mr Chaptal has shewn, that the juices of plants are partly converted into woody fibre by oxy-muriatic acid, which imparts to them oxygen †. These juices contain both gum and resin; after the formation of the woody fibre the resin is still unaltered. This gives a good deal of probability to his opinion.

† Ibid. xxi. 285.

SECT. XV. *Of Acids.*

THE acids found ready formed in vegetables are the following:

1. Oxalic,	5. Gallic,
2. Tartarous,	6. Benzoic,
3. Citric,	7. Phosphoric.
4. Malic,	

Sometimes also the sulphuric, nitric, and muriatic [illegible] vegetables, combined with alkalies or [illegible] except in very minute quantities.

69 Plants containing [illegible] acid,

1. [illegible] easily detected and distinguished by [illegible] It decomposes all calcareous [illegible] with lime a salt [illegible] water. It [illegible] prisms. It [illegible] by heat.

Oxalic acid [illegible] in vegetables by Mr Scheele. It has [illegible] plants:

The leaves of [illegible]

[illegible]

The root of [illegible]

The leaves of the geranium [illegible]

* Scheele, Crell's Jour. [illegible]. 107. Eng. Transl.
† Ibid. 34.
‡ Hermstadt.

70 Tartarous acid,

2. Tartarous acid is known by the following properties: When a little potass is cautiously dropt into a solution containing it, common tartar is formed, and precipitates to the bottom. Tartarous acid does not decompose the sulphat, nitrat, or muriat of lime. Tartrite of lime is soluble in water. Tartarous acid crystallizes. Its crystals are long slender prisms. It is destroyed by heat.

Tartarous acid has been found in the following vegetable substances:

The pulp of the tamarind *.
The juice of grapes.
 Mulberries †.
 Rumex acetosa, *sorrel* †.
 Rhus coriaria, *sumach* †.
 Rheum rhaponticum ‖.
 Agave Americana ¶.
The roots of triticum repens †.
 Leontodon taraxicum †.

* Vauquelin, Ann. de Chim. v. 92.
† Hermstadt on Veget. Acids.
‖ Bindheim, Crell, 1788, St. 7. s. 42.
¶ Hoffman of Weimar.
† Hermstadt on Veget. Acids.

71 Citric acid,

3. Citric acid is distinguished by the following properties: It does not form tartar when potass is added to it. With lime it forms a salt insoluble in water, which is decomposed by sulphuric, nitric, and muriatic acids. It readily crystallizes. It is destroyed by heat.

Citric acid has been found unmixed with other acids in the following vegetable substances *:

The juice of oranges and lemons.
The berries of vaccinium oxycoccos, *cranberry*.
 ——— vitis idæa, *red whortle berry*.
 Prunus padus, *birdcherry*.
 Solanum dulcamara, *nightshade*.
 Rosa canina, *hip*.

* Scheele, Crell's Jour. ii. 8. Eng. Transl.

It occurs mixed with other acids in many other fruits.

72 Malic acid,

4. Malic acid is known by the following properties: It forms with lime a salt soluble in water, which is decomposed by citric acid. It does not form tartar with potass. It is incrystallizable. Heat destroys it.

Malic acid has been found, by Scheele †, in the fruits of the following plants, which contain no other acid:

Apples.
Berberis vulgaris, *barberry*.
Prunus domestica, *plum*.
——— spinosa, *sloe*.
Sambucus nigra, *elder*.
Sorbus aucuparia, *roan* or *service*.

† Ibid.

73 Malic and citric,

In the following fruits he found nearly an equal quantity of malic and citric acids ‡.

Ribes grossularia, *gooseberry*.
——— rubrum, *currants*.
Vaccinium myrtillus, *bleaberry*.
Crategus aria, *beam*.
Prunus cerasus, *cherry*.
Fragaria vesca, *strawberry*.
Rubus chamæmorus, *cloudberries*, *evrocks*.
——— idæus, *raspberry*.

‡ Ibid.

Malic acid has also been found in the agave americana §, and in the pulp of tamarinds ‖. In the first of these it is mixed with tartarous acid; in the second with tartarous and citric acids.

§ Hoffman of Weimar.
‖ Vauquelin, Ann. de Chim. v. 92.

74 Gallic acid,

5. Gallic acid is known by the following properties: With the brown oxyd of iron it produces a black colour. It is crystallizable. Heat destroys it. It has been found in a great number of plants, chiefly in the bark.—The following table, drawn up by Mr Biggin *, will serve to shew the relative proportions of this acid in different plants:

Elm	7	Sallow	8
Oak cut in winter	8	Mountain ash	8
Horse chesnut	6	Poplar	8
Beech	7	Hazel	9
Willow (boughs)	8	Ash	10
Elder	4	Spanish chesnut	10
Plum tree	8	Smooth oak	10
Willow (trunk)	9	Oak cut in spring	10
Sycamore	6	Huntingdon or Leicester willow	10
Birch	4		
Cherry tree	8	Sumach	14

* Nicholson's Journal, iii. 394.

75 Benzoic acid,

6. Benzoic acid is distinguished by its aromatic odour, and its volatility on the application of a very moderate heat. It has been found hitherto only in three vegetable substances, to which the French chemists have confined the term *balsam*. These three are, *benzoin*, *balsam of tolu*, and *storax*. In these substances it seems to be combined with a resin, or something which has nearly the properties of a resin.

 7. Phos-

7. Phosphoric acid is easily distinguished from the former six, for it is very fixed, and a violent heat does not destroy it as it does the others.

Phosphoric acid has been found in different plants, but only in very small quantities; it is almost constantly combined with lime. Meyer found it in the leaves of many trees*; Thuren found phosphat of lime in the Aconitus Napellus †; and Bergmann found it in all kinds of grain ‡.

* Enc. Meth. Physiol. Veget. i. 100.
† Ann. de Chim. ii. 308.
‡ Bergman, v. 96.

SECT. XVI. *Of ALKALIES.*

THE only alkalies found in plants are potass and soda. Ammonia may indeed be obtained by distilling many vegetable substances, but it is produced during the operation. One or other of these alkalies is found in every plant which has hitherto been examined. The quantity indeed is usually very small.

77 Proportion of potass in plants.
1. Potass is found in almost all plants which grow at a distance from the sea. It may be extracted by burning the vegetable, washing the ashes in water, filtrating the water, and evaporating it to dryness. It is in this manner that all the potash of commerce is procured.

The following table exhibits the quantity of ashes and potass which may be extracted from 100 parts of various plants:

	Ashes.	*Potass.*
Sallow	2.8	0.285*(c)
Elm	2.36727	0.39*
Oak	1.35185	0.15343
Poplar	1.23476	0.07481
Hornbeam	1.1283	0.1254
Beech	0.58432	0.14572
Fir	0.34133	
Vine branches	3.379	0.55*
Common nettle	10.67186	2.5033
Common thistle	4.04265	0.53734
Fern	5.00781	0.6259
Cow thistle	10.5	1.96603
Great river rush	3.85395	0.72234
Feathered rush	4.33593	0.50811
Stalks of turkey wheat	8.86	1.75*
Wormwood	9.744	7.3*
Fumitory	21.9	7.9*
Trifolium pratense		0.078*
Vetches		2.75*
Beans with their stalks		2.0*

In general, three times as much ashes are obtained from shrubs, and five times as much from herbs, as from trees. Equal weights of the branches of trees produce more ashes than the trunk, and the leaves more than the branches. Herbs arrived at maturity produce more ashes than at any other time. Green vegetables produce more ashes than dry †.

† Ann. de Chim. xx. 174.

The salt which is obtained from plants does not consist wholly of potass, there are other salts mixed with it; these usually are sulphat of potass, muriat of potass, sulphat of lime, phosphat of lime, &c.; but these bear, in general, but a small proportion to the potass. The ashes consist of potass mixed with earths.

Some judgment may be formed of the quantity of potass which a plant contains from the quantity of ashes which it yields: but the above table is sufficient to shew us, that were we to trust to that we would often be misled.

2. Soda is found in almost all the plants which grow in the sea, and in many of those which grow on the shore. In general, the quantity of soda which plants contain bears a much greater proportion to their weight than the potass does which is found in inland vegetables. 100 parts of the *salsola soda*, for instance, yield 19.921 of ashes; and these contain 1.992 parts of soda, some of which, however, is combined with muriatic acid *. The plants from which the greater part of the soda, or *barilha*, as it is called, which is imported from Spain, is extracted, are the *salsola sativa*, and *vermiculata*.

* Vauquelin, Ann. de Chim. xviii. 77.

SECT. XVII. *Of EARTHS.*

THE only earths hitherto found in plants are the four following; *lime, silica, magnesia, alumina.*

79 Lime.
1. Lime is usually the most abundant of the earths of plants, and the most generally diffused over the vegetable kingdom. Indeed, it is a very uncommon thing to find a plant entirely destitute of lime: salsola soda is almost the only one in which we know for certain that this earth does not exist *.

* Id. ibid.

80 Silica.
2. Silica exists also in many plants, particularly grasses and equisetums. Mr Davy has ascertained, that it forms a part of the epidermis, or outermost bark of these plants; and that in some of them almost the whole epidermis is silica.

		Parts Silica.
100 parts of the epid. of	bonnet-cane yielded	90
	bamboo	71.4
(arundo phragm.)	common reed	48.1
	stalks of corn	6.5

The concretions which are sometimes found in the bamboo cane have been ascertained by Mr Macie to be composed of pure silica.

81 Magnesia.
3. Magnesia does not exist so generally in the vegetable kingdom as the two preceding earths. It has been found, however, in considerable quantities in several sea plants, especially fuci †. But the salsola soda contains a greater proportion of magnesia than any plant hitherto examined. Mr Vauquelin found that 100 parts of it contained 17.929 of that earth ‡.

† Id. ibid. 90. and ix. 94.
‡ Ibid. 78.

82 Alumina.
4. Alumina has only been found in very small quantities in plants.

83 Proportion of earth in plants.
The following table will shew the quantity of these four earths which exist in several vegetables.

100 parts of	oak contain of earths	1.03*
	Beech	0.453†
	Fir	0.003†
	Turkey wheat	7.11†
	Sunflower	3.72†
	Vine branches	2.85†
	Box	2.674†
	Willow	2.515†
	Elm	1.96†
	Aspin	1.146†
	Fern	3.221‡
	Wormwood	2.444§
	Fumitory	14.000§

Metals. Vegetation.

This table shews us, that the quantity of earth is greater in herbs than in trees.

Bergman found all the four earths in every kind of grain which he analysed *.

Vaquelin found, that 100 parts of oat grain left 3.1591 of residuum. This residuum is composed of

60 7 silica,
39 3 phosphat.

100.0 †.

When the whole of the avena sativa, however, stalk and seed together, are burnt, they leave a residuum composed of

55 silica,
15 phosphat of lime,
20 potass,
5 carbonat of lime.

95, and a little oxyd of iron ‡.

This shews us that the stalk contains several substances not to be found in the grain.

* Opusc. v. 94.
† Ann de Chim. xxix. 17.
‡ Ibid. 19.

Sect. XVIII. Of Metals.

Several metallic substances have also been found in vegetables, but their quantity is exceedingly small; so small, indeed, that without very delicate experiments their presence cannot even be detected.

84 Three metals found in plants.

The metals hitherto discovered are iron, which is by far the most common, manganese, and gold.

Scheele first detected manganese in vegetables *. Proust found it in the ashes of the pine, calendula, vine, green oak, and fig-tree †. M. Sage has shewn, that gold exists in many plants. Iron exists in most plants. The ashes of some species of salsola contain a considerable quantity of it.

* Opusc. i. 06.
† Phil. Mag. v. 9.

We have now taken a survey of all the substances which have hitherto been obtained from vegetables: by [illegible] of these, we come at last to those bodies which we are at present obliged to consider as simple, because they have not yet been decomposed, and of which accordingly we must suppose that vegetables are ultimately composed. These bodies amount to 16, namely,

85 Simple substances contained in plants.

1. Oxygen,	9. Gold,
2. Sulphur,	10. Lime,
3. Phosphorus,	11. Magnesia,
4. Carbon,	12. Silica,
5. Hydrogen,	13. Alumina,
6. Azot,	14. Potass,
7. Iron,	15. Soda,
8. Manganese,	16. Muriatic acid.

But of these substances there are twelve which compose but a very small proportion indeed of vegetables. Almost the whole of vegetable substances are composed of four ingredients, namely,

Carbon, Oxygen,
Hydrogen, Azot.

Of these the last, namely azot, forms but a small proportion even of those vegetable substances of which it is a constituent part, while into many it does not enter at all: So that, upon the whole, by far the greater part of vegetable substances is composed of carbon, hydrogen, and oxygen. We do not mention caloric and light, concerning the nature of which too little is known to enable us to determine with certainty into what substances they enter.

The substances at present known to chemists, which they have not been hitherto able to decompose, amount (omitting caloric and light) to 40. Sixteen of these exist in plants; the other 24 belong exclusively to the mineral kingdom: for it is a fact, that no substance (we mean simple substance) has been hitherto found in the animal kingdom which does not exist also in vegetables.

On the contrary, all the simple substances at present known may be found in minerals. This indeed ought not to surprise us, if we recollect, that the spoils of animals and vegetables, after they have undergone decomposition, are ultimately confounded with minerals, and consequently arranged under the mineral kingdom. Besides, as vegetables draw all their food from the mineral kingdom, it would be absurd to suppose that they contain substances which they could not have procured from minerals. It must follow, therefore, of necessity, that minerals contain all the simple substances which exist in this globe of our's; and that plants owe their diversity merely to different modifications of those principles which they imbibe from the soil. But it is impossible to have any precise notions about a subject so intricate, without considering with some attention the structure of vegetables, the food which they imbibe, and the changes which they produce on that food. These enquiries shall form the subject of the next chapter; in which we propose to take a view of those phenomena of vegetation which are connected with chemistry, or which may be elucidated by the application of the principles of that science.

Chap. II. Of Vegetation.

We have now seen the different substances which are contained in plants; but we have still to examine the manner in which these substances are produced, and to endeavour to trace the different processes which constitute vegetation. We must warn our readers not to expect complete information in this chapter. The wonders of the vegetable kingdom are still but very imperfectly explored; many of the organs of plants are too minute for our senses; and scarcely a single process can be completely traced.

86 Phenomena of vegetation very numerous.

The multiplicity of operations continually going on in vegetables at the same time, and the variety of different, and even opposite substances, formed out of the same ingredients, and almost in the same place, astonish and confound us. The order, too, and the skill with which every thing is conducted, are no less surprising. No two operations clash; there is no discord, no irregularity, no disturbance; every object is gained, and every thing is ready for its intended purpose. This is too wonderful to escape our observation, and of too much importance not to claim our attention. Many philosophers, accordingly, distinguished equally by their industry and sagacity, have dedicated a great part of their lives to the study of *vegetation*. But hitherto their success has not been equal to their exertions. No person has been able to detect this *agent*, always so busy, and performing such wonders, or to discover him at his work; nor have philosophers been much more fortunate

Vegeta-nate in their attempts to ascertain the instruments which he employs in his operations. A great variety, however, of curious and interesting facts, have been discovered. These we shall attempt in this chapter to collect and arrange, to point out their dependence on each other, and perhaps to deduce such consequences as obviously result from this mutual dependence.

87 Plant from seed.

1. Natural historians have proved, by a very complete induction of facts, that all plants arise from *seeds*. The pretended exceptions have disappeared, one after another, as our knowledge of vegetables increased: and now there remains scarcely a single objection entitled to the smallest regard. The late attempt of Girtanner * to revive the doctrine of equivocal generation, deserves no attention whatever; because his conclusions are absolutely incompatible with the *experiments* of Mr Senebier upon the very substance on which his theory is founded.

* *Ann. de Chim.* xxxiv 35.

88 Seeds composed of three parts.

A SEED consists of three parts; namely, the *cotyledons*, the *radicle*, and the *plumula*, which are usually inclosed in a cover.

If we take a garden bean, we may perceive each of these three parts with great ease; for this seed is of so large a size, that all its organs are exceedingly distinct.

When we strip off the external coats of the bean, which are two, and of different degrees of thickness in different parts, we find that it easily divides into two lobes, pretty nearly of the same size and figure. Each of these lobes is called a *cotyledon* (fig. 1. *a*). The cotyledons of the bean, then, are two in number.

Plate XLIII.

Near that part of the lobes which is contiguous to what is called the *eye* of the bean, there is a small round white body (*b*), which comes out between the two lobes. This body is called the *radicle*.

Attached to the radicle, there is another small round body (*c*), which lies between the cotyledons and wholly within them, so that it cannot be seen till they are separated from each other. This body is called the *plumula*.

The appearance and shape of these three parts differ very much in different seeds, but there is no seed which wants them. The figure and size of the seed depend chiefly upon the cotyledons. This is evidently the case with the bean, and it is so with all other seeds. The number of cotyledons is different in different seeds. Some seeds have only one cotyledon, as the seeds of wheat, oats, barley, and the whole tribe of grasses: some have three; others six, as the seeds of the garden grass; but most seeds, like the bean, have two cotyledons.

89 Germination of seeds

2. When a seed is placed in a situation favourable to vegetation, it very soon changes its appearance. The radicle is converted into a root, and sinks into the earth; the plumula, on the other hand, rises above the earth, and becomes the trunk or stem. When these changes take place, the seed is said to *germinate*: the process itself has been called *germination*. Seeds do not germinate equally and indifferently in all places and seasons. Germination, therefore, is a process which does not depend upon the seed alone, something external must also affect it.

90 Requires moisture,

3. It is a well known fact, that seeds will not germinate unless *moisture* have access to them; for seeds, if they are kept perfectly dry, never vegetate at all, and yet their power of vegetating is not destroyed. There are indeed some apparent objections to this: potatoes, for instance, and other bulbous bodies, germinate, tho' kept ever so dry. But the reason of this is, that these bodies (which are not seeds, though they resemble them in some particulars) have a sufficient quantity of water within themselves to give a beginning to germination. We may conclude, then, that no seed will germinate unless water has access to it. *Water*, then, is essential to germination. Too much water, however, is no less prejudicial to most seeds than none at all. The seeds of water plants, indeed, germinate and vegetate extremely well in water; but most other seeds, if they are kept in water beyond a certain time, are rotted and destroyed altogether.

91 Heat,

4. It is well known also, that seeds will not germinate, even though supplied with water, provided the temperature be below a certain degree. No seed, for instance, on which the experiment has been tried, can be made to vegetate at or below the freezing point: yet this degree of cold does not injure the vegetating power of seeds; for many seeds will vegetate as well as ever after having been frozen, or after having been kept in frozen water. We may conclude, then, that a certain degree of heat is necessary for the germination of seeds. And every species of plants seems to have a degree peculiar to itself, at which its seeds begin to germinate; for we find that almost every seed has a peculiar season at which it begins to germinate, and this season varies always according to the temperature of the air. Mr Adanson found that seeds, when sown at the same time in France and in Senegal, always appeared sooner above ground in the latter country, where the climate is hotter, than in France §.

§ *Sen. Mém. Physiol. Veget.* 124.

92 And oxygen gas.

5. Seeds, although supplied with moisture, and placed in a proper temperature, will not germinate, provided atmospherical air be completely excluded from them. Mr Ray found that grains of lettuce did not germinate in the vacuum of an air-pump, but they began to grow as soon as air was admitted to them ‡. Homberg made a number of experiments on the same subject, which were published in the Memoirs of the French Academy for the year 1693. He found, that the greater number of seeds which he tried refused to vegetate in the vacuum of an air-pump. Some, however, did germinate. But Boyle, Muschenbroek, and Boerhaave, who made experiments on the same subject in succession, proved beyond a doubt that no plant vegetates in the vacuum of an air-pump; and that in those cases in which Homberg's seeds germinated, the vacuum was far from perfect, a quantity of air still remaining in the receiver. It follows, therefore, that no seed will germinate unless atmospherical air, or some air having the same properties, have access to it. It is for this reason that seeds will not germinate at a certain depth below the surface of the earth.

‡ *Phil. Trans.* No 55.

Mr Scheele found that beans would not germinate except oxygen gas were present; Mr Achard afterwards proved, that oxygen gas is absolutely necessary for the germination of all seeds, and that no seed will germinate in azotic gas, or hydrogen gas, or carbonic acid gas, unless these gases contain a mixture of oxygen gas. These experiments have been confirmed by Mr

Vegetation.

Mr Gough, Mr Cruickfhank, and many other philofophers. It follows, therefore, that it is not the whole atmofpheric air, but merely the oxygen gas which it contains, that is neceffary for the germination of feeds.

93 [Injured by the prefence of light.]

6. Seeds do not germinate equally well when they are expofed to the light, and when they are kept in a dark place; light therefore has fome effect on germination.

Mr Ingenhoufz found, that feeds always germinate fafter in the dark than when expofed to the light *. His experiments were repeated by Mr Senebier with equal fuccefs †; and it was concluded, in confequence of their experiments, that light is injurious to germination. But the Abbé Bertholin, who diftinguifhed himfelf fo much by his labours to demonftrate the effect of electricity on vegetation, objected to the conclufions of thefe philofophers, and affirmed, that the difference in the germination of feeds in the fhade and in the light was owing, not to the light itfelf, but to the difference of the moifture in the two fituations; the moifture evaporating much fafter from the feeds in the light than from thofe in the fhade; and he affirmed, that when precautions were taken to keep the feeds equally moift, thofe in the fun germinated fooner than thofe in the fhade ‡. But when Mr Senebier repeated his former experiments, and employed every poffible precaution to enfure the equality of moifture in both fituations, he conftantly found the feeds in the fhade germinate fooner than thofe in the light §. We may conclude, therefore, that light is injurious to germination; and hence one reafon for covering feeds with the foil in which they are to grow.

7. Thus we have feen that feeds will not germinate unlefs *moifture*, *heat*, and *oxygen gas*, be prefent; and that they do not germinate well if they are expofed to [illegible]. Now, in what manner do thefe [illegible] the feed? What are the changes which [illegible]

94 [Phenomena of germination.]

[illegible], that all feeds have one or more cotyledons. These cotyledons contain a quantity of farinaceous matter, laid up on purpofe to fupply the embryo plant with food as foon as it begins to require it. This food, however, muft undergo fome previous preparation, before it can be applied by the plant to the formation or completion of its organs. Now all the phenomena of germination which [illegible], confift in the chemical [illegible] in that food, and the confequent [illegible] of the organs of the plant.

95 [The cotyledons prepare food,]

When a feed is placed in favourable circumftances, it gradually imbibes moifture, and very foon after emits a quantity of carbonic acid gas, even though no oxygen gas be prefent *. This feems to prove, as Mr Cruickfhank has fuppofed, that fome of the water imbibed by the feed is decompofed, that its oxygen combines with part of the carbon of the farina, and goes off in the form of carbonic acid gas, while the hydrogen remains behind, and combines with the ingredients contained in the cotyledon. The firft part of germination, then, confifts in diminifhing the quantity of carbon, and increafing the hydrogen of the farina. If no oxygen gas be prefent, the procefs ftops here, and no germination takes place.

But if oxygen gas be prefent, it is gradually abforbed and retained by the feed; and at the fame time, the farina of the cotyledons affumes a fweet tafte refembling fugar: it is therefore converted into fugar, or fome fubftance analogous to it †. Farina, then, is changed into fugar, by diminifhing its carbon, and augmenting the proportion of its hydrogen and oxygen. This is precifely the procefs of malting, or of converting grain into malt; during which it is well known that there is a confiderable heat evolved; fo much indeed, that in certain circumftances grain improperly kept has even taken fire. We may conclude from this, that during the germination of feeds in the earth there is alfo an evolution of a confiderable portion of heat. This indeed might have been expected, as it ufually ha[illegible] when oxygen gas is abforbed.

So far feems to be the work of chemiftry [illegible] at leaft we have no right to conclude that any other agent interferes; fince *hay*, when it happens to imbibe moifture, exhibits nearly the fame proceffes. Carbonic acid gas is evolved, oxygen gas is abforbed, heat is produced fo abundantly, that the hay often takes fire: at the fame time a quantity of fugar is formed. It is owing to a partial change of the fame kind that old hay generally taftes much fweeter than new hay. Now we have no reafon to fuppofe that any agents peculiar to the vegetable kingdom refide in hay; as all vegetation, and all power of vegetating, are evidently deftroyed.

96 [Which paffes into the radicle.]

But when the farina in the feeds of vegetables is converted into fugar, a number of veffels make their appearance in the cotyledon. The reader will have a pretty diftinct notion of their diftribution, by infpecting fig. 2. Thefe veffels may indeed be detected in many feeds before germination commences, but they become much more diftinct after it has made fome progrefs. Branches from them have been demonftrated by Grew, Malpighi, and Hedwig, paffing into the radicle, and diftributed through every part of it. Thefe evidently carry the nourifhment prepared in the cotyledons to the radicle; for if the cotyledons be cut off even after the proceffes above defcribed are completed, germination, as Bonnet and Senebier afcertained by experiment, immediately ftops. The food therefore is conveyed from the cotyledons into the radicle, the radicle increafes in fize, affumes the form of a *root*, finks down into the earth, and foon becomes capable of extracting the nourifhment neceffary for the future growth of the plant. Even at this period, after the radicle has become a perfect root, the plant, as Senebier afcertained by experiment, ceafes to vegetate if the *cotyledons* be cut off. They are ftill then abfolutely neceffary for the vegetation of the plant.

97 [And converts it into a root.]

98 [Cotyledons become feminal leaves.]

The cotyledons now affume the appearance of leaves, and appear above the ground, forming what are called the *feminal leaves* of the plant. After this the *plumula* gradually increafes in fize, rifes out of the earth, and expands itfelf into branches and leaves. The feminal leaves, foon after this, decay and drop off, and the plant carries on all the proceffes of vegetation without their affiftance.

Mr Eller attempted to fhew, that there is a veffel in feeds which paffes from the cotyledons to the plumula; but later anatomifts have not been able to perceive any fuch veffel. Even Mr Hedwig, one of the moft patient, acute, and fuccefsful philofophers that ever turned their attention to the ftructure of vegetables, could never

* Experiences fur les Vegetaux, ii.

† Mem. Phyfico-Chimique, iii. 41.

‡ Jour. de Phyf. 1789, Decemb.

§ Enc Meth. Phyfiol. Veg. i. 126.

* Gough, Manch. Mem. iv. 15. Cruickfhank, Rollo on Diabetes, 452.

† Ibid.

never diſcover any ſuch veſſel, although he traced the veſſels of the cotyledons even through the radicle. As it does not appear, then, that there is any communication between the cotyledons and the plumula, it muſt follow that the nouriſhment paſſes into the plumula from the radicle: and accordingly we ſee, that the plumula does not begin to vegetate till the radicle has made ſome progreſs. Since the plant ceaſes to vegetate, even after the radicle has been converted into a root, if the cotyledons be removed before the plumula is developed, it follows, that the radicle is inſufficient of itſelf to carry on the proceſſes of vegetation, and that the cotyledons ſtill continue to perform a part. Now we have ſeen already what that part is: they prepare *food* for the nouriſhment of the plant. The root, then, is of itſelf inſufficient for this purpoſe. When the cotyledons aſſume the form of ſeminal leaves, it is evident that the nouriſhment which was originally laid up in them for the ſupport of the embryo plant is exhauſted, yet they ſtill continue as neceſſary as ever. They muſt therefore receive the nouriſhment which is imbibed by the root; they muſt produce ſome changes on it, render it ſuitable for the purpoſes of vegetation, and then ſend it back again to be tranſmitted to the plumula.

99 Which prepare the food ſent from the root.

After the plumula has acquired a certain ſize, which muſt be at leaſt a *line*, if the cotyledons be cut off, the plant, as Mr Bonnet aſcertained by a number of experiments, afterwards repeated with equal ſucceſs by Mr Senebier, does not ceaſe to vegetate, but it continues always a mere pigmy: its ſize, when compared with that of a plant whoſe cotyledons are allowed to remain, being only as 2 to 7*.

* Enc Meth. Phyſiol Veget. 41.

100 Plumula forms the ſtem and leaves.

When the plumula has expanded completely into leaves, the cotyledons may be removed without injuring the plant, and they very ſoon decay of themſelves. It appears, then, that this new office of the cotyledons is afterwards performed by that part of the plant which is above ground.

Thus we have traced the phenomena of germination as far as they have been detected. The facts are obvious; but the *manner* in which they are produced is a profound ſecret. We can neither explain how the food enters into the veſſels, how it is conveyed to the different parts of the plant, how it is depoſited in every organ, nor how it is employed to increaſe the ſize of the old parts, or to form new parts. Theſe phenomena are analogous to nothing in mechanics or chemiſtry. He that attempts to explain them on the principles of theſe ſciences, merely ſubſtitutes new meanings of words inſtead of old ones, and gives us no aſſiſtance whatever in conceiving the proceſſes themſelves. As the ſubſtances employed in vegetation are all material, it is evident that they poſſeſs the properties of matter, and that they are arranged in the plant according to theſe laws. It follows, therefore, that all the changes which take place in the plant are produced according to the known laws of mechanics and chemiſtry. This cannot be diſputed: but it explains nothing; for what we want to know is the *agent* that brings every particle of matter to its proper place, and enables the laws of chemiſtry and mechanics to act only in order to accompliſh a certain end. Who is the agent that acts according to this end? To ſay that it is chemiſtry or mechanics is to pervert the uſe of words. For what are the laws of chemiſtry and mechanics? Are they not certain fixed and unalterable properties of matter? Now, to ſay that a property of matter has an end in view, or that it acts in order to accompliſh ſome deſign, is a downright abſurdity. There muſt therefore be ſome agent in all caſes of germination, which regulates and directs the mechanical and chemical proceſſes, and which therefore is neither a mechanical nor chemical property.

8. When the proceſs of germination is accompliſhed, the plant is complete in all its parts, and capable of vegetating in a proper ſoil, for a time and with a vigour proportional to its nature.

101 Plants compoſed of bark, wood, and pith.

Plants, as every body knows, are very various, and of courſe the ſtructure of each ſpecies muſt have many peculiarities. Trees have principally engaged the attention of anatomiſts, on account of their ſize and the diſtinctneſs which they expected to find in their parts. We ſhall therefore take a tree as an inſtance of the ſtructure of plants; and we ſhall do it the more readily, as the greater number of vegetables are provided with analogous organs, dedicated to ſimilar uſes.

A TREE is compoſed of a *root*, a *trunk*, and *branches*; the ſtructure of each of which is ſo ſimilar, that a general deſcription of their component parts will be ſufficient. Each of them conſiſts of three parts, the *bark*, the *wood*, and the *pith*.

102 Bark,

The BARK is the outermoſt part of the tree. It covers the whole plant from the extremity of the roots to the extremity of the branches. It is uſually of a green colour: if a branch of a tree be cut acroſs, the bark is eaſily diſtinguiſhed from the reſt of the branch by this colour. If we inſpect ſuch a horizontal ſection with attention, we ſhall perceive that the bark itſelf is compoſed of three diſtinct bodies, which, with a little care, may be ſeparated from each other. The outermoſt of theſe bodies is called the *epidermis*, the middlemoſt is called the *parenchyma*, and the innermoſt, or that next the wood, is called the *cortical layers*.

103 Compoſed of epidermis,

The *epidermis* is a thin tranſparent membrane, which covers all the outſide of the bark. It is pretty tough. When inſpected with a microſcope, it appears to be compoſed of a number of ſlender fibres croſſing each other, and forming a kind of network. It ſeems even to conſiſt of different thin retiform membranes, adhering cloſely together. This, at leaſt, is the caſe with the epidermis of the birch, which Mr Duhamel ſeparated into ſix layers. The epidermis, when rubbed off, is reproduced. In old trees it cracks and decays, and new epidermes are ſucceſſively formed. This is the reaſon that the trunks of many old trees have a rough ſurface.

104 Parenchyma,

The *parenchyma* lies immediately below the epidermis; it is of a deep green colour, very tender, and ſucculent. When viewed with a microſcope, it ſeems to be compoſed of fibres which croſs each other in every direction, like the fibres which compoſe a hat. Both in it and the epidermis there are numberleſs interſtices, which have been compared to ſo many ſmall bladders.

105 And cortical layers.

The *cortical layers* form the innermoſt part of the bark, or that which is next to the wood. They conſiſt of ſeveral thin membranes, lying the one above the other; and their number appears to increaſe with the age of the plant. Each of theſe layers is compoſed of longitudinal fibres, which ſeparate and approach each other alternately, ſo as to form a kind of network. The meſhes of this network correſpond in each of the lay-

Vegetables. ers; and they become smaller and smaller in every layer as it approaches the wood. These meshes are filled with a green coloured cellular substance, which has been compared by anatomists to a number of bladders adhering together, and communicating with each other.

106 Wood composed of

The WOOD lies immediately under the bark, and forms by far the greatest part of the trunk and large branches of trees. It consists of concentric layers, the number of which increases with the age of the part. Each of these layers, as Mr Du Hamel ascertained, may be separated into several thinner layers, and these are composed chiefly of longitudinal fibres. Hence the reason that wood may be much more easily split asunder than cut across.

The *wood*, when we inspect it with attention, is not, through its whole extent, the same; the part of it next the bark is much softer and whiter, and more juicy than the rest, and has for that reason obtained a particular name: it has been called the *alburnum* or *aubier*.

107 Alburnum and perfect wood.

The *perfect wood* is browner, and harder, and denser, than the alburnum, and the layers increase in density the nearer they are to the centre. Sir John Hill gave to the innermost layer of wood the name of *corona*, or rather he gave this name to a thin zone which, according to him, lies between the wood and the pith.

108 Pith.

The PITH occupies the centre of the wood. It is a very spongy body, containing a prodigious number of cells, which anatomists have compared to bladders. In young shoots it is very succulent; but it becomes dry as the plant advances, and at last in the large trunks of many trees disappears altogether.

The LEAVES are attached to the branches of plants by their footstalks. [illegible] footstalks a number of [illegible] which [illegible] communicate with each [illegible] of the leaf [illegible] a very curious [illegible] fibres may be obtained separately, by [illegible] in moisture. Every other part of [illegible] may easily be rubbed off, [illegible] constituting [illegible] of the [illegible] there are two layers of these fibres, [illegible] constituted the upper and under surface of the leaf.

The whole leaf is covered with the epidermis of the plant; and this epidermis, as Saussure has shewn, contains in it a great number of glands. The other parts of the [illegible] at least Saussure has [illegible] composed of two different layers. The [illegible] between the fibres of the leaf are filled up by a pulpy-like substance, to which the green colour of the leaf is owing.

Such is a short description of the most conspicuous parts of plants. A more minute account would have been foreign to the subject of the present article.

110 Plants increase in size.

Plants, after they have germinated, do not remain stationary, but are continually increasing in size. A tree, for instance, every season, adds considerably to its former bulk. The root sends forth new shoots, and the old ones become larger and thicker. The same increment takes place in the branches and the trunk. When we examine this increase more minutely, we find that a new layer of wood, or rather of alburnum, has been added to the tree in every part, and this addition has been made just under the bark. We find, too, that a layer of alburnum has assumed the appearance of perfect wood. Besides this addition of vegetable fibre, a great number of leaves have been produced; and the tree puts forth flowers, and forms seeds.

111 Therefore require food.

It is evident from all this, that a great deal of new matter is continually making its appearance in plants. Hence, since it would be absurd to suppose that they *create* new matter, it must follow that they receive it by some channel or other. Plants, then, require food as well as animals. Now, what is this food, and whence do they derive it? These questions can only be answered by an attentive survey of the substances which are contained in vegetables, and an examination of those substances which are necessary for their vegetation. If we could succeed completely, it would throw a great deal of light upon the nature of soils and of manures, and on some of the most important questions in agriculture. But we are far indeed at present from being able to examine the subject to the bottom.

112 Water necessary.

1. In the first place, it is certain that plants will not vegetate without water; for whenever they are deprived of it, they wither and die. Hence the well known use of rains and dews, and the artificial watering of ground. We may conclude, then, that water is at least an essential part of the food of plants.

But many plants grow in pure water; and therefore it may be questioned whether water is not the only food of plants. This opinion was adopted very long ago, and numerous experiments have been made in order to demonstrate it. Indeed, it was the general opinion of the 17th century; and some of the most successful improvers of the physiology of plants, in the 18th century, have embraced it. The most zealous advocates for it were, Van Helmont, Boyle, Bonnet, Duhamel, and Tillet.

113 Supp. the whole food of plants;

Van Helmont planted a willow which weighed five pounds, in an earthen vessel filled with soil previously dried in an oven, and moistened with rain water. This vessel he sunk into the earth, and he watered his willow, sometimes with rain, and sometimes with distilled water. After five years it weighed $169\frac{1}{4}$ lbs. and the earth in which it was planted, when again dried, was found to have lost only two ounces of its original weight. Here, it has been said, was an increase of 164 lb. and yet the only food of the willow was pure water; therefore it follows that pure water is sufficient to afford nourishment to plants. The insufficiency of this experiment to decide the question was first pointed out by Bergman in 1773 *. He shewed, from the experiments of Margraff, that the rain water employed by Van Helmont contained in it as much earth as could exist in the willow at the end of five years. For, according to the experiments of Margraff, 1 lb. of rain water contains 1 gr. of earth †. The growth of the willow, therefore, by no means proves that the earth which plants contain has been formed out of water. Besides, as Mr Kirwan has remarked ‡, the earthen vessel must have often absorbed moisture, from the surrounding earth, impregnated with whatever substance that earth contained; for unglazed earthen vessels, as Hales * and Tillet † have shewn, readily transmit moisture.

* *Opusc.* v. 92.

† *Opusc.* ii. 15. and 19.

‡ *Irish Trans.* v. 150.

* *Veget. Stat.* i. 5.

† *Mem. Par.* 1772. 298.

114 But without reason.

Hence it is evident that no conclusion whatever can be drawn from this experiment; for all the substances which the willow contained, except water, may have been derived from the rain water, the earth in the pot, and the moisture imbibed from the surrounding soil.

The

Vegetation.

The experiments of Duhamel and Tillet are equally inconclusive; so that it is impossible from them to decide the question, Whether water be the sole nourishment of plants or not? We owe the solution of this difficulty to the experiments of Mr Hassenfratz, who pointed out the fallacy of those just mentioned.

He analysed the bulbous roots of hyacinths, in order to discover the quantity of water, carbon, and hydrogen, which they contained; and by repeating the analysis on a number of bulbs, he discovered how much of these ingredients was contained in a given weight of the bulb. He analysed also kidney beans and cress seeds in the same manner. Then he made a number of each of these vegetate in pure water, taking the precaution to weigh them beforehand, in order to ascertain the precise quantity of carbon which they contained. The plants being then placed, some within doors, and others in the open air, grew and flowered, but produced no seed. He afterwards dried them, collecting with care all their leaves and every other part which had dropt off during the course of the vegetation. On submitting each plant to a chemical analysis, he found that the quantity of carbon, which it contained, was somewhat less than the quantity which existed in the bulb or the seed from which the plant had sprung *.

* Ann de Chim. xiii. 158.

Hence it follows irresistibly, that plants growing in pure water do not receive any increase of *carbon;* that the water merely serves as a vehicle for the carbonaceous matter already present, and diffuses it thro' the plant. Water, then, is not the sole food of plants; for all plants during vegetation receive an increase of carbonaceous matter, without which they cannot produce perfect seeds, nor even continue to vegetate beyond a certain time; and that time seems to be limited by the quantity of carbonaceous matter contained in the bulb or the seed from which they grow. For Duhamel found, that an oak which he had raised by water from an acorn, made less and less progress every year. We see, too, that those bulbous roots, such as hyacinths, tulips, &c. which are made to grow in water, unless they be planted in the earth every other year, refuse at last to flower, and even to vegetate; especially if they produce new bulbous roots annually, and the old ones decay.

115 A certain proper.

So far, indeed, is water from being the sole food of plants, that in general only a certain proportion of it is serviceable, too much being equally prejudicial to them as too little. Some plants, it is true, grow constantly in water, and will not vegetate in any other situation; but the rest are entirely destroyed when kept immersed in that fluid beyond a certain time. Most plants require a certain degree of moisture, in order to vegetate well. This is one reason why different soils are required for different plants. Rice, for instance, requires a very wet soil: were we to sow it in the ground on which wheat grows luxuriously, it would not succeed; and wheat, on the contrary, would rot in the rice ground.

We should, therefore, in choosing a soil proper for the plants which we mean to raise, consider the quantity of moisture which is best adapted for them, and choose our soil accordingly. Now, the dryness or moisture of a soil depends upon two things; the nature and proportions of the earths which compose it, and the quantity of rain which falls upon it. Every soil contains at least three earths, silica, lime, and alumina, and sometimes also magnesia. The silica is always in the state of sand. Now soils retain moisture longer or shorter according to the proportions of these earths. Those which contain the greatest quantity of sand retain it the shortest, and those which contain the greatest quantity of alumina retain it longest. The first is a dry, the second a wet soil. Lime and magnesia are intermediate between these two extremes: they render a sandy soil more retentive of moisture, and diminish the wetness of a clayey soil. It is evident, therefore, that, by mixing together proper proportions of these four earths, we may form a soil of any degree of dryness and moisture that we please.

But whatever be the nature of the soil, its moisture must depend in general upon the quantity of rain which falls. If no rain at all fell, a soil, however retentive of moisture it be, must remain dry; and if rain were very frequently falling, the soil must be open indeed, if it be not constantly wet. The proportion of the different earths in a soil, therefore, must depend upon the quantity of rain which falls. In a rainy country, the soil ought to be open; in a dry country, it ought to be retentive of moisture. In the first, there ought to be a greater proportion of sand; in the second, of clay.

11. Almost all plants grow in the earth, and every soil contains at least silica, lime, alumina, and often magnesia. We have seen already that one use of these earths is to administer the proper [illegible] to the vegetables which grow in the soil. [illegible] all plants contain earths as a part of their [illegible] probable that earths also serve as a [illegible] has not yet indeed been shewn, that [illegible] vegetate in pure water do not contain [illegible] quantity of earth; but as earths are absolutely necessary for the perfect vegetation of plants, as they are contained in all plants, and are even found in [illegible], we can scarcely doubt that they are actually imbibed, though only in [illegible]

117 And salts;

12. We [illegible] that all plants contain [illegible] and if we analyse the most fertile soils, and the richest manures, we ne[illegible] them destitute of these substances. Hence it is probable that different salts enter as ingredients into the food of plants. It is probable also, that every plant absorbs particular kinds of salts. Thus sea plants yield soda by analysis, while inland plants furnish potass. The potass contained in plants has indeed been supposed to be the produce of vegetation; but this has not been proved in a satisfactory manner. We find potass in the very juices of plants, even more abundantly than in the vegetable fibres themselves. But this subject is still buried in obscurity; and indeed it is extremely difficult

2

(D) Mr Tennant has ascertained, that magnesia, when uncombined with carbonic acid gas, is injurious to corn when employed as a manure; and that lime, which contains a mixture of magnesia, likewise injures corn.—See *Phil. Trans.* 1799, p. 2. This important fact demonstrates, that earths are not mere vehicles for conveying water to plants.

ficult to make decisive experiments, on account of the very small quantity of potass which most plants contain.

The phosphorus, too, and the iron, and other metals which are found in plants, are no doubt absorbed by them as a part of their food. We may suppose also, that the sulphuric and muriatic acids, and perhaps even the nitric acid, when found in plants, are imbibed by them along with the rest of their aliment.

Nothing is at present known concerning those saline substances which form an essential part of the food of plants; though it has been long remarked that certain salts are useful as manures.

118 And carbon. 13 Water, then, and earths, and perhaps also salts, form a part of the food of plants. But plants contain carbon, which cannot be derived from any of these substances; consequently some substance or other besides, which contains carbon, must constitute a part of the food of plants.

Mr Giobert mixed together the four earths, silica, alumina, lime, magnesia, in the proper proportions, to constitute a fertile soil; and after moistening them with water, planted several vegetables in them; but none of his plants grew well till he moistened the artificial soil with water from a [illegible] *. Now it is known, from the experiments of [illegible], that this water contains carbon; [illegible] evaporated, it constantly left behind it a [illegible] of charcoal †. We know likewise, from a great [illegible] of experiments, that all fertile soils contain a [illegible] quantity of carbonaceous matter; for all of them, when exposed to heat, are susceptible of partial combustion, during which a quantity of carbon [illegible] Thus Fourcroy and Hassenfratz found, that [illegible] fertile soil contained [illegible] of oil; which, [illegible] suppose to con[illegible] 16 [illegible] part of [illegible]. But these [illegible] roots of ve[illegible] con[illegible] the roots of [illegible] of car[illegible]

119 Which must be in a particular state; But [illegible] particular [illegible] as food for plants [illegible] mixed with earths, is not [illegible] immediately, as a manure; yet [illegible] great quantity of carbon. Farther, it appears from the experiments of Mr Hassenfratz, that substances employed as manures produce effects in times proportioned to their degree of putrefaction; those substances which are most putrid producing the most speedy effects, and of course soonest losing their efficacy. Having manured two pieces of the same kind of soil, the one with a mixture of dung and straw highly putrefied, the other with the same mixture newly made, and the straw almost fresh; he observed that, during the first year, the plants which grew on the land manured with the putrefied dung produced a much better crop than the other: but the second year (no new dung being added), the ground which had been manured with the unputrified dung produced the best crop; the same thing took place the third year; after which, both seemed to be equally exhausted *. Here it is evident that the putrified dung acted soonest, and was soonest exhausted. It follows from this, that carbon only acts as a manure when in a particular state of combination; and this state, whatever it may be, is evidently produced by putrefaction. Another experiment of the same chemist renders this truth still more evident. He allowed shavings of wood to remain for about ten months in a moist place till they began to putrefy, and then spread them over a piece of ground by way of manure. The first two years this piece of ground produced nothing more than others which had not been manured at all; the third year it was better, the fourth year still better, the fifth year it reached its maximum of fertility; after which it declined constantly till the ninth, when it was quite exhausted †. Here the effect of the manure evidently depended upon its progress in putrefaction.

* Encyc. Meth. Phys. Veget. p. 275.

† Ann. de Chim. xiv. 56.

* [illegible]

† Ibid. p. 58.

120 And it [illegible] water. Now what is the particular state into which carbon must be reduced before it be fit for the food of plants? This subject has never been examined with attention; the different combinations of carbon having been in a great measure overlooked. And yet it is evident, that it is only by an accurate examination of these combinations, and a thorough analysis of manures, in order to discover what particular combinations of carbon exist in them, and in what the most efficacious manures differ from the rest, that we can expect to throw complete light upon the nature and use of manures, one of the most important subjects to which the farmer can direct his attention. We know, from the experiments of Mr Hassenfratz, that all those manures which act with efficacy and celerity contain carbon in such a state of combination, that it is soluble in water; and that the efficacy of the manure is proportional to the quantity of carbon so soluble. He found that all efficacious manures gave a brown colour to water, and that the water so coloured, when evaporated, left a residuum, which consisted in a great measure of carbon *. He observed, too, that the soil which gives the deepest colour to water, or which contains the greatest quantity of carbon soluble in water, is, other things being the same, the most fertile.

* Ibid. p. 56.

This is not, however, to be understood without limitation; for it is well known that if we employ excessive quantities of manure, we injure vegetation instead of promoting it. This is the reason that plants will not, as Mr Duhamel found by experiment, vegetate in saturated solutions of dung †.

† Mem. Par. 1748.

121 This state not carbonic acid gas; One of the combinations of carbon which is soluble in water, and with which we are best acquainted, is carbonic acid gas. It has been supposed by many philosophers, particularly by Mr Senebier, that this gas, dissolved in water, supplies plants with a great part of their carbon. But Mr Hassenfratz, on making the experiment, found, that the plants which he raised in water, impregnated with carbonic acid gas, differed in no respect from those which grew in pure water, and did not contain a particle of carbon which had not existed in the seeds from which they sprung ‡. This experiment proves, that carbonic acid gas, dissolved in water, does not serve as food for plants. It appears, however, from the experiments of Ruckert, that when plants growing in soil are watered daily with water impregnated with carbonic acid gas, they vegetate faster than when this watering is omitted. He planted two beans in

‡ Ann. de Chim. xiii. 325.

122 Though that gas is useful.

Vegetation.

in pots of equal dimensions, filled with garden mould. One of these was watered almost daily with distilled water, the other with water, every ounce of which was impregnated with half a cubic inch of carbonic acid gas. Both were placed in the open air, but in a situation where they were secure from rain. The bean treated with the water impregnated with carbonic acid gas appeared above ground nine days before the other, and produced 25 beans; whereas the other produced only 15. The same experiment was tried on other plants with equal success †. This shews us that carbonic acid gas is somehow or other useful to plants when they vegetate in mould; but it gives us no information about its mode of acting. Some soils, we know, are capable of decomposing it; for some soils contain the green oxyd of iron: and Gadolin has proved, that such soils have the property of decomposing carbonic acid gas *. Indeed almost all soils contain iron, either in the state of the brown or the green oxyd; and Beaumé has shewn, that oils convert the brown oxyd of iron into the green †. Now dung contains a quantity of oily substance; and this is the case also with rich soils. One use of manures, therefore, may be, to reduce the brown oxyd of iron to the green, that it may be capable of decomposing carbonic acid gas; and the carbon, thus precipitated, doubtless enters into some new combination, in which state it serves as food for plants.

Mr Humbolt has lately proved, that soils have the property of absorbing oxygen. It can scarcely be doubted that this absorption has an influence on vegetation, especially as watering plants with weak solutions of oxy-muriatic acid accelerates vegetation *. But we know too little of the subject at present to be able to specify precisely what that influence is.

123 Food absorbed by the roots.

14. Since the only part of plants which is contiguous to the soil is the root, and since the plant perishes when the root is pulled out of the ground, it is evident that the food of plants must be imbibed by the roots.

When we examine the roots, we do not find them to contain any large opening. The passages by which the food enters are too small for the naked eye. This shews us, that the food can enter plants only in a fluid state; and that consequently every thing which can be rendered useful as food for plants must be previously in a state of solution.

It seems most probable, that the whole, or the greatest part of the food, enters at the extremities of the roots; for Duhamel observed, that the portion of the soil which is soonest exhausted, is precisely that part in which the greatest number of the extremities of roots lies ‡. This shews us the reason why the roots of plants are continually increasing in length. By this means they are enabled, in some measure, to go in quest of nourishment. The extremities of the roots seem to have a peculiar structure adapted for the imbibing of moisture. If we cut off the extremity of a root, it never increases any more in length: therefore its use as a root has been in a great measure destroyed. But it sends out fibres from its sides which act the part of roots, and imbibe food by their extremity. Nay, in some cases, when the extremity of a root is cut off, the whole decays, and a new one is formed in its place. This, as Dr Bell informs us, is the case with the hyacinth †.

Since the food of plants must be in a fluid state, and since no plant will live if it be deprived of moisture, we may conclude that all its food is previously dissolved in water. As for the carbon, we know, that in all active manures it is in such a state of combination, that it is soluble in water. We know, too, that all the salts which we can suppose to make a part of the food of plants, are more or less soluble in water. Lime also is soluble in water, whether it be pure or in the state of a salt; magnesia and alumina may be rendered so by means of carbonic acid gas; and Bergman, Macie, and Klaproth, have shewn, that even silica may be dissolved in water. We can see, therefore, in general, though we have no precise notions of the very combinations which are immediately imbibed by plants, that all the substances which form essential parts of that food *may* be dissolved in water.

124 Dissolved in water.

125 Therefore fluid.

15. Since the food of plants is imbibed by their roots in a fluid state, it must exist in plants in a fluid state; and unless it undergoes alterations in its composition just when imbibed, we may expect to find it in the plant unaltered. If there were any method of obtaining this fluid food from plants before it has been altered by them, we might analyse it, and obtain by that means a much more accurate knowledge of the food of plants than we can by any other method. This plan indeed must fail, provided the food undergoes alteration just when it is absorbed by the roots: but if we consider, that when one species of tree is grafted upon another, each bears its own peculiar fruit, and produces its own peculiar substances, we can scarcely avoid thinking that the great changes, at least which the food undergoes after absorption, are produced, not in the roots, but in other parts of the plant.

If this conclusion be just, the food of plants, after being imbibed by the roots, must be carried to those organs where it is to receive new modifications, and to be rendered fit for being assimilated to the different parts of the plant. There ought therefore to be certain juices continually ascending from the roots of plants; and these juices, if we could get them pure and unmixed with the other juices or fluids which the plant must contain, and which have been secreted and formed from these primary juices, would be, very nearly at least, the food as it was imbibed by the plant. Now during the vegetation of plants, there actually are juices continually ascending from their roots. This juice has been called the *sap*, the *succus communis*, the *lymph* of plants. We shall adopt the first of these names, because it has been most generally received.

The first step towards an accurate knowledge of the food, and of the changes which take place during vegetation, is an analysis of the sap. The sap is most abundant during the spring. At that season, if a cut be made through the bark and part of the wood of some trees, the sap flows out very profusely. The trees are then said to *bleed*. By this contrivance any quantity of sap we think proper may be collected. It is not probable, indeed, that by this method we obtain the ascending sap in all its purity: it is no doubt mixed with the peculiar juices of the plant; but the less progress vegetation has made, the purer we may expect to find it; both because the peculiar juices must be in much smaller quantity, and because its quantity may

† *Crell's Annals*, 1788. ii. 399.

* *Ibid.* 1791. i. 53.

† *Kirw.*, *Irish Tr.* v. 150.

* *Ingenhousz.*

‡ *Physique des Arbres*, ii. 239.

† *Manch. Mem.* ii. 412.

 may be supposed to be greater. We should therefore examine the sap as early in the season as possible, and at all events before the leaves have expanded.

For the most complete set of experiments hitherto made upon the sap, we are indebted to Mr Vauquelin. An account of his experiments has been published in the 31st volume of the *Annales de Chimie*. He has neglected to inform us of the state of the tree when the sap which he analysed was taken from it; so that we are left in a state of uncertainty with respect to the purity of the sap: but from the comparison which he has put it in our power to draw between the state of the sap at different successive periods, we may in some measure obviate this uncertainty.

He found that 1039 parts of the sap of the ulmus campestris, or common elm, were composed of

1027.567 water and volatile matter,
9.553 acetite of potass,
1.062 vegetable matter,
0.818 carbonat of lime,

Besides some slight traces of sulphuric and muriatic acids.

On analysing the same sap somewhat later in the season, Mr Vauquelin found the quantity of vegetable matter a little increased, and that of the carbonat of lime and acetite of potass diminished. Still later in the season the vegetable matter was farther increased, and the other two ingredients farther diminished. The acetite of potass, in 1000 parts of this third sap, amounted to 8.615 parts.

If these experiments warrant any consequence to be drawn from them, they would induce us to suppose that the carbonat of lime and acetite of potass were contained in the [illegible] ascending sap, [illegible] part at least of the vegetable matter [illegible] from the peculiar juices altering [illegible] organs of the plant; for the two salts [illegible] and the vegetable matter increased [illegible] of the sap [illegible]. Now [illegible] ought to have taken place on the [illegible] become more and more mixed [illegible] of the sap [illegible] supposing [illegible] this conclusion have any validity, it follows [illegible] that carbonat of lime and acetite of potass are absorbed by plants as a part of their food. Now these salts [illegible] be dissolved in water [illegible] may be dissolved in water [illegible]. This shews us how water [illegible] acid may be useful to plants vegetating in a proper soil, while it is useless to those that vegetate in pure water. In the pure water there is no carbonat of lime to be dissolved; and therefore carbonic acid gas cannot enter into a combination which renders it proper for becoming the food of plants. Part of the vegetable matter was precipitated from the sap by alcohol. This part seems to have been gummy. Now gums we know are produced by vegetation.

The sap of the fagus sylvatica, or beech, contained the following ingredients.

Water,
Acetite of lime with excess of acid,
Acetite of potass,
Gallic acid,
Tan,
A mucous and extractive matter,
Acetite of alumina.

Although Mr Vauquelin made two different analyses of this sap at different seasons, it is impossible to draw any satisfactory conclusions from them, as he has not given us the proportions of the ingredients. It seems clear that the ga[illegible] tan were combined together; for the sap tasted like the infusion of oak bark. The quantity of each of these ingredients increased as vegetation advanced; for the colour of the second sap collected later was much deeper than that of the first. This shews us that these ingredients were produced by vegetation, and that they did not form a part of the ascending sap. Probably they were derived from the bark of the tree. The presence of alumina, and the absence of carbonic acid gas, would seem to indicate that all plants do not imbibe the very same food.

The sap of the carpinus sylvestris contains water, acetite of potass, acetite of lime, sugar, mucilage, vegetable extract. It cannot be doubted that the sugar and the mucilage are the produce of vegetation.

The sap of the betula alba, or common birch, contains water, sugar, vegetable extract, acetite of lime, acetite of alumina, and acetite of potass.

These experiments are curious, and certainly add to the precision of our notions concerning the food of plants; but they are not decisive enough to entitle us to draw conclusions. They would seem to shew, either that acetite of potass and lime are a part of the food of plants, or at least some substances which have the property of assuming these combinations.

16. These experiments lead to the conclusion that acetous acid forms a component part of the sap. Now it is not easy to suppose that this substance is actually absorbed by the roots in the state of acetous acid. The thing might be determined by examining the mould in which plants grow. This examination indeed has been performed; but no chemist has ever found acetous acid, at least in any sensible quantity. Is it not probable, then, that the food, after it is imbibed, is somewhat modified and altered by the roots? In what manner this is done we cannot say, as we know very little about the vascular structure of the roots. We may conclude, however, that this modification is nearly the same in most plants: for one plant may be engrafted on another, and each continue to produce its own peculiar products; which could not be, unless the proper substances were conveyed to the digestive organs of all. There are several circumstances, however, which render the modifying power of the roots somewhat probable. The strongest of these is the nature of the ingredients found in the sap. It is even possible that the roots may, by some means or other, throw out again some part of the food which they have imbibed as excrementitious. This has been suspected by several physiologists; and there are several circumstances which render it probable. It is well known that some plants will not vegetate well after others; and that some again vegetate unusually well when planted in ground where certain plants had been growing. These facts, without doubt, may be accounted for on other principles. If there be any excrementitious matter emitted by the roots, it is much more probable that this happens in the last stage of vegetation. That is to say, when the food, after digestion, is applied to the purposes which the root requires. But the fact ought to be supported by experiments, otherwise it cannot be admitted.

Vegetation.

112 Whether food is altered by the roots.

17. The

Vegetation.

17. The sap, as Dr Hales has shewn us, ascends with a very considerable force. It issued during the bleeding season with such impetuosity from the cut end of a vine branch, that it supported a column of mercury 32½ inches high *.

* Veg. Stat. i. 105.

129 Sap ascends

Now what is the particular channel through which the sap ascends, and what is the cause of the force with which it moves? These are questions which have excited a great deal of the attention of those philosophers who have made the physiology of vegetables their particular study; but the examination of them is attended with so many difficulties that they are very far from being decided.

It is certain that the sap flows from the roots towards the summit of the tree. For if in the bleeding season a number of openings be made in the tree, the sap begins first to flow from the lowest opening, then from the lowest but one, and so on successively, till at last it makes its appearance at the highest of all. And when Duhamel and Bonnet made plants vegetate in coloured liquors, the colouring matter, which was deposited in the wood, appeared first in the lowest part of the tree, and gradually ascended higher and higher, till at last it reached the top of the tree, and tinged the very leaves.

It seems certain, too, that the sap ascends through the wood, and not through the bark of the tree: for a plant continues to grow even when stript of a great part of its bark; which could not happen if the sap ascended through the bark. When an incision, deep enough to penetrate the bark, and even part of the wood, is carried quite round a branch, provided the wound be covered up from the external air, the branch continues to vegetate as if nothing had happened; which could not be the case if the sap ascended between the bark and the wood. It is well known, too, that in the bleeding season little or no sap can be got from a tree unless our incision penetrate deeper than the bark.

131 Not by the parenchyma;

If the sap ascended thro' the parenchyma of plants, as some physiologists have supposed, since there is a communication between every part of that organ, it is evident that the tree ought to bleed whenever any part of the parenchyma is wounded. But this is not the case. Consequently the sap does not ascend through the parenchyma. Besides, if the supposition were true, the sap, from the very structure of the parenchyma, must ascend in the same manner as water through a sponge; and in that case could not possibly possess the force with which we know that it ascends. But if the sap is not found in the parenchyma, as is now well known to be the case, it must, of necessity, be confined in particular vessels; for if it were not, it would undoubtedly make its appearance there. Now what are the vessels through which the sap ascends?

But in vessels.

Grew and Malpighi, the first philosophers who examined the structure of plants, took it for granted that ascended [illegible]

[illegible] a tube; and succeeding observers have been equally unsuccessful. The conjecture therefore of Malpighi and Grew, about the nature and use of these fibres, remains totally unsupported by any proof. Duhamel has even gone far to overturn it altogether. For he found that these woody fibres are divisible into smaller fibres, and these again into still smaller; and even, by the assistance of the best microscopes, he could find no end of this subdivision *. Now granting these fibres to be vessels, it is scarcely possible, after this, to suppose that the sap really moves through tubes, whose diameters are almost infinitely small. There are, however, vessels in plants which may easily be distinguished by the help of a small microscope, and even, in many cases, by the naked eye. These were seen, and distinctly described, by Grew and Malpighi. They consist of a fibre twisted round like a corkscrew. If we take a small cylinder of wood, and wrap round it a slender brass wire, so closely that all the rings of the wire touch each other, and if, after this, we pull out the wooden cylinder altogether, the brass wire thus twisted will give us a very good representation of these vessels. If we take hold of the two ends of the brass wire thus twisted, and pull them, we can easily draw out the wire to a considerable length. In the same manner, when we lay hold of the two extremities of these vessels, we can draw them out to a great length. Malpighi and Grew finding them always empty, concluded that they were intended for the circulation of the air through the plant, and therefore gave them the name of *tracheæ*, which word is used to denote the *windpipe* of animals. These *tracheæ* are not found in the bark; but Hedwig has shewn that they are much more numerous in the wood than was supposed; and that they are of very different diameters; and Reichel has demonstrated that they go to the [illegible] branches, and spread through every leaf. He has [illegible], too, that they contain sap; and Hedwig has proved that the notion which generally prevailed of their containing nothing but [illegible] the larger tracheæ [illegible] their sap as soon [illegible] they are inspected [illegible] appear empty †. Is it not probable, [illegible] not certain, from the discoveries [illegible] physiologists, that the tracheæ [illegible] vessels of plants? [illegible] experiments both of Reichel and Hedwig, that [illegible] almost all the [illegible] of plants [illegible] only to their structure [illegible].

* Physique des Arbres, i. 57.

† [illegible]

133 Why it ascends.

But by what [illegible] to ascend in these vessels? [illegible] to ascend, but to move with very [illegible] force, as Hales has shewn, sufficient to overcome the pressure of 43 feet perpendicular of water ‡.

‡ Veget. Stat. i. 107.

134 Hypothesis of Grew, Malpighi, and De la Hire.

Grew ascribed this phenomenon to the levity of the sap; which, according to him, entered the plant in the state of a very light vapour. But this opinion will not bear the slightest examination. Malpighi supposed that the sap was made to ascend by the contraction and dilatation of the air contained in the air vessels. But [illegible] tracheæ are air vessels, [illegible] could only ascend [illegible] place; which is [illegible] were to wave every [illegible] objection of that kind, the hypothesis would not account for the circulation of the sap, unless the sap vessels be provided with valves. Now the experiments of Hales and Duhamel shew that no valves can possibly exist in them. For branches imbibe moisture nearly equally

Vegetation.

equally by either end; and consequently the sap moves with equal facility both upwards and downwards, which it could not do were there valves in the vessels. Besides, it is known, from many experiments, that we may convert the roots of a tree into the branches, and the branches into the roots, by covering the branches with earth, and exposing the roots to the air. Now this would be impossible if the sap vessels were provided with valves. The same remarks overturn the hypothesis of Mr de la Hire, which is merely that of Malpighi, expressed with greater precision, and with a greater parade of mechanical knowledge. Like Borelli, he placed the ascending power of the sap in the parenchyma. But his very experiments, had he attended to them with care, would have been sufficient to shew the imperfection of his theory.

The greater number of philosophers (for it is needless to mention those who, like Perrault, had recourse to fermentation, nor those who introduced the weight of the atmosphere) have ascribed the motion of the sap to *capillary attraction.*

Ascribed to capillary attraction

There exists a certain attraction between many solid bodies and liquids; in consequence of which, if these solid bodies be formed into small tubes, the liquid enters them, and rises in them to a certain height. But this is perceptible only when the diameter of the tube is very small; [illegible] the attraction has been denominated *capillary*. We know that there is such an attraction between vegetable fibres and watery liquids. For such [illegible] through [illegible] vegetable [illegible] probable, therefore, that the food of plants enters the roots in consequence of the capillary attraction which [illegible] between the sap vessels and the liquid imbibed. [illegible] attraction then, [illegible] well [illegible] of moisture [illegible] But will it account [illegible] the ascent of the sap, [illegible] have [illegible] But we [illegible] decide [illegible] attrac[illegible] of the [illegible] not extend, or at [illegible] at greater distance [illegible] It has been demonstrated [illegible] by the capillary attraction [illegible] but of a slender film of it; and Clairaut has shewn that this film is situated at the lowermost extremity of the tube (G). This film attracts the liquid with a certain force; and if this force be greater than the cohesion between the particles of the liquid, part enters the tube, and continues to enter, till the quantity above the attracting film of the tube just equals, by its weight, the excess of the capillary attraction between the tube and the liquid, above the cohesion of the liquid. The quantity of water therefore in the tube is pretty nearly the measure of this excess; for the attracting film is probably very minute.

It has been demonstrated, that the heights to which liquids rise in capillary tubes, are inversely as the diameter of the tube. Consequently the smaller the diameter of the tube, the greater is the height to which the liquid will rise. But the particles of water are not infinitely small; therefore whenever the diameter of the tube is diminished beyond a certain size, water cannot ascend in it, because its particles are now larger than the bore of the tube. Consequently the rise of water in capillary tubes must have a limit: if they exceed a certain length, how small soever their bore may be, water will either not rise to the top of them, or it will not enter them at all. We have no method of ascertaining the precise height to which water would rise in a capillary tube, whose bore is just large enough to admit a single particle of water. Therefore we do not know the limit of the height to which water may be raised by capillary attraction. But whenever the bore is diminished beyond a certain size, the quantity of water which rises in it is too small to be sensible. We can easily ascertain the height which water cannot exceed in capillary tubes before this happens: and if any person calculate, he will find that this height is not nearly equal to the length of the sap vessels of many plants. But besides all this, we see in many plants very long sap vessels, of a diameter too large for a liquid to rise in them a single foot by capillary attraction, and yet the sap rises in them to very great heights.

If any person says that the sap vessels of plants gradually diminish in diameter as they ascend; and that, in consequence of this contrivance, they act precisely as an indefinite number of capillary tubes, one standing upon another, the inferior serving as a reservoir for the superior: we answer, that the sap may ascend by that means to a considerable height; but certainly not in any greater quantity than if the whole sap vessel had been precisely of the bore of its upper extremity. For the quantity of sap raised must depend upon the bore of the upper extremity, because it must all pass through that extremity. The quantity of sap, too, on that supposition, must diminish the farther we go from the root, because the bore of the sap vessels is constantly diminishing; the ascending force must also diminish, because it is, in all cases, proportional to the quantity of water raised. Now neither of these, as Dr Hales has demonstrated, is true.

157 Is it refuted.

But farther, if the sap moved only in the vessels of plants by capillary attraction, it would be so far from flowing out at the extremity of a branch, with a force sufficient to overcome the pressure of a column of water 43 feet high, that it could not flow out at all. It would be impossible in that case for any such thing as the bleeding of trees ever to happen.

If we take a capillary tube, of such a bore that a liquid will rise in it six inches, and after the liquid has risen to its greatest height, break it short three inches from the bottom, none of the liquid in the under half flows over. The tube, thus shortened, continues indeed full, but not a single particle of liquid ever escapes from it. And how is it possible for it to escape? The film,

(G) The action of all the other films, of which the tube is composed, on the water, as far as it is measured by its effect, is nothing at all. For every particle of water in the tube (except those attracted by the undermost film) is attracted upwards and downwards by the same number of films: it is therefore precisely in the same state as if it were not attracted at all.

Vegetation. film, at the *upper* extremity of the tube, must certainly have as strong an attraction for the liquid as the film at the *lower* extremity. As part of the liquid is within its attracting distance, and as there is no part of the tube above to counterbalance this attraction, it must of necessity attract the liquid nearest it, and with a force sufficient to counterbalance the attraction of the undermost film, how great soever we may suppose it. Of course no liquid can be forced up, and consequently none can flow out of the tube. Since then the sap *flows out* at the upper extremity of the sap vessels of plants, we are absolutely certain that it does not ascend in them merely by its capillary attraction, but that there is some other cause.

It is impossible therefore to account for the motion of the sap in plants by any mechanical or chemical principles whatever; and he, who ascribes it to these principles has not formed to himself any clear or accurate conception of the subject. We know indeed that heat is an agent; for Dr Walker found that the ascent of the sap is much promoted by heat, and that after it had begun to flow from several incisions, cold made it give over flowing from the higher orifices while it continued to flow at the lower*. But this cannot be owing to the dilating power of heat: for unless the sap vessels of plants were furnished with valves (and they have no valves), dilatation would rather retard than promote the ascent of the sap. Consequently the effect of heat can give us no assistance in explaining the ascent of the sap upon mechanical and chemical principles.

133 The vessels must contract. We must therefore ascribe it to some other cause: the vessels themselves must certainly act. Many philosophers have seen the necessity of this, and have accordingly ascribed the ascent of the sap to *irritability*. But the first person who gave a precise view of the manner in which the vessels probably act was Saussure. He supposes that the sap enters the open mouths of the vessels, at the extremity of the roots; that these mouths then contract, and by that contraction propel the sap upwards; that this contraction gradually follows the sap, pushing it up from the extremity of the root to the summit of the plant. In the mean time the mouths are receiving new sap, which in the same manner is pushed upwards †. Whether we suppose the contraction to take place precisely in this manner or not, we can scarcely deny that it must take place; but by what means it is impossible to say. The agents cannot precisely resemble the muscles of animals; because the whole tube, however cut or maimed, still retains its contracting power, and because the contraction is performed with equal readiness in every direction. It is evident, however, that they must be the same in kind. Perhaps the particular structure of the vessels may fit them for their office. Does ring after ring contract its diameter? The contracting agents, whatever they are, seem to be excited to act by some stimulus communicated to them by the sap. This capacity of being excited to action is known in physiology by the name of *irritability*; and there are not wanting proofs that plants are possessed of it. It is well known that different parts of plants move when certain substances act upon them. Thus the flowers of many plants open at sunrise, and close again at night. Linnæus has given us a list of these plants. Des Fontaines has shewn that the stamina and antheræ of many plants exhibit distinct motions ‡. Dr Smith has observed, that the stamina of the barberries are thrown into motions when touched §. Roth has ascertained that the leaves of the drosera longifolia and rotundifolia have the same property. Mr Coulon, too, who has adopted the opinion that the motion of the sap in plants is produced by the contraction of vessels, has even made a number of experiments in order to shew this contraction. But the fact is, that every one has it in his power to make a decisive experiment. Simply cutting a plant, the *euphorbia peplis* for instance, in two places, so as to separate a portion of the stem from the rest, is a complete demonstration that the vessels actually do contract. For whoever makes the experiment, will find that the milky juice of that plant flows out at both ends so completely, that if afterwards we cut the portion of the stem in the middle, no juice whatever appears. Now it is impossible that these phenomena could take place without a contraction of the vessels; for the vessels in that part of the stem which has been detached cannot have been *more* than full; and their diameter is so small, that if it were to continue unaltered, the capillary attraction would be more than sufficient to retain their contents, and consequently not a drop could flow out. Since, therefore, the whole liquid escapes, it must be driven out forcibly, and consequently the vessels must contract.

* Phil. Trans. l.

† Encyc. Meth. Phys. Veget. p 297.

‡ Mem. Par. 1787.

§ Phil. Trans. lxxviii.

It seems pretty plain, too, that the vessels are excited to contract by various stimuli; the experiments of Coulon and Saussure render this probable, and an observation of Dr Smith Barton makes it pretty certain. He found that plants growing in water vegetated with much greater vigour, provided a little camphor was thrown into the water*. 139 In consequence of stimuli.

18. Besides the sap which ascends upwards towards the leaves, they contain also another fluid, known by the name of *succus proprius*, or peculiar juice. This juice differs very considerably in different plants. It seems to be the sap altered by some process or other, and fitted for the various purposes of vegetation. That it flows from the leaves of the plant towards the roots, appears from this circumstance, that whenever we make an incision into a plant, into whatever position we put it, much more of the succus proprius flows from that side of the wound which is next the leaves and branches, than from the other side; and this happens even though the leaves and branches be held undermost †. When a ligature is tied round a plant, a swelling appears above, but not below the ligature.

† Bell. Manch. Mem. ii. 402.

The vessels containing the peculiar juice are found in all the parts of the plant. Hedwig, who has examined the vessels of plants with very great care, seems to consider them as of the same structure with the tracheæ. The peculiar juice is easily known by its colour and its consistence. In some plants it is green, in some red, in many milky. It cannot be doubted that its motion in the vessels is performed in the same way as that of the sap.

140 In the leaves. 19. It appears, then, that the sap ascends to the leaves, that there it undergoes certain alterations, and is converted into the peculiar juices; which, like the blood in animals, are afterwards employed in forming the various substances found in plants. Now the changes which the sap undergoes in the leaves, provided we can trace them, must throw a great deal of light upon the nature of vegetation.

No.

Vegetation.

141 Part of the sap perspires thro' the leaves.

No sooner has the sap arrived at the leaves, than a great part of it is thrown off by evaporation. The quantity thus perspired bears a very great proportion to the moisture imbibed. Mr Woodward found that a sprig of mint in 77 days imbibed 2558 grains of water, and yet its weight was only increased 15 grains *; therefore it must have given out 2543 grains. Another branch, which weighed 127 grains, increased in weight 128, and it had imbibed 14190 grains. Another sprig, weighing 76 grains, growing in water mixed with earth, increased in weight 168 grains, and had imbibed 10731 grains of water. These experiments demonstrate the great quantity of matter which is constantly leaving the plant. Dr Hales found that a cabbage transmitted daily a quantity of moisture equal to about half its weight; and that a sun flower, three feet high, transmitted in a day 1 lb. 14 oz. avoirdupois †. He shewed, that the quantity of transpiration in the same plant was proportional to the surface of the leaves, and that when the leaves were taken off, the transpiration nearly ceased ‡. By these observations, he demonstrated that the leaves are the organs of transpiration. He found, too, that the transpiration was nearly confined to the day, very little taking place during the night §; that it was much promoted by heat, and stopped by rain and frost ‖. And Millar ¶, Guettard *, and Senebier, have shewn that the transpiration is also very much promoted by sunshine.

¶ Ibid. 22.

* Mem. Par. 1748.

The quantity of moisture imbibed by plants depends very much upon what they transpire: the reason is evident; when the vessels are once filled with sap, if none be carried off, no more can enter; and, of course, the quantity which enters must depend upon the quantity emitted.

In order to discover the nature of the transpired matter, Hales placed plants in large glass vessels, and by that means collected a quantity of it †. He found that it resembled pure water in every particular, excepting only that it sometimes had the odour of the plant. He remarked, too, as Guettard and Du Hamel did after him, that when kept for some time it putrefied, or at least acquired a stinking smell. Senebier subjected a quantity of this liquid to a chemical analysis.

† Ibid. 49.

143 Its nature,

He collected 12030 grains of it from a vine during the months of May and June. After filtration he gradually evaporated the whole to dryness. There remained behind two grains of residuum. These two grains consisted of nearly ¼ grain of carbonat of lime, $\frac{1}{11}$ grain of sulphat of lime, ½ grain of matter soluble in water, and having the appearance of gum, and ½ grain of matter which was soluble in alcohol, and apparently resinous. He analyzed 60768 grains of the same liquid, collected from the vine during the months of July and August. On evaporation he obtained 2¼ grains of residuum, composed of ½ grain of carbonat of lime, ½ grain of sulphat of lime, ¼ grain of mucilage, and ½ grain of resin. The liquid transpired by the *aster novae Angliae* afforded precisely the same ingredients ‡.

‡ Enc. Method. Phys. Veget. 287.

144 And quantity.

Senebier attempted to ascertain the proportion which the liquid transpired bore to the quantity of moisture imbibed by the plant. But it is easy to see that such experiments are liable to too great uncertainties to be depended on. His method was as follows: He plunged the thick end of the branch on which he made the experiment into a bottle of water, while the other end, containing all its leaves, was thrust into a very large glass globe. The apparatus was then exposed to the sunshine. The quantity imbibed was known exactly by the water which disappeared from the bottle, and the quantity transpired was judged of by the liquid which condensed and trickled down the sides of the glass globe. The following table exhibits the result of his experiments:

Plants.	*Imbibed.*	*Perspired.*	*Time.*
Peach	100 gr.	35 gr.	
Ditto	210	90	
Ditto	220	120	
Mint	200	90	2 days
Ditto	575	120	10
Rasp	725	560	2
Ditto	1232	765	2
Peach	710	295	1
Apricot	210	180	1

In some of his experiments no liquid at all was condensed. Hence it is evident that the quantity of matter transpired cannot be deduced from these experiments. The mouth of the glass globe does not seem to have been accurately closed; the air within it communicated with the external air: consequently the quantity condensed must have depended entirely upon the state of the external air, the heat, &c.

The first great change, then, which takes place upon the sap after it arrives at the leaves, is the evaporation of a great part of it; consequently what remains must be very different in its proportions from the sap. The leaves seem to have particular organs adapted for throwing off part of the sap by transpiration. For the experiments of Guettard *, Duhamel †, and Bonnet ‡, shew that it is performed chiefly by the upper surfaces of leaves, and may be nearly stopped altogether by varnishing the upper surface.

* Mem. Par. 1748.

† Physique des Arbres, i. 138.

‡ Traité de l'usage des feuilles, 1. Mem.

145 Why the leaves fall off.

The leaves of plants become gradually less and less fit for this transpiration; for Senebier found, that when all other things are equal, the transpiration is much greater in May than in September *. Hence the reason that the leaves are renewed annually. Their organs become gradually unfit for performing their functions, and therefore it is necessary to renew them. Those trees which retain their leaves during the winter, were found by Hales and succeeding physiologists to transpire less than others. It is now well known that these trees also renew their leaves.

* En. Meth. 285.

20. Leaves have also the property of absorbing carbonic acid gas from the atmosphere.

146 Leaves absorb carbonic acid gas.

We are indebted for this very singular discovery to the experiments of Dr Priestley, though he himself did not discover the truth, and though he even refused to acknowledge it when it was pointed out by others. It has been long known, that when a candle has been allowed to burn out in any quantity of air, no candle can afterwards be made to burn in it. In the year 1771 Dr Priestley made a sprig of mint vegetate for ten days in contact with a quantity of such air; after which he found that a candle would burn in it perfectly well ¶. This experiment he repeated frequently, and found that it was always attended with the same result. According to the opinion at that time universally received, that the

Vegeta-tion.

the burning of candles rendered air impure by communicating phl[illegible]ston to [illegible] he concluded from it, that plants, whi[illegible] state, absorb phlogiston.

Carbonic [illegible] was at that time supposed to contain phlog[illegible]ton. It was natural, therefore, to suppose that it would afford nourishment to plants, since they had the property of absorbing phlogiston from the atmosphere Dr P[illegible]rcival had published a set of experiments; by which he endeavoured to shew that this was actually the case.

These experiments induced Dr Priestley, in 1776, to consider the subject with more attention. But as, in all the experiments which he made, the plants confined in carbonic acid gas very soon died, he concluded, that carbonic acid gas was not a food, but a poison to plants *. Mr Henry of Manchester was led, in 1784, probably by the contrariety of these results, to examine the subject. His experiments, which were published in the Manchester Transactions †, perfectly coincided with those of Dr Percival. For he found, that carbonic acid gas, so far from killing plants, constantly promoted their growth and vigour. Meanwhile Mr Senebier was occupied at Geneva with the same subject; and he published the result of his researches in his *Memoires Physico-chymique* about the year 1780. His experiments shewed, in the clearest manner, that carbonic acid gas is used by plants as food. The same thing was supported by Ingenhousz in his second volume. The experiments of Saussure the Son, published in 1797, have at last put the subject beyond the reach of dispute. From a careful comparison of the experiments of these philosophers, it will not be difficult for us to discover the various phenomena, and to reconcile all the seeming contradictions which occur in them. The facts are as follows:

* On Air i. 100.

† ii 341.

Mr Saussure has shewn, that plants will not vegetate when totally deprived of carbonic acid gas. They vegetate indeed well enough in air which has been previously deprived of carbonic acid gas; but when a quantity of lime was put into the glass vessel which contained them, they no longer continued to grow, and the leaves in a few days fell off ‡. The air, when examined, was found to contain no carbonic acid gas. The reason of this phenomenon is, that plants (as we shall see afterwards) have the power of forming and giving out carbonic acid in certain circumstances; and this quantity is sufficient to continue their vegetation for a certain time. But if this new formed gas be also withdrawn, by quicklime, for instance, which absorbs it the instant it appears, the leaves droop, and refuse to perform their functions. Carbonic acid gas, then, applied to the leaves of plants, is *essential* to vegetation.

‡ Ann. de Chim xxiv 145. 148.

147
Decompose it and emit the oxygen;

Dr Priestley, to whom we are indebted for many of the most important facts relative to vegetation, observed, in the year 1778, that plants, in certain circumstances, emitted oxygen gas ||; and Ingenhousz very soon after discovered that this gas is emitted by the *leaves* of plants, and only when they are exposed to the bright light of day. His method was to plunge the leaves of different plants into vessels full of water, and then expose them to the sun, as Bonnet, who had observed the same phenomenon, though he had given a wrong explanation of it, had done before him. Bubbles of oxygen gas very soon detached themselves from the leaves, and were collected in an inverted glass vessel *. He observed, too, that it was not a matter of indifference what kind of water was used. If the water, for instance, had been previously boiled, little or no oxygen gas escaped from the leaves; river water afforded but little gas; but pump water was the most productive of all †.

|| On Air, iii 204.

* Ingenhousz on Veget. i 15 &c.

† Ibid. 83.

Senebier proved, that if the water be previously deprived of all its air by boiling, the leaves do not emit a particle of air; that those kinds of water which yield most air, contain in them the greatest quantity of carbonic acid gas; that leaves do not yield any oxygen when plunged in water totally destitute of carbonic acid gas; that they emit it abundantly when the water, rendered unproductive by boiling, is impregnated with carbonic acid gas; that the quantity of oxygen emitted, and even its purity, is proportional to the quantity of carbonic acid gas which the water contains; that water impregnated with carbonic acid gas gradually loses the property of affording oxygen gas with leaves; and that whenever this happens, all the carbonic acid gas has disappeared; and on adding more carbonic acid gas the property is renewed ‡. These experiments prove, in a most satisfactory manner, that the oxygen gas which the leaves of plants emit depends upon the presence of carbonic acid gas; that the leaves absorb carbonic acid gas, decompose it, give out the oxygen, and retain the carbon.

‡ Enc. Methol. Phys. Veget. 181.

148
But during the day only.

We now see why plants will not vegetate without carbonic acid gas. They absorb it and decompose it; but this process goes on only when the plants are exposed to the light of day. Therefore we may conclude, that the absorption and decomposition of carbonic acid gas is confined to the day, and that light is an essential agent in the decomposition. Probably it is by its agency, or by its entering into combination with the oxygen, that this substance is enabled to assume the gaseous form, and to separate from the carbon.

If we reason from analogy, we shall conclude, that during this process a quantity of caloric [illegible]; and that therefore no increase of temperature takes place, but rather the contrary. This may be one reason why the operation takes place only during the day.

149
In this way plants may acquire much carbon.

It is extremely probable, that plants by this process acquire the greatest part of the carbonaceous matter which they contain. If we compare the quantity of carbon contained in plants vegetating in the dark, where this process cannot go on, with the quantity which those plants contain which vegetate in the usual manner, we shall perceive a very conspicuous difference. Chaptal found that a byssus, which was vegetating in the dark, contained only $\frac{1}{10}$ of its weight of carbonaceous matter; but the same plant, after being made to vegetate in the light for 30 days, contained $\frac{1}{4}$th of its weight of carbonaceous matter *. Hassenfratz ascertained, that plants growing in the dark contain much more water, and much less carbon and hydrogen, than plants growing in the light. Senebier analysed both with the same result. Plants growing in the dark yielded less hydrogen gas and oil: their resinous matter was to that of plants growing in the light as 2 to 5,5, and their moisture as 13 to 6; they contain even one-half less of fixed matters.

* Mem. Par. 1786.

It is evident, however, that this absorption and decomposition of carbonic acid gas does not depend upon the

Vegeta. the light alone. The nature of the sap has also its influence; for Hassenfratz found, that the quantity of carbon did not increase when plants vegetated in pure water. Here the sap seems to have wanted that part which combines with and retains the carbon; and which therefore is by far the most important part of the food of plants. Upon the discovery and mode of applying this substance, whatever it is, the improvements in agriculture must in a great measure depend.

If we consider the difference in the proportion of carbonaceous matter in plants vegetating in the dark and in the usual manner, we can scarcely avoid concluding that the quantity of carbonic acid gas absorbed by plants is considerable. To form an estimate of it, would require a set of experiments performed in a very different manner from any hitherto made. The stems and branches of plants vegetating in a rich soil should be confined within a large glass globe, the inside of which ought to have no communication with the external air. A very small stream of carbonic acid gas should be made occasionally to flow into this globe, so as to supply the quantity that may appear necessary; and there should be a contrivance to carry off and examine the air within the globe when it increases beyond a certain quantity. Experiments conducted in this manner would probably throw a great deal of light upon this part of vegetation, and enable us to calculate the quantity of carbonic acid decomposed, and the quantity of oxygen emitted by plants; to compare these with the waste of oxygen by the respiration of animals and combustion, and to see whether or not they balance each other.

150 The decomposition performed by the parenchyma. Senebier has ascertained, that the decomposition of the carbonic acid takes place in the parenchyma. He found, that the epidermis of a leaf would, when separated, give out no air; neither would the nerves in the same circumstances; but upon trying the parenchyma, thus separated from its epidermis and part of its nerves, it continued to give out oxygen as before †. He remarked also, that every thing else being equal, the quantity of oxygen emitted, and consequently of carbonic acid decomposed, is proportional to the thickness of the leaf; and this thickness depends upon the quantity of parenchyma.

That the decomposition is performed by peculiar organs, is evident from an experiment of Ingenhousz. Leaves cut into small pieces continued to give out oxygen as before; but leaves pounded in a mortar lost the property entirely. In the first case, the peculiar structure remained; in the other, it was destroyed. Certain experiments of Count Rumford, indeed, are totally incompatible with this conclusion; and they will naturally occur to the reader as an unsurmountable objection. He found, that dried leaves, black poplar, fibres of raw silk, and even glass, when plunged into water, gave out oxygen gas by the light of the sun. But when Senebier repeated these experiments, not one of them would succeed ‡; and we have attempted them with the same bad success. The Count must have been missed by something which he has not mentioned.

Thus we have seen, that when the sap arrives at the leaves, great part is thrown off by evaporation, and that the nature of the remainder is considerably altered by the addition of a quantity of carbon: but these are by no means all the alterations produced upon the sap in the leaves.

† Enc. Meth. Phys. Veget. 180.

‡ Ann. de Chim. i. 15.

21. Plants will not vegetate unless atmospheric air or oxygen gas have access to their leaves. This was rendered probable by those philosophers who, about the end of the 17th century, turned their attention particularly towards the physical properties of the air: But Mr Ingenhousz was perhaps the first of the modern chemists who put it beyond doubt. He found that carbonic acid gas, azot, and hydrogen gas, destroyed plants altogether, unless they were mixed with atmospheric air or oxygen gas. He found also, that plants grew very well in oxygen gas and in atmospheric air *. These experiments are sufficient to shew, that oxygen gas is necessary to vegetation. The leaves of plants seem to absorb it; and most probably this absorption takes place only in the night. We know, at least, that in germination light is injurious to the absorption of oxygen gas; and therefore it is probable that this is the case also in vegetation.

22. The leaves of plants not only absorb carbonic acid gas and oxygen gas, but water also. This had been suspected in all ages: the great effect which dew, slight showers, and even wetting the leaves of plants, have in recruiting their strength, and making them vegetate with vigour, are so many proofs that the leaves imbibe moisture from the atmosphere. Hales rendered this still more probable, by observing, that plants increase considerably in weight when the atmosphere is moist; and Mr Bonnet put the matter beyond doubt in his *Researches concerning the Use of the Leaves*. He shewed, that leaves continue to live for weeks when one of their surfaces is applied to water; and that they not only vegetate themselves, but even imbibe enough of water to support the vegetation of a whole branch, and the leaves belonging to it. He discovered also, that the two surfaces of leaves differ very considerably in their power of imbibing moisture; that in trees and shrubs, the under surface possesses almost the whole of the property, while the contrary holds in many of the other plants; the kidney bean for instance. 152 [illegible] water,

These facts prove, not only that the leaves of plants have the power of absorbing moisture, but also that the absorption is performed by very different organs from those which emit moisture; for these organs lie on different sides of the leaf. If we consider that it is only during the night that the leaves of plants are moistened with dew, we can scarcely avoid concluding, that, except in particular cases, it is during the night that plants imbibe almost all the moisture which they do imbibe.

23. During the night the leaves of plants emit carbonic acid gas. This fact was first demonstrated by Mr Ingenhousz †, and it has been since confirmed by every philosopher who has attended to the subject. 153 And emit carbonic acid gas.

Thus we have seen that the leaves of plants perform very different operations at different times. During the day they are giving out moisture, absorbing carbonic acid gas, and emitting oxygen gas; during the night, on the contrary, they are absorbing moisture, giving out carbonic acid gas, and absorbing oxygen gas.

The emission of the carbonic acid gas seems to be the consequence of the decomposition of water; either of the water which is already contained in the sap, or

* Palliau

† On Vegetables, i. 47 and 11. Palliau.

Vegetation.

of that which the leaves imbibe during the night; but which of the two, it is impossible to determine, nor is it of much consequence. We may conclude that this is the case, because it takes place during the germination of the seed, where all the circumstances seem to be perfectly analogous. The water is decomposed; its oxygen is combined with part of the carbon which had been absorbed during the day, and the hydrogen enters into new combinations in the sap. It appears, also, that this decomposition of water depends in a good measure upon the quantity of oxygen gas absorbed; for Dr Ingenhousz found, that when plants are confined in oxygen gas, they emit more carbonic acid gas than when they are confined in common air †.

† Ingenhousz ii.

154 Sap converted by these processes into the peculiar juice.

To describe in what manner these decompositions take place, is impossible; because we neither know precisely the substances into which the sap has been converted by the operations performed during the day, nor the new substances formed by the operations of the night. We only see the elementary substances which are added and subtracted; which is far from being sufficient to give us precise notions concerning the chemical changes and the affinities by which these changes are produced. We have reason, however, to conclude, that during the day the carbon of the sap is increased, and that during the night the hydrogen and oxygen are increased; but the precise new substances formed are unknown to us. Nor let any one suppose that the increase of the hydrogen, and of the oxygen of the sap, is the same thing as the addition of a quantity of water. Far from it. The substances into which the sap is converted have been enumerated in the last chapter; almost all of them consist chiefly of carbon, hydrogen, and oxygen, and yet none of them has the smallest resemblance to water. In water, oxygen and hydrogen are already combined together in a certain proportion; and this combination must be broken before these elementary bodies can enter into those triple compounds with carbon, of which a great part of the vegetable products consist. We have not the smallest conception of the manner in which these triple combinations are formed, and as little of the manner in which the bodies which compose vegetable substances are combined together. The combination may, for any thing we know to the contrary, be very complicated, though it consists only of three ingredients, and analogy leads us to suppose, that it actually is very complicated: for in chemistry it may be considered as a truth, to which at present few or no exceptions are known, that bodies are decomposed with a facility inversely as the simplicity of their composition: that is to say, that those bodies which consist of the fewest ingredients are most difficultly decomposed, and that those which are formed of many ingredients are decomposed with the greatest facility.

Neither let any one suppose, that the absorption of carbonic acid gas, during the day, is balanced by the quantity emitted during the night, and that therefore there is no increase of carbon: for Ingenhousz has shewn, that the quantity of oxygen gas emitted during the day is much greater than the carbonic acid gas emitted during the night; and that in favourable circumstances, the quantity of oxygen gas in the air surrounding plants is very much increased, and the carbonic acid gas diminished; so much so, that both Dr Priestley and Dr Ingenhousz found, that air which had been spoiled by a lighted candle, or by animals, was rendered as good as ever by plants. Now we know, that combustion and respiration diminish the oxygen gas, and add carbonic acid gas to air; therefore vegetation, which restores the purity of air altered by these processes, must increase the oxygen, and diminish the carbonic acid gas of that air: consequently the quantity of carbonic acid gas absorbed by plants during the day is greater than the quantity emitted by them during the night, and of course the carbon of the sap is increased in the leaves.

It is true, that when plants are made to vegetate for a number of days in a given quantity of air, its ingredients are not found to be altered. Thus Hassenfratz ascertained, that the air in which young chesnuts vegetated for a number of days together, was not altered in its properties, whether the chesnuts were vegetating in water or in earth *. And Saussure the Younger proved, that pease growing for ten days in water did not alter the surrounding air †. But this is precisely what ought to be the case, and what must take place, provided the conclusions which we have drawn be just. For if plants only emit oxygen gas, by absorbing and decomposing carbonic acid gas, it is evident, that unless carbonic acid gas be present, they can emit no oxygen gas; and whenever they have decomposed all the carbonic acid gas contained in a given quantity of air, we have no longer any reason to look for their emitting any more oxygen gas; and if the quantity of carbonic acid gas emitted during the night be smaller than that absorbed during the day, it is evident, that during the day the plant will constantly decompose all the acid which had been formed during the night. By these processes, the mutual changes of day and night compensate each other; and they are prevented from more than compensating each other by the forced state of the plant. It is probable, that when only part of a plant is made to vegetate in this forced state, some *carbonated sap* (if we may be allowed the expression) is supplied by the rest of the plant; and that, therefore the quantity of carbonic acid gas emitted during the night may bear a nearer proportion to that emitted in a state of nature, than that of the absorption of fixed air can possibly do. And probably, even when the whole plant is thus confined, the nightly process goes on for a certain time at the expence of the carbon already in the sap; for Hassenfratz found, that in these cases the quantity of carbon in the plant, after it had vegetated for some time in the dark, was less than it had been when it began to vegetate *. This is the reason that plants growing in the dark, when confined, absorb all the oxygen gas, and emit an equal quantity of carbonic acid gas: and whenever this has happened, they die; because then neither the daily nor nightly processes can go on.

* Ann. de Chim. xiii. 325

† Ibid. xxiv.

* Ann de Chim. xiii. 188.

24. Certain changes are also produced on the sap in the leaves by the action of light; and these changes seem to be in some measure independent, or at least different from the absorption and decomposition of carbonic acid gas, in which light, as we have seen, acts an important part.

155 Green colour of plants produced by light.

The green colour of plants is owing entirely to their vegetating in the light; for when they vegetate in the dark they are white; and when exposed to the light, they acquire a green colour in a very short time, in what-

whatſoever ſituation they are placed, even though plunged in water, provided always that oxygen be preſent; for Mr Gough has ſhewn, that light without oxygen has not the power of producing the green colour *. In what manner this change is operated, cannot, in the preſent limited ſtate of our knowledge, be aſcertained. We know too little about the properties of light to be able even to conjecture with any plauſibility. We know indeed, that part of the light is abſorbed by green plants; but this will not account for the phenomenon. When dilated, it amounts to no more than this, that plants which have grown in the dark reflect all the rays of light; while thoſe which vegetate in the light reflect the green and abſorb the others. The very mention of this phenomenon is enough to ſhew us, that we have not advanced far enough to be able to explain it.

* Manch. Memoirs, iv. 501.

Etiolated (E) plants want ſomething, or poſſeſs ſomething peculiar; and it is on this ſomething that the phenomenon depends. But what is this ſomething? The ſudden appearance of the green colour is rather againſt the ſuppoſition, that it is owing to any ſpecific change in the qualities of the ſap.

Senebier has obſerved, that when plants are made to vegetate in the dark, their etiolation is much diminiſhed by mixing a little hydrogen gas with the air that ſurrounds them *. Ingenhouſz had already remarked, that when a little hydrogen gas is added to the air in which plants vegetate, even in the light, it renders their verdure deeper †; and he ſeems to think alſo, that he has proved by experiments, that plants abſorb hydrogen gas in theſe circumſtances ‡. Mr Humbolt has obſerved, that the poa annua and compreſſa, plantago lanceolata, trifolium arvenſe, cheiranthus cheiri, lichen verticillatus, and ſeveral other plants which grow in the galleries of mines, retain their green colour even in the dark, and that in theſe caſes the air around them contains a quantity of hydrogen gas. Theſe facts are ſufficient to ſhew that there is ſome connection between the green colour of plants and the action of hydrogen gas on them; but what that connection is, it is impoſſible at preſent to ſay.

* Enc. Method Phyſ. Veget. 77.

155. By theſe different changes which go on in the leaves, the nature of the ſap is altogether changed. It is now converted into what is called the *peculiar juice*, and is fit for being aſſimilated to the different parts of the plant, and for being employed in the formation of thoſe ſecretions which are neceſſary for the purpoſes of the vegetable economy.

156 Leaves the digeſting organs of plants.

The leaves, therefore, may be conſidered as the digeſting organs of plants, and as equivalent in ſome meaſure to the ſtomach and lungs of animals. The leaves conſequently are not mere ornaments; they are the moſt important parts of the plant. Accordingly we find, that whenever we ſtrip a plant of its leaves, we ſtrip it entirely of its vegetating powers till new leaves are formed. It is well known, that when the leaves of plants are deſtroyed by inſects, they vegetate no longer, and that their fruit never makes any further progreſs in ripening, but decays and dries up. Even in germination no progreſs is made in the growth of the ſtem till the ſeed leaves appear. As much food indeed is laid up in the cotyledons as advances the plant to a certain ſtate, the root is prepared, and made ready to perform its functions; but the ſap which it imbibes muſt be firſt carried to the ſeed leaves, and digeſted there, before it be proper for forming the plumula into a ſtem. Accordingly if the ſeed leaves are cut off, the plant refuſes to vegetate.

Vegetation.

How are produced.

It will be very natural to aſk, If this be true, how come the leaves themſelves to be produced? Even if no anſwer could be given to this queſtion, it could not overturn a ſingle fact which has been formerly mentioned, nor affect a ſingle concluſion as far as it has been fairly deduced from theſe facts. We know that the leaves exiſt long before they appear; they have been traced even five years back. They are completely formed in the bud, and fairly rolled up for evolution, many months before that ſpring in which they expand. We know, too, that if we take a bud, and plant it properly, it vegetates, forms to itſelf a root, and becomes a complete plant. It will not be ſaid, ſurely, that in this caſe the bud imbibes nouriſhment from the earth; for it has to form a root before it can obtain nouriſhment in that manner; and this root cannot be formed without nouriſhment. Is not this a demonſtration that the bud contains, already laid up in itſelf, a ſufficient quantity of nouriſhment, not only to develope its own organs, but alſo to form new ones. This we conſider as a ſufficient anſwer to the objection. During the ſummer, the plant lays up a ſufficient quantity of nouriſhment in each bud, and this nouriſhment is afterwards employed in developing the leaves. This is the reaſon that the leaves make their appearance, and that they grow during the winter, when the plant is deprived of its organs of digeſtion.

Hence we ſee why the branch of a vine, if it be introduced into a hothouſe during the winter, puts forth leaves and vegetates with vigour, while every other part of the plant gives no ſigns of life. Hence alſo the reaſon that the inoculation of plants ſucceeds (F).

If a tree be deprived of its leaves, new leaves make their appearance, becauſe they are already prepared for that purpoſe: but what would be the conſequence if a tree were deprived of its leaves and of all its buds for five

(E) Plants of a white colour, from vegetating in the dark, are called *etiolated*, from a French word which ſignifies a *ſtar*, as if they grew by *ſtar light*.

(F) Hence alſo the cauſe of another well known phenomenon. The ſap flows out of trees very readily in ſpring before the leaves appear, but after that the bleeding ceaſes altogether. It is evident that there can be ſcarcely any circulation of ſap before the leaves appear; for as there is no outlet, when the veſſels are once full, they can admit no more. It appears, however, from the bleeding, that the roots are capable of imbibing, and the veſſels of circulating, the ſap with vigour. Accordingly, whenever there is an outlet, they perform their functions as uſual, and the tree bleeds; that is, they ſend up a quantity of ſap to be digeſted as uſual: but as there are no digeſting organs, it flows out, and the tree receives no injury, becauſe the ſap that flows out would not have been imbibed at all, had it not been for the artificial opening. But when the digeſtive organs appear, the tree will not bleed; becauſe theſe organs require all the ſap, and it is conſtantly flowing to them.

five years back? That plants do not vegetate without leaves, is evident from an experiment of Duhamel. He stript the bark off a tree in stripes, so as to leave five or six rings of it at some distance from each other, with no bark in the intervals. Some of these rings had buds and leaves; these increased considerably in size, but one ring which had none of these remained for years unaltered.

158 26. The peculiar juice thus formed in the leaves is carried by vessels intended for that use to all the parts of the plant, in order to be employed for the purposes of vegetation;—to increase the wood, the bark, the roots; to prepare the seeds, lay up nourishment for the buds, and to repair the decayed parts of the system, or form new ones.

If we had any method of obtaining this peculiar juice in a state of purity, the analysis of it would throw a great deal of light upon vegetation; but this is scarce possible, as we cannot extract it without dividing at the same time the vessels which contain the sap. In many cases, however, the peculiar juice may be known by its colour; and then its analysis may be performed with an approach towards accuracy. The experiments made on such juices have proved, as might have been expected, that they differ very considerably from each other, and that every plant has a juice peculiar to itself. Hence it follows, that the processes which go on in the leaves of plants must differ at least in degree, and that we have no right to transfer the conclusions deduced from experiments on one species of plants to those of another species. It is even probable, that the processes in different plants are not the same in kind; for it is not reasonable to suppose, that the phenomena of vegetation in an agaric or a boletus are precisely the same as those which take place in trees and in larger vegetables, on which alone experiments have hitherto been made.

To attempt any general account of the ingredients of the peculiar juice of plants, is at present impossible. We may conclude, however, from the experiments of Chaptal, that it contains the *vegetable fibre* of wood, either ready formed, or very nearly so; just as the blood in animals contains a substance which bears a strong resemblance to the muscular fibres.

When oxy-muriatic acid was poured into the peculiar juice of the euphorbia, which in all the species of that singular genus is of a milky colour and consistency, a very copious white precipitate fell down. This powder, when washed and dried, had the appearance of fine starch, and was not altered by keeping. It was neither affected by water nor alkalies. Alcohol, assisted by heat, dissolved two thirds of it; which were again precipitated by water, and had all the properties of resin. The remaining third part possessed the properties of the *woody fibre*. Mr Chaptal tried the same experiment on the juices of a great number of other plants, and he constantly found that oxy-muriatic acid precipitated from them *woody fibre*. The seeds of plants exhibited exactly the same phenomenon; and a greater quantity of woody fibre was obtained from them than from an equal portion of the juices of plants *. These experiments are sufficient to shew, that the proper juices of plants contain their nourishment ready prepared, nearly in the state in which it exists in the seed for the use of the young embryo.

* Ann. de Chim. xxi. 285.

The peculiar juices of plants, then, contain more carbon, hydrogen, and oxygen, and less water, and probably lime also, than the sap. They are conveyed to every part of the plant; and all the substances which we find in plants, and even the organs themselves, by which they perform their functions, are formed from them. But the thickest veil covers the whole of these processes; and so far have philosophers hitherto been from removing this veil, that they have not even been able to approach it. All these operations, indeed, are evidently chemical decompositions and combinations; but we neither know what these decompositions and combinations are, nor the instruments in which they take place, nor the agents by which they are regulated.

Vegetation.

159 Its uses.

160 Plants decay and die.

27. Such, as far as we are acquainted with them, are the changes produced by vegetation. But plants do not continue to vegetate for ever; sooner or later they decay, and wither, and rot, and are totally decomposed. This change indeed does not happen to all plants at the end of the same time. Some live only for a single season, or even for a shorter period; others live two seasons, others three, others a hundred or more; and there are some plants which continue to vegetate for a thousand years. But sooner or later they all cease to live; and then those very chemical and mechanical powers which had promoted vegetation combine to destroy the remains of the plant. Now, What is the cause of this change? Why do plants die?

This question can only be answered by examining with some care what it is which constitutes the *life* of plants; for it is evident, that if we can discover what that is which constitutes the life of a plant, it cannot be difficult to discover what constitutes its death.

161 Phenomena of vegetable life.

Now the phenomena of vegetable life are in general called *vegetation*. As long as a plant continues to vegetate, we say that it lives; when it ceases to vegetate, we conclude that it is dead.

The life of vegetables, however, is not so intimately connected with the phenomena of vegetation, that they cannot be separated. Many seeds may be kept for years without giving any symptom of vegetation; yet if they vegetate when put into the earth, we say that they possess life; and if we would speak accurately, we must say also, that they possessed life even before they were put into the earth; for it would be absurd to suppose that the seed *acquired* life merely by being put into the earth. In like manner, many plants decay, and give no symptoms of vegetation during winter; yet if they vegetate when the mild temperature of spring affects them, we consider them as having lived all winter. The life of plants, then, and the phenomena of vegetation, are not precisely the same thing; for the one may be separated from the other, and we can even suppose the one to exist without the other. Nay, what is more, we can, in many cases, *decide*, without hesitation, that a vegetable is not dead, even when no vegetation appears; and the proof which we have for its life is, that it *remains unaltered*; for we know that when a vegetable is dead, it soon changes its appearance, and falls into decay.

Thus it appears that the *life* of a vegetable consists in two things. 1. In remaining unaltered, when circumstances are unfavourable to vegetation; 2. In exhibiting

Vegetation. hibiting the phenomena of vegetation when circumstances are favourable. When neither of these two things happens, we say that a vegetable is dead.

The phenomena of vegetation have been enumerated above. They consist in the formation or expansion of the organs of the plant, in the taking in of nourishment, in carrying it to the leaves, in digesting it, in distributing it through the plant, in augmenting the bulk of the plant, in repairing decayed parts, in forming new organs when they are necessary, in producing seeds capable of being converted into plants similar to the parent. The *cause* of these phenomena, whatever it may be, is the *cause* also of *vegetable life*.

All the substances which have been enumerated in the first part of the article CHEMISTRY, *Suppl.* together with their compounds and component parts, possess certain qualities in common; in consequence of which, a term has been invented which includes them all. This term is *matter*. Now these common qualities may all ultimately be resolved into certain attractions and repulsions which these substances exert. These qualities may be said, without any impropriety, to be *essential to matter*; because every body to which we give the name of *matter* possesses them; and if any body were to be deprived of these qualities, it could no longer be included under the denomination *matter*. In short, the word *matter* comprehends under it certain qualities; every substance which possesses these qualities is called *matter*; and no other substance except these can receive the name of *matter* without altering the meaning of the word.

162 Not reducible to the laws of matter. The attractions and repulsions of matter have been examined with care; and the changes which they produce have been ascertained with considerable accuracy. They have even been reduced to general principles under the name of [illegible]. Whenever any change is observed, if that change be a result of a mechanical or chemical law, we say that the agent is *matter*; but if [illegible] these laws, or if it be incompatible with these laws, we must say, unless we would pervert the meaning of words altogether, that the agent is not *matter*.

Now it cannot be disputed [illegible] the phenomena of life in vegetables [illegible] with the laws of mechanics and chemistry. The motion of the sap, for instance, [illegible] the contraction of the vessels; and the contraction of vessels, on the application of stimuli, is incompatible with the laws of chemistry, because no decomposition takes place; and of mechanics, because a much greater force is generated than the generating body itself possessed. The evolution of the organs of vegetables, the reparation of decayed organs, the formation of new ones to supply the place of the old, the production of seeds capable of producing new plants, the constant similarity of individuals of the same species;—these, and many other well known phenomena, cannot be reduced under mechanical and chemical laws. The cause of life, then, in plants, is a *substance* (for we can form no conception of an agent which is not a substance) which does not act according to the laws of mechanics and chemistry,

163 Consequently owing to an immaterial cause.

and which consequently is *not matter*. We shall therefore, till a better name be chosen, denominate it the *vegetative principle* (G).

164 Nature of the vegetative principle. The nature of the *vegetative principle* can only be deduced from the phenomena of vegetation. It evidently follows a fixed plan, and its actions are directed to promote the good of the plant. It has a power over matter, and is capable of directing its attraction and repulsions, in such a manner as to render them the instruments of the formation, and improvement, and preservation of the plant. It is capable also of generating substances endowed with powers similar to itself. The plan according to which it acts, displays the most consummate wisdom and foresight, and a knowledge of the properties of matter infinitely beyond what man can boast.

165 Whether endowed with consciousness. Metaphysicians have thought proper to divide all substances into two classes, *matter* and *mind*. If we follow this division, the vegetative principle, as it is not *material*, must undoubtedly be ranked under *mind*. But if *consciousness* and *intelligence* be considered as essential to mind, which is the case according to their definition, we cannot give the vegetative principle the name of *mind*, because it has not been proved that it possesses consciousness and intelligence. It acts indeed according to a fixed plan, which displays the highest degree of intelligence; but this plan may belong, not to the vegetative principle itself, but to the Being who formed that principle. We can conceive it to have been endowed by the Author of Nature with peculiar powers, which it must always exert according to certain fixed laws; and the phenomena of vegetation *may be* the result of this mode of acting. This, as far as we can see, is not impossible. It must be shewn to be impossible by every person who wishes to prove that plants possess consciousness and intelligence; for the proofs of that consciousness can only be deduced from the design which the actions of plants manifest. Those philosophers who have ascribed consciousness and intelligence to plants, have founded their belief principally on certain actions which plants perform on the application of stimuli. But these actions prove nothing more than what cannot be denied, that there exists a vegetative principle, which is not material, and which has certain properties in common with the living principles of animals; but whether or not this vegetative principle possesses consciousness and intelligence, is a very different question, and must be decided by very different proofs. We do not say that the heart of an animal is conscious, because it continues to beat on the application of proper stimuli for some time after it has been separated from the rest of the body.

166 Death of plants. The death of plants, if we can judge from the phenomena, is owing, not to the vegetative principle leaving them, but to the organs becoming at last altogether unfit for performing their functions, and incapable of being repaired by any of the powers which that principle possesses. The changes which vegetable substances undergo after death come now to be examined. They shall form the subject of the ensuing chapter.

CHAP.

(G) Physiologists have usually given it the name of *living principle*. We would have adopted that name, if it had not been too general for our purpose.

CHAP. III. OF THE DECOMPOSITION OF VEGETABLE SUBSTANCES.

NOT only entire plants undergo decompofition after death, but certain vegetable fubftances alfo, whenever they are mixed together, and placed in proper circumftances, mutually decompofe each other, and new com-
167 Vegetable decompofitions, pound fubftances are produced. These mutual decompofitions, indeed, are naturally to be expected: for as all vegetable fubftances are compofed of feveral ingredients, differing in the ftrength of their affinity for each other, it is to be fuppofed that, when two fuch fubftances are mixed together, the divellent affinities will, in many cafes, prove ftronger than the quiefcent; and therefore decompofition, and the formation of new compounds, muft take place: juft as happens when the acetite of lead and fulphat of potafs are mixed together.

Thefe mutual decompofitions of vegetable fubftances are by no means fo eafily traced, or fo readily explained, as the mutual decompofitions of neutral falts; partly on account of the number of fubftances, whofe affinities for each other are brought into action, and partly becaufe we are ignorant of the manner in which the ingredients of vegetable fubftances are mutually combined.

168 Called FERMENTATION. Chemifts have agreed to give thefe mutual decompofitions which take place in vegetable fubftances the name of *fermentation*; a word firft introduced into chemiftry by Van Helmont *; and the new fubftances produced they have called the *products* of fermentation. All the phenomena of fermentation lay for many years concealed in the completeft darknefs, and no chemift was bold enough to hazard even an attempt to explain them. They were employed, however, and without hefitation too, in the explanation of other phenomena; as if giving to one procefs, the name of another of which we are equally ignorant, could, in reality, add any thing to our knowledge. The darknefs which enveloped thefe phenomena, has lately begun to difperfe; but they are ftill furrounded with a very thick mift; and we muft be much better acquainted with the compofition of vegetable fubftances, and the mutual affinities of their ingredients, than we are at prefent, before we can explain them in a fatisfactory manner.

* *Stahl, Fundament Chem.* i. 224.

169 Division of them. The vegetable fermentations or decompofitions may be arranged under five heads; namely, that which produces *bread*, that which produces *wine*, that which produces *beer*, that which produces *acetous acid* or *vinegar*, and the *putrefactive* fermentation, or that which produces the fpontaneous decompofition of decayed vegetables. Thefe fhall be the fubject of the five following fections. In order to avoid long titles, we fhall give to the firft three fections the name of the new fubftances produced by the fermentation.

SECT. I. *Of Bread.*

170 Difcovery of bread. SIMPLE as the manufacture of bread may appear to us who have been always accuftomed to confider it as a common procefs, its difcovery was probably the work of ages, and the refult of the united efforts of men, whofe fagacity, had they lived in a more fortunate period of fociety, would have rendered them the rivals of Ariftotle or of Newton.

The method of making bread fimilar to ours was known in the Eaft at a very early period; but neither the precife time of the difcovery, nor the name of the perfon who publifhed it to the world, has been preferved. We are certain that the Jews were acquainted with it in the time of Mofes: for in Exodus * we find a prohibition to ufe leavened bread during the celebration of the paffover. It does not appear, however, to have been known to Abraham; for we hear in his hiftory of cakes frequently, but nothing of leaven. Egypt, both from the nature of the foil and the early period at which it was civilized, bids faireft for the difcovery of making bread. It can fcarcely be doubted, that the Jews learned the art from the Egyptians The Greeks affure us, that they were taught the art of making bread by the god Pan. We learn from Homer that it was known during the Trojan war †. The Romans were ignorant of the method of making bread till the year 580, after the building of Rome, or 200 years before the commencement of the Chriftian era ‡. Since that period the art has never been unknown in the fouth of Europe; but it made its way to the north very flowly, and even at prefent in many northern countries fermented bread is but very feldom ufed.

* Ch. xii. v. 15.

† *Iliad*, ix. 216.

‡ *Plin.* l. xviii. cap. 11.

The only fubftance well adapted for making bread, we mean *loaf bread*, is wheat flour, which is compofed of four ingredients; namely, gluten, ftarch, albumen, and a *fweet mucous matter*, which poffeffes nearly the properties of fugar, and which is probably a mixture of fugar and mucilage. It is to the gluten that wheat flour owes its fuperiority to every other as the bafis of bread. Indeed, there are only two other fubftances at prefent known of which good loaf bread can be made; thefe are *rye* and *potatoes*. The rye loaf is by no means fo well raifed as the wheat loaf; and potatoes will not make bread at all without particular management. Potatoes, previoufly boiled and reduced to a very fine tough pafte by a rolling pin, muft be mixed with an equal weight of potato ftarch. This mixture, baked in the ufual way, makes a very white, well raifed, pleafant bread. We are indebted for the procefs to Mr Permentier. Barley-meal perhaps might be fubftituted for ftarch. — 171 Subftance which make bread.

The baking of bread confifts in mixing wheat flour with water, and forming it into a pafte. The average proportion of thefe is two parts of water to three of flour. But this proportion varies confiderably, according to the age and the quality of the flour. In general, the older and the better the flour is, the greater is the quantity of water required. If the pafte, after being thus formed, be allowed to remain for fome time, its ingredients gradually act upon each other, and the pafte acquires new properties. It gets a difagreeable four tafte, and a quantity of gas (probably carbonic acid gas) is evolved. In fhort, the pafte ferments (H). Thefe changes do not take place without water; that liquid, therefore, is a neceffary agent. Poffibly it is decompofed by the action of the ftarch upon it; for when ftarch is diluted with water, it gradually becomes four. The gluten, too, is altered, either by the action of the water on it, or of the ftarch; for if we examine the pafte after — 172 Baking of bread.

(H) It was from this procefs that Van Helmont transferred the word *fermentation* into chemiftry.

Bread.

after it has undergone fermentation, the gluten is no longer to be found. If paste, after standing for a sufficient time to ferment, be baked in the usual way, it forms a loaf full of eyes like our bread, but of a taste so sour and unpleasant that it cannot be eaten. If a small quantity of this old paste, or *leaven* as it is called, be mixed with new made paste, the whole begins to ferment in a short time; a quantity of gas is evolved; but the glutinous part of the flour renders the paste so tough, that the gas cannot escape; it therefore causes the paste to swell in every direction: and if it be now baked into loaves, the immense number of air bubbles imprisoned in every part renders the bread quite full of eyes, and very light. If the precise quantity of leaven necessary to produce the fermentation, and no more, has been used, the bread is sufficiently light, and has no unpleasant taste; but if too much leaven be employed, the bread has a bad taste; if too little, the fermentation does not come on, and the bread is too compact and heavy. To make good bread with leaven, therefore, is very difficult.

The ancient Gauls had another method of fermenting bread. They formed their paste in the usual way; and instead of leaven, mixed with it a little of the *barm* which collects on the surface of fermenting beer*. This mixture produced as complete and as speedy a fermentation as leaven; and it had the great advantage of not being apt to spoil the taste of the bread. About the end of the 17th century, the bakers in Paris began to introduce this practice into their processes. The practice was discovered, and exclaimed against; the faculty of medicine, in 1688, declared it prejudicial to health; and it was not till after a long time that the bakers succeeded in convincing the public that bread baked with *barm* is superior to bread baked with leaven. In this country the bread has for these many [illegible]

What is the barm which produces these effects? The question is curious and important; but we are not able to answer it completely. Mr Henry of Manchester has concluded, from a number of very interesting experiments, that the only useful part of barm is carbonic acid gas, and that this gas therefore is the real fermenter of paste ‡.

‡ Manch. Mem. ii. 262.

That the barm of beer, in its usual state, contains carbonic acid gas, cannot be doubted; and that carbonic acid gas acts as a ferment, the experiments of Mr Henry prove decisively. But that the only active part of barm is carbonic acid gas, and nothing but carbonic gas, is extremely doubtful, or rather we are certain that it is not true. It has been customary with the bakers of Paris to bring their barm from Flanders and Picardy in a state of dryness. When skimmed off the beer, it is put into sacks, and the moisture allowed to drop out; then these sacks are subjected to a strong pressure, and when the barm is dry it is made up into balls †. Now, in this state, it is not to be supposed that bubbles of carbonic acid can remain entangled in the barm; they must have been squeezed out by the press, and by the subsequent formation of the barm into balls: yet this barm, when moistened with water, ferments the bread as well as new barm.

† Enc. Meth. t. i. 249.

Bread.

171 Heat of the oven.

After the bread has fermented, and is properly raised, it is put into the oven previously heated, and allowed to remain till it be baked. The mean heat of an oven, as ascertained by Mr Tillet, is 448°*. The bakers do not use a thermometer; but they judge that the oven is arrived at the proper heat when flour thrown on the floor of it becomes black very soon without taking fire. We see, from Tillet's experiment, that this happens at the heat of 448°.

* Enc. Meth. ii. 275.

172 Loss of weight sustained in it.

When the bread is taken out of the oven, it is found to be lighter than when put in; as might naturally have been expected, from the evaporation of moisture, which must have taken place at that temperature. Mr Tillet, and the other commissioners who were appointed to examine this subject in consequence of a petition from the bakers of Paris, found that a loaf, which weighed before it was put into the oven 4.625 lbs. after being taken out baked, weighed, at an average, only 3.813 lbs. or 0.812 lb. less than the paste. Consequently 100 parts of paste lose, at an average, 17.34 parts, or somewhat more than $\frac{1}{6}$th by baking*. They found, however, that this loss of weight was by no means uniform, even with respect to those loaves which were in the oven at the same time, of the same form, and in the same place, and which were put in and taken out at the same instant. The greatest difference in these circumstances amounted to .2889, or 7.5 parts in the hundred, which is about $\frac{1}{13}$th of the whole. This difference is very considerable, and it is not easy to say to what it is owing. It is evident, that if the paste has not all the same degree of moisture, and if the barm be not accurately mixed through the whole, if the fermentation of the whole be not precisely the same, that these differences must take place. Now it is needless to observe how difficult it is to perform all this completely. The French commissioners found, as might indeed have been expected, that other things being equal, the loss of weight sustained is proportional to the extent of surface of the loaf, and to the length of time that it remains in the oven; that is to say, the smaller the extent of the external surface, or, which is the same thing, the nearer the loaf approaches to a globular figure, the smaller is the loss of weight which it sustains; and the longer it continues in the oven, the greater is the loss of weight which it sustains. Thus a loaf which weighed exactly 4 lbs. when newly taken out of the oven, being replaced as soon as weighed, lost, in ten minutes, .125 lb. of its weight, and in ten minutes more it again lost .0625 lb †.

* Ibid. 275

† Ibid. p. 276.

Loaves are heaviest when just taken out of the oven; they gradually lose part of their weight, at least if not kept in a damp place, or wrapt round with a wet cloth (x). Thus Mr Tillet found that a loaf of 4 lbs. after being kept for a week, wanted .3125, or nearly $\frac{1}{13}$th of its original weight ‡.

‡ Ibid.

Properties of bread.

When bread is newly taken out of the oven, it has a peculiar, and rather pleasant smell, which it loses by keeping; as it does also the peculiar taste by which new bread is distinguished. This shews us, that the bread undergoes chemical changes; but what these changes are, or what the peculiar substance is to which the odour of bread is owing, is not known.

(x) This is an excellent method of preserving bread fresh, and free from mould, for a long time.

Wine. Bread differs very completely from the flour of which it is made. for none of the ingredients of the flour can now be discovered in it. The only chemist who has attempted an analysis of bread is Mr Geoffroy. He found that 100 parts of bread contained the following ingredients :

24.735	water.
32.030	gelatinous matter, extracted by boiling water.
39.843	residuum insoluble in water.
96.608	
3.392	loss.
100.	

But this analysis, which was published in the Memoirs of the French Academy for the year 1732, was made at a time when the infant state of the science of chemistry did not admit of any thing like accuracy.

SECT. II. *Of WINE.*

177 Fruits affording wine. THERE is a considerable number of ripe fruits from which a sweet liquor may be expressed, having at the same time a certain degree of acidity. Of such fruits we have in this country the apple, the cherry, the gooseberry, the currant, &c. but by far the most valuable of these fruits is the *grape*, which grows luxuriantly in the southern parts of Europe. From grapes, fully ripe, may be expressed a liquid of a sweet taste, to which the name of *must* has been given. This liquid is composed almost entirely of five ingredients; namely, *water*, *sugar*, *jelly*, *mucilage*, and *tartarous* acid partly saturated with potass. The quantity of sugar which grapes fully ripe contain is very considerable; it may be obtained in crystals by evaporating must to the consistence of syrup, separating the tartar which precipitates during the evaporation, and then setting the must aside for some months. The crystals of sugar are gradually formed.

178 Undergo the vinous fermentation; When must is put into the temperature of about 70°, the different ingredients begin to act upon each other, and what is called *vinous fermentation* commences. The phenomena of this fermentation are an intestine motion in the liquid, its becoming thick and muddy, a temperature equal to 72.5°, and an evolution of carbonic acid gas. In a few days the fermentation ceases, the thick part subsides to the bottom, the liquid becomes clear, it has lost much of its saccharine taste, and assumed a new one, its specific gravity is diminished; and, in short, it has become the liquid well known under the name of *wine*.

Now what is the cause of this fermentation; what are the substances which mutually decompose each other; and what is the nature of the new substance formed?

These changes are produced altogether by the mutual action of the substances contained in must; for they take place equally well, and wine is formed equally well in close vessels as in the open air §.

179 For which water, If the *must* be evaporated to the consistency of a thick syrup, or to a *rob*, as the elder chemists termed it, the fermentation will not commence, though the proper temperature, and every thing else necessary to produce fermentation, be present ‖. But if this syrup be again diluted with water, and placed in favourable circumstances, it will ferment. Therefore the presence of *water* is absolutely necessary for the existence of vinous fermentation.

180 Sugar, If the juice of those fruits which contain but little sugar, as currants, be put into a favourable situation, fermentation indeed takes place, but so slowly, that the product is not *wine*, but *vinegar*: but if a sufficient quantity of sugar be added to these very juices, wine is readily produced. No substance whatever can be made to undergo vinous fermentation, and to produce wine, unless sugar be present. *Sugar* therefore is absolutely necessary for the existence of vinous fermentation; and we are certain that it is decomposed during the process; for no sugar can be obtained from properly fermented wine.

181 An acid, All those juices of fruits which undergo the vinous fermentation, either with or without the addition of sugar, contain an acid. We have seen already in the first chapter that the vegetable acids are obtained chiefly from fruits. The apple, for instance, contains malic acid; the lemon, citric acid; the grape, tartarous acid. The Marquis de Bullion has ascertained, that *must* will not ferment if all the tartarous acid which it contains be separated from it*. We may conclude from this, that the presence of a vegetable acid is absolutely necessary for the commencement of the vinous fermentation. This renders it probable that the essential part of barm is a vegetable acid, or something equivalent; for if sugar be dissolved in four times its weight of water, mixed with the yeast of beer, and placed in a proper temperature, it undergoes the vinous fermentation †.

182 And jelly are necessary. All the juices of fruits which undergo the vinous fermentation contain a quantity of jelly, or mucilage, or of both. These two substances resemble each other in so many particulars, and it is so difficult to separate them, that we shall suppose they have the same effect in the mixture. The presence of these substances renders it probable that they also are necessary for the vinous fermentation. Perhaps they act chiefly by their tendency to become acid.

Thus we see, that for the production of wine a certain temperature, a certain portion of water, sugar, a vegetable acid, and, in all probability, jelly also, is necessary. Mr Lavoisier found that sugar would not ferment unless dissolved in at least four times its weight of water. This seems to indicate that the particles of sugar must be removed to a certain distance from each other before the other ingredients can decompose them. The evolution and separation of carbonic acid gas in such quantity, shews us that the proportion of the carbon and the oxygen of the sugar is diminished. It is not certain that the mucilage of the wine is decomposed so completely as the sugar; for it has been observed, that when the must abounds in mucilage, the wine is apt to become sour.

183 Decomposition of wine. When wine is distilled by means of a low heat, there comes over a quantity of *alcohol*, and the remainder is a solution of acetous acid. From this fact, it has been concluded that wine is composed of acetous acid and alcohol. But that the distillation occasions a chemical change in the ingredients of wine is evident from this, that if we again mix the alcohol and acetous acid, we do not reproduce the wine.

Fourcroy has attempted to shew that alcohol existed ready formed; but his proofs are not conclusive. Fabroni

§ *Fabroni, Ann. de Chim.* xxxi. 302.

‖ *Stahl*, i.

* *Chaptal*

† *Bergman*

Beer. rom has shewn, that alcohol cannot be obtained from new made wine by any other method than distillation. When wine is satured with very dry carbonat of potash, no alcohol makes its appearance on the surface of the mixture, yet a very small quantity of alcohol, artificially mixed with wine, may be detected by this method. It is certain, however, that alcohol exists ready formed in old wine.

SECT. III. *Of Beer.*

THE method of making beer was known in the most remote ages; we are ignorant to whom the world is indebted for the discovery of it. Beer is usually made from *barley*.

184 Method of making malt, The barley is steeped in water for about sixty hours, in order to saturate it with that liquid. It ought then to be removed as speedily as possible, otherwise the water dissolves, and carries off the most valuable part of the grain. The barley is then to be laid in a heap for twenty-four hours; heat is evolved, oxygen gas absorbed, carbonic acid gas emitted, and germination commences with the shooting forth of the radicle. It is then spread upon a cool floor, dried slowly, and is afterwards known by the name of *malt* *.

185 Wort, Malt, previously ground to a coarse powder, is to be infused in a sufficient quantity of pure water, of the temperature of 160°, for an hour. The infusion is then to be drawn off, and more water may be added, at a higher temperature, till all the soluble part of the malt is extracted. This infusion is known by the name of *wort*. It has a sweet taste, and contains a quantity of saccharine, and doubtless also of gelatinous matter.

186 And beer. When *wort* is placed in the temperature of about 60°, fermentation gradually takes place in it, and the very same phenomena [illegible] th the production of wine. T[illegible] of wort, then, is nothing but a particular [illegible] vinous fermentation. But wort does [illegible] well, nor so soon, nor does it [illegible] of good for [illegible] to it. The reason of [illegible] itation does not commence [illegible] wort, and before this happens part [illegible] contents are decomposed; whereas the [illegible] d, or, at least, something [illegible]

Wort ferments in [illegible] as Mr Collier ascertained by experiment, equally well as in the open air. Therefore the decomposition is produced entirely by the substances contained in the wort, without the addition of any thing from the air. The quantity of beer produced in close vessels is much greater than when the process takes place in the open air. The reason of which is, that in the open air the beer gradually evaporates during the fermentation. Thus Mr Collier found that 11 quarts, 3½ oz. fermented in open vessels, lost, in 12 days, 40 oz.; whereas an equal weight, fermented in close vessels, lost only 8 oz. in the same time. Yet the quality of the *beer* was the same in each; for equal quantities of both, when distilled, yielded precisely the same portion of alcohol †.

Acetous Fermentation, Putrefaction. During the fermentation, a quantity of carbonic acid gas is constantly disengaged, not in a state of purity, but containing, combined with it, a portion of the wort; and if this gas be made to pass through water, it will deposite wort, which may be fermented in the usual manner *.

When beer is distilled, alcohol is obtained, and the residuum is an acid liquor †. The theory of beer is so obviously the same with that of wine that it requires no additional explanation.

SECT. IV. *Of the Acetous Fermentation.*

187 Substances which undergo the acetous fermentation. IF wine or beer be kept at a temperature between 70° and 90°, it gradually loses its properties, and is converted into *acetous acid*.

During this change, a quantity of oxygen gas is absorbed, and the whole of the spirituous part of the wine or beer disappears. Consequently its ingredients have mutually decomposed each other.

Neither pure alcohol, nor alcohol diluted with water, are capable of undergoing this change, neither do they absorb any oxygen. This absorption, then, is made by the mucilaginous matter which always exists in these liquids. No acetous acid is ever produced, unless some acid be present in the liquid. We may conclude, then, that the mucilage acquires the properties of an acid before it begins to act upon the spirituous part of the beer or the wine.

As the acetous acid has been already treated of in the article CHEMISTRY, *Suppl.* it is unnecessary to dwell any longer on this subject here.

SECT. V. *Of Putrefaction.*

188 Nature of putrefaction. ALL vegetable substances, both complete plants and their component parts separately, when left entirely to themselves, are gradually decomposed and destroyed, provided moisture be present, and the temperature be not much under 45°, nor too high to evaporate suddenly all the moisture. This decomposition has obtained the name of *putrefaction*.

It proceeds with most rapidity in the open air; but the contact of air is not absolutely necessary. Water is, in all cases, essential to the process, and therefore is most probably decomposed.

Putrefaction is constantly attended with a fetid odour, owing to the emission of certain gaseous matters, which differ according to the putrefying substance. Some vegetable substances, as gluten, and cruciform plants, emit ammonia; others, as onions, seem to emit phosphorated hydrogen gas. Carbonic acid gas, and hydrogen gas, impregnated with unknown vegetable matters, are almost constantly emitted in abundance. When the whole process is finished, scarcely any thing remains but the earths, the salts, and the metals, which formed a constituent part of the vegetable. But our chemical knowledge of vegetable compounds is by far too limited to enable us to follow this very complicated process with any chance of success.

† Ibid. [illegible] Mem. [illegible]

Wine.

Bread differs very completely from the flour of which it is made. for none of the ingredients of the flour can now be discovered in it. The only chemist who has attempted an analysis of bread is Mr Geoffroy. He found that 100 parts of bread contained the following ingredients:

24.735 water.
32.030 gelatinous matter, extracted by boiling water.
39.843 residuum insoluble in water.

96.608
3.392 loss.

100.

But this analysis, which was published in the Memoirs of the French Academy for the year 1732, was made at a time when the infant state of the science of chemistry did not admit of any thing like accuracy.

Sect. II. *Of Wine.*

177 Fruits affording wine

There is a considerable number of ripe fruits from which a sweet liquor may be expressed, having at the same time a certain degree of acidity. Of such fruits we have in this country the apple, the cherry, the gooseberry, the currant, &c. but by far the most valuable of these fruits is the *grape*, which grows luxuriantly in the southern parts of Europe. From grapes, fully ripe, may be expressed a liquid of a sweet taste, to which the name of *must* has been given. This liquid is composed almost entirely of five ingredients; namely, *water*, *sugar*, *jelly*, *mucilage*, and *tartarous* acid partly saturated with potass. The quantity of sugar which grapes fully ripe contain is very considerable; it may be obtained in crystals by evaporating must to the consistence of syrup, separating the tartar which precipitates during the evaporation, and then setting the must aside for some months. The crystals of sugar are gradually formed.

178 Undergo the vinous fermentation;

When must is put into the temperature of about 70°, the different ingredients begin to act upon each other, and what is called *vinous fermentation* commences. The phenomena of this fermentation are an intestine motion in the liquid, its becoming thick and muddy, a temperature equal to 72.5°, and an evolution of carbonic acid gas. In a few days the fermentation ceases, the thick part subsides to the bottom, the liquid becomes clear, it has lost much of its saccharine taste, and assumed a new one, its specific gravity is diminished; and, in short, it has become the liquid well known under the name of *wine*.

Now what is the cause of this fermentation; what are the substances which mutually decompose each other; and what is the nature of the new substance formed?

These changes are produced altogether by the mutual action of the substances contained in must; for they take place equally well, and wine is formed equally well in close vessels as in the open air §.

§ Fabroni, Ann. de Chim. xxxi. 302.

179 For which water,

If the *must* be evaporated to the consistency of a thick syrup, or to a *rob*, as the elder chemists termed it, the fermentation will not commence, though the proper temperature, and every thing else necessary to produce fermentation, be present ||. But if this syrup be again diluted with water, and placed in favourable circumstances, it will ferment. Therefore the presence of *water* is absolutely necessary for the existence of vinous fermentation.

|| Stahl, i.

180 Sugar,

If the juice of those fruits which contain but little sugar, as currants, be put into a favourable situation, fermentation indeed takes place, but so slowly, that the product is not *wine*, but *vinegar*: but if a sufficient quantity of sugar be added to these very juices, wine is readily produced. No substance whatever can be made to undergo vinous fermentation, and to produce wine, unless sugar be present. *Sugar* therefore is absolutely necessary for the existence of vinous fermentation; and we are certain that it is decomposed during the process; for no sugar can be obtained from properly fermented wine.

181 An acid,

All those juices of fruits which undergo the vinous fermentation, either with or without the addition of sugar, contain an acid. We have seen already in the first chapter that the vegetable acids are obtained chiefly from fruits. The apple, for instance, contains malic acid; the lemon, citric acid; the grape, tartarous acid. The Marquis de Bullion has ascertained, that *must* will not ferment if all the tartarous acid which it contains be separated from it*. We may conclude from this, that the presence of a vegetable acid is absolutely necessary for the commencement of the vinous fermentation. This renders it probable that the essential part of barm is a vegetable acid, or something equivalent; for if sugar be dissolved in four times its weight of water, mixed with the yeast of beer, and placed in a proper temperature, it undergoes the vinous fermentation †.

* Chaptal.

† Bergman.

182 And jelly, are necessary.

All the juices of fruits which undergo the vinous fermentation contain a quantity of jelly, or mucilage, or of both. These two substances resemble each other in so many particulars, and it is so difficult to separate them, that we shall suppose they have the same effect in the mixture. The presence of these substances renders it probable that they also are necessary for the vinous fermentation. Perhaps they act chiefly by their tendency to become acid.

Thus we see, that for the production of wine a certain temperature, a certain portion of water, sugar, a vegetable acid, and, in all probability, jelly also, is necessary. Mr Lavoisier found that sugar would not ferment unless dissolved in at least four times its weight of water. This seems to indicate that the particles of sugar must be removed to a certain distance from each other before the other ingredients can decompose them. The evolution and separation of carbonic acid gas in such quantity, shews us that the proportion of the carbon and the oxygen of the sugar is diminished. It is not certain that the mucilage of the wine is decomposed so completely as the sugar; for it has been observed, that when the must abounds in mucilage, the wine is apt to become sour.

183 Decomposition of wine.

When wine is distilled by means of a low heat, there comes over a quantity of *alcohol*, and the remainder is a solution of acetous acid. From this fact, it has been concluded that wine is composed of acetous acid and alcohol. But that the distillation occasions a chemical change in the ingredients of wine is evident from this, that if we again mix the alcohol and acetous acid, we do not reproduce the wine.

Fourcroy has attempted to shew that alcohol existed ready formed; but his proofs are not conclusive. Fab-

roni

Begr. roni has shewn, that alcohol cannot be obtained from new made wine by any other method than distillation. When wine is satured with very dry carbonat of potass, no alcohol makes its appearance on the surface of the mixture, yet a very small quantity of alcohol, artificially mixed with wine, may be detected by this method. It is certain, however, that alcohol exists ready formed in old wine.

Sect. III. *Of Beer.*

The method of making beer was known in the most remote ages; we are ignorant to whom the world is indebted for the discovery of it. Beer is usually made from *barley*.

184 Method of making malt, The barley is steeped in water for about sixty hours, in order to saturate it with that liquid. It ought then to be removed as speedily as possible, otherwise the water dissolves, and carries off the most valuable part of the grain. The barley is then to be laid in a heap for twenty-four hours; heat is evolved, oxygen gas absorbed, carbonic acid gas emitted, and germination commences with the shooting forth of the radicle. It is then spread upon a cool floor, dried slowly, and is afterwards known by the name of *malt* *.

Malt, previously ground to a coarse powder, is to be infused in a sufficient quantity of pure water, of the temperature of 160°, for an hour. The infusion is then to be drawn off, and more water may be added, at a higher temperature, till all the soluble part of the malt is extracted. This infusion is known by the name of *wort*. It has a sweet taste, and contains a quantity of saccharine, and doubtless also of gelatinous matter.

185 Wort,

186 And beer. When *wort* is placed in the temperature of about 60°, fermentation gradually takes place in it, and the very same phenomena appear which distinguish the production of wine. The fermentation of wort, then, is nothing but a particular case of the vinous fermentation. But [illegible] well, nor so soon, nor does [illegible] a quantity of good fermented [illegible] is added to it. The reason of [illegible] ntation does not [illegible] an acid [illegible] wort, and [illegible] part [illegible] contents are decomposed; whereas [illegible] d, or, at least, something equivalent [illegible]

Wort ferments in [illegible] as Mr Collier ascertained by experiment, equally well as in the open air. Therefore the decomposition is produced entirely by the substances contained in the wort, without the addition of any thing from the air. The quantity of beer produced in close vessels is much greater than when the process takes place in the open air. The reason of which is, that in the open air the beer gradually evaporates during the fermentation. Thus Mr Collier found that 11 quarts, $3\frac{1}{2}$ oz. fermented in open vessels, lost, in 12 days, 40 oz.; whereas an equal weight, fermented in close vessels, lost only 8 oz. in the same time. Yet the quality of the *beer* was the same in each; for equal quantities of both, when distilled, yielded precisely the same portion of alcohol †.

During the fermentation, a quantity of carbonic acid gas is constantly disengaged, not in a state of purity, but containing, combined with it, a portion of the wort; and if this gas be made to pass through water, it will deposite wort, which may be fermented in the usual manner *. Acetous Fermentation, Putrefaction.

When beer is distilled, alcohol is obtained, and the residuum is an acid liquor †. The theory of beer is so obviously the same with that of wine that it requires no additional explanation.

* *Collier, Manch. Mem.* v. 266

† *Ibid*, p. 260.

* *Collier, Manch. Mem.*

† *Ibid.*, *Manch. Mem.* ii. 257.

Sect. IV. *Of the Acetous Fermentation.*

187 Substances which undergo the acetous fermentation. If wine or beer be kept at a temperature between 70° and 90°, it gradually loses its properties, and is converted into *acetous acid*.

During this change, a quantity of oxygen gas is absorbed, and the whole of the spirituous part of the wine or beer disappears. Consequently its ingredients have mutually decomposed each other.

Neither pure alcohol, nor alcohol diluted with water, are capable of undergoing this change, neither do they absorb any oxygen. This absorption, then, is made by the mucilaginous matter which always exists in these liquids. No acetous acid is ever produced, unless some acid be present in the liquid. We may conclude, then, that the mucilage acquires the properties of an acid before it begins to act upon the spirituous part of the beer or the wine.

As the acetous acid has been already treated of in the article Chemistry, *Suppl.* it is unnecessary to dwell any longer on this subject here.

Sect. V. *Of Putrefaction.*

188 Nature of putrefaction. All vegetable substances, both complete plants and their component parts separately, when left entirely to themselves, are gradually decomposed and destroyed, provided moisture be present, and the temperature be not much under 45°, nor too high to evaporate suddenly all the moisture. This decomposition has obtained the name of *putrefaction*.

It proceeds with most rapidity in the open air; but the contact of air is not absolutely necessary. Water is, in all cases, essential to the process, and therefore is most probably decomposed.

Putrefaction is constantly attended with a fetid odour, owing to the emission of certain gaseous matters, which differ according to the putrefying substance. Some vegetable substances, as gluten, and cruciform plants, emit ammonia; others, as onions, seem to emit phosphorated hydrogen gas. Carbonic acid gas, and hydrogen gas, impregnated with unknown vegetable matters, are almost constantly emitted in abundance. When the whole process is finished, scarcely any thing remains but the earths, the salts, and the metals, which formed a constituent part of the vegetable. But our chemical knowledge of vegetable compounds is by far too limited to enable us to follow this very complicated process with any chance of success.

Part II. Of Animal SUBSTANCES.

Ingredients of Animals, Fibrina.

189 Classes of animals and vegetables

WHEN we compare animals and vegetables together, each in their most perfect state, nothing can be easier than to distinguish them. The plant is confined to a particular spot, and exhibits no marks of consciousness or intelligence; the animal, on the contrary, can remove at pleasure from one place to another, is possessed of consciousness, and a high degree of intelligence. But on approaching the contiguous extremities of the animal and vegetable kingdom, these striking differences gradually disappear, the objects acquire a greater degree of resemblance, and at last approach each other so nearly, that it is scarcely possible to decide whether some of those situated on the very boundary belong to the animal or vegetable kingdom.

Difficultly distinguished.

To draw a line of distinction, then, between animals and vegetables, would be a very difficult task; but it is not necessary for us, in this place at least, to attempt it; for almost the only animals whose bodies have been hitherto examined with any degree of chemical accuracy, belong to the most perfect classes, and consequently are in no danger of being confounded with plants. Indeed the greater number of facts which we have to relate, apply only to the human body, and to those of a few domestic animals. The task of analysing all animal bodies is immense, and must be the work of ages of indefatigable industry.

191 Division of this part.

We shall divide this part of the article into four chapters. In the first chapter, we shall give an account of the different ingredients hitherto found in animals, such of them at least as have been examined with any degree of accuracy: in the second, we shall treat of the different members of which animal bodies are composed; which must consist each of various combinations of the ingredients described in the first chapter: in the third, we shall treat of those animal functions which may be elucidated by chemistry: and, in the fourth, of the changes which animal bodies undergo after death.

Chap. I. Of the Ingredients of Animals.

The substances which have been hitherto detected in the animal kingdom, and of which the different parts of animals, as far as these parts have been analysed, are found to be composed, may be arranged under the following heads:

1. Fibrina,	8. Sulphur,
2. Albumen,	9. Oils,
3. Gelatine,	10. Acids,
4. Mucilage,	11. Alkalies,
5. Basis of bile,	12. Earths,
6. Urea,	13. Metals.
7. Sugar,	

These shall form the subject of the following sections:

Sect. I. *Of Fibrina.*

If a quantity of blood, newly drawn from an animal, be allowed to remain at rest for some time, a thick red clot gradually forms in it, and subsides. Separate this clot from the rest of the blood, wash it repeatedly in water till it ceases to give out any colour or taste to the liquid; the substance which remains after this process is denominated *fibrina*. It has been long known to physicians under the name of the *fibrous part of the blood*, but has not till lately been accurately described.

Albumen.

192 Fibrina how obtained.

193 Its properties.

Fibrina is of a white colour, has no taste, and is insoluble in water and in alcohol. It is soft and ductile, has a considerable degree of elasticity, and resembles very much the gluten of vegetables.

Pure fixed alkalies do not act upon it, unless they be very much concentrated, and then they decompose it. All the acids combine with it readily, and dissolve it. Water and alkalies separate it again; but it has lost entirely its former properties. With muriatic acid it forms a green coloured jelly.

When nitric acid is poured upon fibrina, azotic gas is disengaged, as Berthollet first discovered. The quantity of this gas is greater than can be obtained from the same quantity of other animal substances by the same process *. After this, prussic acid and carbonic acid gas are exhaled. By the assistance of heat the fibrina is dissolved; much nitrous gas is disengaged; the liquid, when concentrated, yields oxalic and malic acids, and white flakes are deposited, consisting of an oily substance, and of phosphat of lime †.

When fibrina is [illegible] a very large quantity of ammonia ‡.

These properties [illegible] to [illegible] that this substance is composed of [illegible] hydrogen, and carbon; but neither [illegible] nor the manner [illegible] known.

* Fourcroy, Ann. de Chim. i. 41.

† Fourcroy.

‡ Fourcroy, Ann. de Chim. i. 43.

Sect. II. Of Albumen.

194 Albumen contained in eggs.

The eggs of [illegible] contain two very different substances; a yellow [illegible] called the *yolk*; and a colourless glossy [illegible] liquid, distinguished by the name of *white*. This last is the substance which chemists have agreed to denominate *albumen* (1). The white of an egg, however, is not pure albumen. It contains, mixed with it, some carbonat of soda, and some sulphur; but the quantity of these substances is so small that they do not much influence its properties. We shall therefore consider it as *albumen*.

195 Coagulated by heat.

On the application of a heat of 165° § it *coagulates*, as is well known, into a white solid mass; the consistency of which, when other things are equal, depends, in some measure, on the time during which the heat was applied. The coagulated mass has precisely the same weight that it had while fluid.

§ Cullen.

The taste of coagulated albumen is quite different from that of liquid albumen: its appearance, too, and its

(1.) This is merely the Latin term for the white of an egg. It was first introduced into chemistry by the physiologists.

Albumen.

its properties, are entirely changed; for it is no longer soluble, as before, either in hot or in cold water.

196 Phenomena of this coagulation.

The coagulation of albumen takes place even though air be completely excluded; and even when air is present there is no absorption of it, nor does albumen in coagulating change its volume *. Acids have the property of coagulating albumen, as Scheele ascertained †. Alcohol also produces, in some measure, the same effect. *Heat*, then, *acids* and *alcohol*, are the agents which may be employed to coagulate albumen.

* *Carradori, Ann. de Chim.* xxix. 98.

† *Scheele*, ii. 58.

It is remarkable, that if albumen be diluted with a sufficient quantity of water, it can no longer be coagulated by any of these agents. Scheele mixed the white of an egg with ten times its weight of water, and then, though he even *boiled* the liquid, no coagulum appeared. Acids indeed, and alcohol, even then coagulated it; but they also lose their power, if the albumen be diluted with a much greater quantity of water, as has been ascertained by many experiments. Now we know, that when water is poured into albumen, not only a mechanical mixture takes place, but a chemical combination; for the albumen is equally distributed through every part of the liquid. Consequently its integrant particles must be farther separated from each other, and their distance must increase with the quantity of water with which they are diluted. We see, therefore, that albumen ceases to coagulate whenever its particles are separated from each other beyond a certain distance. That no other change is produced, appears evident from this circumstance, that whenever the watery solution of albumen is sufficiently concentrated by evaporation, coagulation takes place, upon the application of the proper agents, precisely as formerly.

It does not appear that the distance of the particles of albumen is changed by coagulation; for coagulated albumen occupies precisely the same sensible space as liquid albumen *.

* *Carradori.*

197 Enquiry into its cause.

Thus two things seem certain respecting the coagulation of albumen: 1. That its particles must not be beyond a certain distance; 2. That the coagulation does not produce any sensible change in their distance. To what, then, is the coagulation of albumen owing? We can conceive no change to take place from a state of liquidity to that of solidity, without some change in the figure of the particles of the body which has undergone that change: for if the figure and the distance of the particles of bodies continue the same, it is impossible to conceive any change at all to take place. Since, then, the distance of the particles of albumen does not, as far at least as we can perceive, change, we must conclude, that the figure of the particles actually does change. Now such a change may take place three ways: 1. The figure may be changed by the addition of some new molecules to each of the molecules of the body. 2. Some molecules may be abstracted from every integrant particle of the body. 3. Or the molecules, of which the integrant particles are composed, may enter into new combinations, and form new integrant particles, whose form is different from that of the old integrant particles. Some one or other of these three things must take place during the coagulation of albumen.

1. Scheele and Fourcroy have ascribed the coagulation of albumen to the first of these causes, namely, to the addition of a new substance. According to Scheele, *caloric* is the substance which is added. Fourcroy, on the contrary, affirms that it is *oxygen*.

Albumen.

Scheele supported his opinion with that wonderful ingenuity which shone so eminently in every thing which he did. He mixed together one part of white of egg and four parts of water, added a little pure alkali, and then dropt in as much muriatic acid as was sufficient to saturate the alkali. The albumen coagulated: but when he repeated the experiment, and used carbonat of alkali instead of pure alkali, no coagulation ensued. In the first case, says he, there was a double decomposition: the muriatic acid separated from a quantity of caloric with which it was combined, and united with the alkali; while, at the same instant, the caloric of the acid united with the albumen, and caused it to coagulate. The same combination could not take place when the alkaline carbonat was used, because the carbonic acid gas carried off the caloric, for which it has a strong affinity *.

*

This explanation is plausible; but it is contrary to every other known fact in chemistry, to suppose that caloric can combine with a substance without occasioning any alteration in its bulk, and cannot therefore be admitted without the most rigid proof.

Fourcroy observes, in support of his opinion, that the white of an egg is not at first capable of forming a hard coagulum, and that it only acquires that property by exposure to the atmosphere. It is well known that the white of a new laid egg is milky after boiling; and that if the shell be covered over with grease, to exclude the external air, it continues long in that state; whereas the white of an old egg, which has not been preserved in that manner, forms a very hard tough coagulum. These facts are undoubted; and they render it exceedingly probable, that albumen acquires the property of forming a hard coagulum only by absorbing oxygen: but they by no means prove that coagulation itself is owing to such an absorption. And since coagulation takes place without the presence of air, and since no air, even when it is present, is absorbed, this opinion cannot be maintained without inconsistency.

2. The only substance which can be supposed to leave albumen during coagulation, since it does not lose weight, is *caloric*. We know that in most cases where a fluid is converted into a solid, caloric is actually disengaged. It is extremely probable, then, that the same disengagement takes place here. But the opinion has not been confirmed by any proof. Fourcroy indeed says, that in an experiment made by him, the thermometer rose a great number of degrees. But as no other person has ever been able to observe any such thing, it cannot be doubted that this philosopher has been misled by some circumstance or other to which he did not attend †. It is usual, in many cases, for bodies to lose bulk when they give out caloric; but that there are exceptions to this rule, is well known.

† *Thomson's Fourc.* iii. 27

3. Even if the second opinion were true, it is scarcely possible to conceive the coagulation of albumen to take place without some change in its integrant particles. We can see how all the substances which coagulate albumen might produce such a change; and the insolubility of coagulated albumen in water, and its other different properties, render it more than probable that some such change actually takes place. But what that change is, cannot even be conjectured.

The

Gelat. The coagulation of albumen is intimately connected with one of the moſt important problems in chemiſtry, namely, the cauſe of fluidity and ſolidity. But this problem can only be reſolved, with any proſpect of ſucceſs, by a geometrical inveſtigation of the phenomena of heat.

Properties of albumen

Coagulated albumen is diſſolved by the mineral acids, greatly diluted with water; and if a concentrated acid be added to the ſolution, the albumen is again precipitated *. Alkalies, however, do not precipitate it from its ſolution in acids †. But if a ſolution of tan be poured into the acid ſolution of albumen, a very copious precipitate appears ‡.

* Scheele, ii. 57.
† Vauquelin, Ann. de Chim. xxix. 15.
‡ Ibid.

If the ſolution of tan be poured into an aqueous ſolution of uncoagulated albumen, it forms with it a very copious precipitate, which is inſoluble in water. This precipitate is a combination of tan and albumen. This property which albumen has of precipitating with tan, was diſcovered by Seguin §: it furniſhes us with a method of detecting the preſence of albumen in any liquid in which we ſuſpect it.

§ Nicholſon's Journal, i. 271

Pure alkalies and lime water alſo diſſolve albumen; at the ſame time ammonia is diſengaged, owing to the decompoſition of part of the albumen. Acids precipitate the albumen from alkalies, but its properties are changed *.

* Scheele, ii. 57.

Nitric acid, when aſſiſted by heat, diſengages azotic gas from albumen †; but the quantity is not ſo great as may be obtained from fibrina ‡. The albumen is gradually diſſolved, nitrous gas is emitted, oxalic and malic acids are formed, and a thick oily matter makes its appearance on the ſurface §. When diſtilled, it furniſhes the ſame products as fibrina, only the quantity of ammonia is not ſo great ‖.

† Scheele and Berthollet.
‡ Fourcroy, Ann. de Chim. i. 41
§ Scheele, Crell's Annals, ii. 17. Eng. Tranſl.
‖ Fourcroy, Ann. de Chim. i. 43.

Hence it follows, that albumen is compoſed of azot, hydrogen, and carbon, as well as fibrina; but the proportion of azot is not ſo great in the firſt ſubſtance as in the ſecond.

SECT. III. *Of GELATINE.*

109 Gelatine how obtained.

IF a piece of the freſh ſkin of an animal, an ox for inſtance, after the hair and every impurity is carefully ſeparated, be waſhed repeatedly in cold water, till the liquid ceaſes to be coloured, or to abſtract any thing; if the ſkin, thus purified, be put into a quantity of pure water, and boiled for ſome time, part of it will be diſſolved. Let the decoction be ſlowly evaporated till it is reduced to a ſmall quantity, and then put aſide to cool. When cold, it will be found to have aſſumed a ſolid form, and to reſemble preciſely that tremulous ſubſtance well known to every body under the name of *gelly*. This is the ſubſtance called in chemiſtry *gelatine*. If the evaporation be ſtill farther continued, by expoſing the gelly to dry air, it becomes hard, ſemitranſparent, breaks with a gloſſy fracture, and is in ſhort the ſubſtance ſo much employed in different arts under the name of *glue*. Gelatine, then, is preciſely the ſame with glue; only that it muſt be ſuppoſed always free from thoſe impurities with which glue is ſo often contaminated.

110 Its properties.

Gelatine is tranſparent and colourleſs; when thrown into water, it very ſoon ſwells, and aſſumes a gelatinous form, and gradually diſſolves completely. By evaporating the water, it may be obtained again unaltered in the form of gelly.

Animal Mucilage.

When an infuſion of tan is dropt into a ſolution of gelatine in water, there is inſtantly formed a copious white precipitate, which has all the properties of leather. This precipitate is compoſed of tan and gelatine. Theſe two ſubſtances, therefore, when combined, form leather. Albumen and gelatine are the only animal ſubſtances known which have the property of combining with tan, and forming with it an inſoluble compound. They may be always eaſily detected, therefore, by means of tan; and they may be readily diſtinguiſhed from each other, as albumen alone coagulates by heat, and gelatine alone concretes into a gelly.

Gelatine is inſoluble in alcohol, and is even precipitated from water by it; but both acids and alkalies diſſolve it. Nitric acid diſengages from it a ſmall quantity of azotic gas; diſſolves it, when aſſiſted by heat, excepting an oily matter, which appears on the ſurface of the ſolution; and converts it, partly into oxalic and malic acids *.

* Scheele, Crell's Ann. ii. 17. Eng. Tranſl.

When diſtilled, there comes over firſt water, containing ſome animal matter; the gelatine then ſwells, becomes black, emits a fetid odour, accompanied with acrid fumes: Some empyreumatic oil then comes over, and a very ſmall quantity of carbonat of ammonia: its coaly reſiduum remains behind. Theſe phenomena ſhew, that gelatine is compoſed of carbon, hydrogen, and azot; but the proportion of azot is evidently much ſmaller than in either fibrina or albumen †.

† Fourcroy, Ann. de Chim. i. 41.

SECT. IV. *Of ANIMAL MUCILAGE.*

No word in chemiſtry is uſed with leſs accuracy than *mucilage*. It ſerves as a common name for almoſt every animal ſubſtance which cannot be referred to any other claſs.

None of the ſubſtances on which the name of *animal mucilage* has been given, have been examined with care; of courſe it is unknown whether theſe ſubſtances be the ſame or different.

201 Properties of mucilage.

Whenever an animal ſubſtance poſſeſſes the following properties, it is at preſent denominated an animal mucilage by chemiſts.

1. Soluble in water.
2. Inſoluble in alcohol.
3. Neither coagulating by heat, nor concreting into a gelly by evaporation.
4. Not precipitated by the ſolution of tan.

Moſt of the ſubſtances called *mucilage* have alſo the property of abſorbing oxygen, and of becoming by that means inſoluble in water.

The mucilaginous ſubſtances ſhall be pointed out in the next chapter. In the preſent ſtate of our knowledge, any account of them here would merely be a repetition of the properties juſt mentioned.

SECT. V. *Of the BASIS of BILE.*

202 Baſis of bile how obtained.

INTO 32 parts of freſh ox bile pour one part of concentrated muriatic acid. After the mixture has ſtood for ſome hours, paſs it through a filter, in order to ſeparate a white coagulated ſubſtance. Pour the filtrated liquor, which has a fine green colour, into a glaſs veſſel, and evaporate it by a moderate heat. When it has arrived at a certain degree of concentration, a green coloured ſubſtance precipitates. Decant off the clear liquid, and waſh the precipitate in a ſmall quantity of pure

Basis of Bile.

pure water. This precipitate is the *basis of bile*, or the *resin of bile*, as it is sometimes called *.

203 Its properties

The basis of bile is of a black colour; but when spread out upon paper or on wood, it is green: its taste is intensely bitter †.

When heated to about 122°, it melts; and if the heat be still farther increased, it takes fire, and burns with rapidity. It is soluble in water, both cold and hot, and still more soluble in alcohol; but water precipitates it from that liquid ‡.

It is soluble also in alkalies, and forms with them a compound which has been compared to a soap. Acids, when sufficiently diluted, precipitate it both from water and alkalies without any change; but if they be concentrated, the precipitate is redissolved §.

When distilled, it furnishes some sebacic acid ‖.

204 Combines with oxygen.

From these properties, it is clear that the basis of bile has a considerable resemblance to oils; but it differs from them entirely in several of its properties. The addition of oxygen, with which it combines readily, alters it somewhat, and brings it still nearer to the class of oils.

In this altered state, the basis of bile may be obtained by the following process. Pour oxy-muriatic acid cautiously into bile till that liquid loses its green colour; then pass it through a filter to separate some albumen which coagulates. Pour more oxy-muriatic acid into the filtered liquid, and allow the mixture to repose for some time. The oxy-muriatic acid is gradually converted into common muriatic acid; and in the mean time the basis of bile absorbs oxygen, and acquires new properties. Pour into the liquid, after it has remained a sufficient time, a little common muriatic acid, a white precipitate immediately appears, which may be separated from the fluid. This precipitate is the basis of bile combined with oxygen.

It has the colour and the consistence of tallow, but still retains its bitter taste. It melts at the temperature of [illegible]. It dissolves readily in alcohol, and even in water, provided it be assisted by heat. Acids precipitate it from these solutions ¶.

SECT. VI. Of Urea.

205 Urea how obtained.

EVAPORATE, by a gentle heat, a quantity of human urine voided six or eight hours after a meal, till it be reduced to the consistence of a thick syrup. In this state, when put by to cool, it concretes into a crystalline mass. Pour, at different times, upon this mass four times its weight of alcohol, and apply a gentle heat; a great part of the mass will be dissolved, and there will remain only a number of saline substances. Pour the alcohol solution into a retort, and distil by the heat of a sand bath till the liquid, after boiling some time, is reduced to the consistence of a thick syrup. The whole of the alcohol is now separated, and what remains in the retort crystallizes as it cools. These crystals consist of the substance known by the name of *urea* *.

This substance was first described by Rouelle the Younger in 1773, under the name of the *saponaceous extract of urine*. He mentioned several of its properties; but very little was known concerning its nature till Fourcroy and Vauquelin published their experiments on it in 1799. These celebrated chemists have given it the name of *urea*, which we have adopted.

206 Its properties

Urea, obtained in this manner, has the form of crystalline plates crossing each other in different directions. Its colour is yellowish white; it has a fetid smell, somewhat resembling that of garlic or arsenic; its taste is strong and acrid, resembling that of ammoniacal salts; it is very viscid and difficult to cut, and has a good deal of resemblance to thick honey †. When exposed to the open air, it very soon attracts moisture, and is converted into a thick brown liquid. It is extremely soluble in water; and during its solution, a considerable degree of cold is produced ‡. Alcohol dissolves it with facility, but scarcely in so large a proportion as water. The alcohol solution yields crystals much more readily on evaporation than the solution in water.

When nitric acid is dropt into a concentrated solution of urea in water, a great number of bright pearl coloured crystals are deposited, composed of urea and nitric acid. No other acid produces this singular effect. The concentrated solution of urea in water is brown, but it becomes yellow when diluted with a large quantity of water. The infusion of nut galls gives it a yellowish brown colour, but causes no precipitate. Neither does the infusion of tan produce any precipitate ‖.

When heat is applied to urea, it very soon melts, swells up, and evaporates, with an insupportably fetid odour. When distilled, there comes over first benzoic acid, then carbonat of ammonia in crystals, some carbonated hydrogen gas, with traces of prussic acid and oil; and there remains behind a large residuum, composed of charcoal, muriat of ammonia, and muriat of soda. The distillation is accompanied with an almost insupportably fetid alliaceous odour. Two hundred and eighty-eight parts of urea yield by distillation 200 parts of carbonat of ammonia, 10 parts of carbonated hydrogen gas, 7 parts of charcoal, and 68 parts of benzoic acid, muriat of soda, and muriat of ammonia. These three last ingredients Fourcroy and Vauquelin consider as foreign substances, separated from the urine by the alcohol at the same time with the urea. Hence it follows, that 100 parts of urea, when distilled, yield 207 Its component parts.

92.027	carbonat of ammonia,
4.608	carbonated hydrogen gas,
3.225	charcoal.
99.860	

Now 200 parts of carbonat of ammonia are composed of 86 ammonia, 90 carbonic acid gas, and 24 water. Hence it follows, that 100 parts of urea are composed of

39.5	oxygen,
32.5	azot,
14.7	carbon,
13.3	hydrogen.
100.0	

But it can scarcely be doubted, that the water which was found in the carbonat of ammonia existed ready formed in the urea before the distillation ¶.

When the solution of urea in water is kept in a boiling heat, and new water is added as it evaporates, the urea is gradually decomposed, a very great quantity of carbonat of ammonia is disengaged, and at the same time acetous acid is formed, and some charcoal precipitates *.

208 Spontaneous decomposition.

When a solution of urea in water is left to itself for some time, it is gradually decomposed. A froth col-

 lects

Urea. lects on its surface; air bubbles are emitted which have a strong disagreeable smell, in which ammonia and acetous acid are distinguishable. The liquid contains a quantity of acetous acid. The decomposition is much more rapid if a little gelatine be added to the solution. In that case more ammonia is disengaged, and the proportion of acetous acid is not so great*.

209 Action of acids. When the solution of urea is mixed with one fourth of its weight of diluted sulphuric acid, no effervescence takes place; but, on the application of heat, a quantity of oil appears on the surface, which concretes upon cooling; the liquid, which comes over into the receiver, contains acetous acid, and a quantity of sulphat of ammonia remained in the retort dissolved in the undistilled mass. By repeated distillations, the whole of the urea is converted into acetous acid and ammonia †.

When nitric acid is poured upon crystallized urea, a violent effervescence takes place, the mixture frothes, assumes the form of a dark red liquid, great quantities of nitrous gas, azotic gas, and carbonic acid gas, are disengaged. When the effervescence is over, there remains only a concrete white matter, with some drops of reddish liquid. When heat is applied to this residuum, it detonates like nitrat of ammonia. Into a solution of urea, formed by its attracting moisture from the atmosphere, an equal quantity of nitric acid, of the specific gravity 1.460, diluted with twice its weight of water, was added; a gentle effervescence ensued: very gentle heat was applied, which supported the effervescence for two days. There was disengaged the first day a great quantity of azotic gas and carbonic acid gas; the second day, carbonic acid gas, and at last nitrous gas. At the same time with the nitrous gas an odour was perceivable of the oxygenated prussic acid of Berthollet. At the end of the second day, the matter in the retort, which was become thick, took fire, and burnt with a violent explosion. The residuum contained traces of prussic acid and ammonia. The receiver contained a yellowish acid liquor, on the surface of which some drops of oil swam ‡.

Muriatic acid dissolves urea, but does not alter it. Oxy-muriatic acid gas is absorbed very rapidly by a diluted solution of urea; small whitish flakes appear, which soon become brown, and adhere to the sides of the vessel like a concrete oil. After a considerable quantity of oxy-muriatic acid had been absorbed, the solution, left to itself, continued to effervesce exceeding slowly, and to emit carbonic acid and azotic gas. After this effervescence was over, the liquid contained muriat and carbonat of ammonia.

210 Of alkalies. Urea is dissolved very rapidly by a solution of potass or soda; and at the same time a quantity of ammonia is disengaged. the same substance is disengaged when urea is treated with barytes, lime, or even magnesia. Hence it is evident, that this appearance must be ascribed to the muriat of ammonia, with which it is constantly mixed. When pure solid potass is triturated with urea, heat is produced, a great quantity of ammonia is disengaged. The mixture becomes brown, and a substance is deposited, having the appearance of an empyreumatic oil. One part of urea and two of potass, dissolved in four times its weight of water, when distilled give out a great quantity of ammoniacal water; the residuum contained acetite and carbonat of potass ||.

When muriat of soda is dissolved in a solution of urea in water, it is obtained by evaporation, not in cubic crystals, its usual form, but in regular octohedrons. Muriat of ammonia, on the contrary, which crystallizes naturally in octohedrons, is converted into cubes, by dissolving and crystallizing it in the solution of urea.

Such are the properties of this singular substance, as far as they have been ascertained by the experiments of Fourcroy and Vauquelin. It differs from all animal substances hitherto examined, in the great proportion of azot which enters into its composition, and in the facility with which it is decomposed, even by the heat of boiling water.

SECT. VII. *Of Sugar.*

Sugar has been already described in the former part of this article as a vegetable substance; nothing therefore is necessary here but to point out the different states in which it is found in animals. It has never indeed been found in animals in every respect similar to the sugar of vegetables; but there are certain animal substances which have so many properties in common with sugar, that they can scarcely be arranged under any other name. These substances are,

1. Sugar of milk,
2. Honey,
3. Sugar of diabetic urine.

1. The method of obtaining sugar of milk has been already detailed in the article Chemistry, n° 488. to which we refer the reader. For an account of its properties, we are indebted to the observations of Mr Lichtenstein. 211 Sugar of milk.

When pure, it has a [illegible] taste, and no smell. Its crystals are [illegible] regular parallelopipeds [illegible] pyramids. Its specific gravity [illegible] At that temperature [illegible] its weight of water [illegible] in alcohol. When burnt, it [illegible] and exhibits precisely [illegible]. When distilled, it yields [illegible] the empyreumatic oil [illegible] acid §.

2. Honey [illegible] belongs to the [illegible] kingdom. It has a white or [illegible] consistence, a [illegible] smell; by means of alcohol, and even by water, with peculiar management, a true sugar is obtained; by distillation it affords an acid phlegm and an oil, and its coal is light and spongy like that of the mucilages of plants. Nitric acid extracts the oxalic acid, which is entirely similar to that of sugar; it is very soluble in water, with which it forms a syrup, and like sugar passes to the vinous fermentation *. 212 Honey.

3. The urine of persons labouring under the disease known to physicians by the name of *diabetes*, yields, when evaporated, a considerable quantity of matter, which possesses the properties of sugar.

SECT. VIII. *Of Oils.*

The oily substances found in animals may be arranged under three heads: 1. Fixed oils; 2. Fat; 3. Spermaceti. 213 Fixed oils.

1. The fixed oils are obtained chiefly from different kinds of fish, as the whale, &c.; and they are distinguished

* Fourcroy and Vauquelin, Ann. de Chim. xxxii. p. 96.

† Ibid. p. 104.

‡ Ibid. p. 107.

|| Ibid.

§ Scheele, ii. 70.

* Fourcroy.

Oils. guished by the name of the animal from which they are obtained, as *whale oil*, &c. These oils agree in their properties with other fixed oils; which have been already described in the article CHEMISTRY, Part II. Chap. iii. *Suppl.*

214 Properties of fat.

2. *Fat*, or rather tallow, is a well-known animal substance, much employed in the manufacture of candles and soap.

It has a white colour, often with a shade of yellow. When fresh, it has no smell, and but little taste. While cold, it is hard and brittle; but when exposed to the heat of 92°, it melts, and assumes the appearance of oil. The fat, however, which is extracted from flesh by boiling, does not melt till it reach the temperature of 127°*. Tallow and fat, in other respects, have the properties of fixed oils. They seem to be composed of a fixed oil combined with sebacic acid. When strongly heated, with contact of air, it emits a smoke of a penetrating smell, which excites tears and coughing, and takes fire when sufficiently heated to be volatilized: the charcoal it affords is not abundant. If fat be distilled on a water-bath, an insipid water, of a slight animal smell, is obtained, which is neither acid nor alkaline, but which soon acquires a putrid smell, and deposites filaments of a mucilaginous nature. This phenomenon, which takes place with the water obtained by distillation on the water-bath from any animal substance, proves, that this fluid carries up with it a mucilaginous principle, which is the cause of its alteration. Fat, distilled in a retort, affords phlegm, at first aqueous, and afterwards strongly acid; an oil, partly liquid, and partly concrete; and a very small quantity of charcoal, exceedingly difficult to incinerate; in which Crell found a small quantity of [illegible] of lime. These products have an acid and penetrating smell, as strong as that of sulphurous acid. The acid is the sebacic.

* Nicholson's Journal, i. 71.

215 Properties of spermaceti.

3. *Spermaceti* [illegible] crystalline, semitransparent [illegible] which is taken out [illegible] the cachalot; it is [illegible] of another [illegible] with which it is mixed. This [illegible] chemical properties; [illegible] some respects, and volatile oils in others.

[illegible] heated to the temperature of 133°†, it melts; and if the heat be increased, it evaporates without much alteration. When repeatedly distilled, however, it loses its solid form, and becomes like oil. When heated in contact with air, it takes fire, and burns uniformly without any disagreeable odour: hence its use in making candles.

† Ibid.

By long exposure in hot air it becomes yellow and rancid. Pure alkali combines with it, and forms a soap. Nitric and muriatic acids do not affect it, but sulphuric acid dissolves it and alters its colour.

SECT. IX. *Of Acids.*

Acids. THE acids hitherto discovered in the animal kingdom are the nine following.

1. Sulphuric,	4. Carbonic,	7. Formic,
2. Muriatic,	5. Benzoic,	8. Bombyc,
3. Phosphoric,	6. Sebacic,	9. Uric.

The first eight of these have been already described in the article CHEMISTRY, *Suppl.* it is unnecessary therefore to describe them here.

216 Discovery of uric acid.

Few persons are ignorant that concretions sometimes form in the human urinary bladder, and produce that very formidable disease known by the names of the *stone* and the *gravel*. These concretions are often extracted by a surgical operation: they are called *urinary calculi*.

The most common of these calculi is of a brown colour, and very soluble in pure potass or soda ley.

If into an alkaline solution of one of these calculi a quantity of acetous acid be poured, a copious brown coloured precipitate immediately appears, which may be separated and edulcorated in a small quantity of water. This substance is *uric acid* *.

* F[illegible] 3.

It was discovered by Scheele in 1776, and the French chemists afterwards called it *lithic acid*: but this name, in consequence chiefly of some remarks of Dr Pearson on its impropriety, has been lately given up, and that of *uric* (L) acid substituted in its place. We have adopted the new name, because we think it preferable to the old; which indeed conveyed a kind of inconsistency to those who attended to the etymological meaning of the word.

217 Its properties.

Uric acid possesses the following properties: it crystallizes in thin plates; has a brown colour, and scarcely any taste. Cold water scarcely dissolves any part of it; but it is soluble in 360 parts of boiling water. The solution reddens vegetable blues, especially the tincture of turnsol. A great part of the acid precipitates again as the water cools. It combines readily with alkalies and earths; but the compound is decomposed by every other acid. Sulphuric acid, when concentrated, decomposes it entirely *. Nitric acid dissolves it readily: the solution is of a pink colour, and has the property of tinging animal substances, the skin for instance, of the same colour †. When this solution is boiled, a quantity of azotic gas, carbonic acid gas, and of prussic acid, is disengaged ‡. Oxy-muriatic acid converts it in a few minutes into oxalic acid §.

When distilled, about a fourth of the acid passes over a little altered, and is found in the receiver crystallized in plates; a few drops of thick oil make their appearance; $\frac{1}{4}$th of the acid of concrete carbonat of ammonia, some prussiat of ammonia, some water, and carbonic acid; and there remains in the retort charcoal, amounting to about $\frac{1}{10}$th of the weight of the acid distilled ‖.

These facts are sufficient to shew us, that uric acid is composed of carbon, azot, hydrogen, and oxygen; and that the proportion of the two last ingredients is much smaller than of the other two.

The different salts which uric acid forms with alkaline and earthy bases have not been examined with attention; but urat of potass, of soda, and of lime, have been formed both by Scheele and Fourcroy; and urat of

* Scheele, i 203.

† Ibid. and Pearson.

§ Brugnatelli, ibid. xxxii. 184.

‖ Fourcroy, ibid xvi.

(L) From *urine*; because this acid is always found in human urine.

Alkalie, Earths, and Metals.

of ammonia is not unfrequently found cryſtallized in urinary calculi.

The order of the affinities of the different baſes for uric acids is entirely unknown; but it has been aſcertained, that its affinity for theſe baſes is much weaker than that of any other acid. Its ſalts are decompoſed even by pruſſic and carbonic acid.

Sect. X. *Of Alkalies, Earths, and Metals.*

1. All the three alkalies have been found in the animal kingdom, as we ſhall ſhew in the next chapter.

2. The only earths which have been found in animals are,

1. Lime,
2. Magneſia,
3. Silica.

The firſt in great abundance, almoſt in every large animal; the other two very rarely, and only as it were by accident.

3. The metals hitherto found in animals are,

1. Iron,
2. Manganeſe.

The firſt exiſts in all the larger animals in ſome conſiderable quantity; the ſecond has ſcarce ever been found in any quantity ſo great as to admit of being weighed.

218 Subſtances found in animals.

Such are the ſubſtances hitherto found in animals. The ſimple bodies of which all of them conſiſt are the following:

1. Azot,	6. Phoſphorus,	11. Magneſia,
2. Carbon,	7. Muriatic acid,	12. Silica,
3. Hydrogen,	8. Potaſs,	13. Iron,
4. Oxygen,	9. Soda,	14. Manganeſe.
5. Lime,	10. Sulphur,	

Of theſe, magneſia and ſilica may in a great meaſure be conſidered as foreign bodies; for they are only found in exceedingly minute quantities, and the laſt not unleſs in caſes of diſeaſe. The principal elementary ingredients are the firſt ſix: animal ſubſtances may be conſidered as in a great meaſure compoſed of them. The firſt four conſtitute almoſt entirely the ſoft parts, and the other two form the baſis of the hard parts. But we will be able to judge of this much better, after we have taken a view of the various parts of animals as they exiſt ready formed in the body. This ſhall be the ſubject of the next chapter.

Chap. II. Of the Parts of Animals.

The different ſubſtances which compoſe the bodies of animals have been deſcribed with ſufficient minuteneſs in the article Anatomy, *Encycl.* to which we beg leave to refer the reader. Any repetition in this place would be improper. Theſe ſubſtances are the following:

1. Bones and ſhells,	6. Cartilages,
2. Muſcles,	7. Skin,
3. Tendons,	8. Brain and nerves,
4. Ligaments,	9. Horns and nails,
5. Membranes,	10. Hair and feathers.

Beſides theſe ſubſtances which conſtitute the ſolid part of the bodies of animals, there are a number of fluids, the moſt important of which is the *blood*, which pervades every part of the ſyſtem in all the larger animals: The reſt are known by the name of *ſecretions*, becauſe they are formed or *ſecreted*, as the anatomiſts term it, from the blood. The principal animal ſecretions are the following:

Bones.

1. Milk,	6. Mucus of the noſe,
2. Saliva,	7. Synovia,
3. Pancreatic juice,	8. Semen,
4. Bile and biliary calculi,	9. Liquor of the amnios,
5. Tears,	10. Urine and urinary calculi.

Theſe ſubſtances ſhall form the ſubject of the following ſections.

Sect. I. *Of Bones.*

By *bones*, we mean thoſe hard, ſolid, well known ſubſtances, to which the firmneſs, ſhape, and ſtrength of animal bodies, are owing; which, in the larger animals, form, as it were, the ground-work upon which all the reſt is built. In man, in quadrupeds, and many other animals, the bones are ſituated below the other parts, and ſcarcely any of them are expoſed to view; but ſhell-fiſh and ſnails have a hard covering on the outſide of their bodies, evidently intended for defence. As theſe coverings, though known by the name of *ſhells*, are undoubtedly of a bony nature, we ſhall include them alſo in this ſection. For the very ſame reaſons, it would be improper to exclude *egg-ſhells*, and thoſe coverings of certain animals, the tortoiſe for inſtance, known by the name of *cruſts*.

It had been long known, that bones may be rendered ſoft and cartilaginous by keeping them in diluted acid ſolutions, and that ſome acids even diſſolve them altogether; that when expoſed to a violent heat, they become white, opaque, and brittle; and Dr Lewis had obſerved, that a ſudden and violent heat rendered them hard, ſemitranſparent, and ſonorous. But their component parts remained unknown till Scheele mentioned, in his diſſertation on Fluor Spar publiſhed in the Stockholm Tranſactions for 1771, that the earthy part of bones is *phoſphat of lime* (M). Since that time conſiderable additions have been made to the chemical analyſis of theſe ſubſtances by Bernard, Bouillon, and Rouelle. Mr Hatchett has publiſhed a very valuable paper on the ſubject in the Philoſophical Tranſactions for 1799; and in the 34th volume of the *Annales de Chimie*, Mr Merat-Guillot has given us a table of the component parts of the bones of a conſiderable number of animals.

The *bony parts* of animals may be divided into three claſſes; namely, *bones*, *cruſts*, and *ſhells*.

1. Bones have a conſiderable degree of hardneſs; when recent, they contain a quantity of marrow, which may be partly ſeparated from them. When the water in which bones have been for ſome time boiled is evaporated to a proper conſiſtence, it aſſumes the form of a *gelly*; bones therefore contain *gelatine*. 219 Properties of bones.

If a piece of bone be kept for ſome time in diluted muriatic, or even acetous acid, it gradually loſes a conſiderable part of its weight, becomes ſoft, and acquires 220 Their component parts.

(M) The diſcoverer of this has not been completely aſcertained: Scheele does not claim it in that paper; Bergman gives it to Gahn; but Crell affirms that it was made by Scheele.

Bones.

a certain degree of tranſparency; and, in ſhort, acquires all the properties of *cartilage*. Bone therefore conſiſts of *cartilage*, combined with ſome ſubſtance which theſe acids are capable of diſſolving and carrying off.

If pure ammonia be dropt into the acid which has reduced the bone to this ſtate, a quantity of white powder precipitates, which poſſeſſes all the properties of *phoſphat of lime*. The ſubſtance, then, which was combined with the cartilage is *phoſphat of lime*.

After the phoſphat of lime has precipitated, the addition of carbonat of ammonia occaſions a farther precipitate, which conſiſts of carbonat of lime: but the quantity of this precipitate is inconſiderable *. When concentrated acids are poured on bones, whether recent or calcined, an efferveſcence is perceptible; the gas which eſcapes renders lime water turbid, and is therefore *carbonic acid*. Now ſince bones contain carbonic acid, and ſince they contain lime alſo uncombined with any acid ſtronger than carbonic—it is evident that they contain a little *carbonat of lime*. Mr Hatchett found this ſubſtance in all the bones of quadrupeds and of fiſh which he examined †.

When bones are calcined, and the reſiduum is diſſolved in nitric acid, nitrat of barytes cauſes a ſmall precipitate, which is inſoluble in muriatic acid, and is therefore ſulphat of barytes ‡. Conſequently bones contain ſulphuric acid. It has been aſcertained, that this acid is combined with lime. The proportion of *ſulphat of lime* in bones is very inconſiderable.

Thus we have ſeen, that bones are compoſed of cartilage, which conſiſts almoſt entirely of gelatine, of phoſphat of lime, carbonat of lime, and ſulphat of lime. The following table, drawn up by Merat-Guillot ‖, exhibits a comparative view of the relative proportion of theſe ingredients in a variety of bones. The ſulphat of lime, which occurs only in a very ſmall quantity, has been confounded with phoſphat of lime.

One hundred parts contain	Gelatine.	Phoſph. of lime	Carb. of lime	Loſs.
Human bones from a burying ground,	16	67	1.5	15.5
Do. dry, but not from under the earth,	23	63	2	2
Bone of ox,	3	93	2	2
calf,	25	54	trace	21
horſe,	9	67.5	1.25	22.25
ſheep,	16	70	0.5	13.5
elk,	1.5	90	1	7.5
hog,	17	52	1	30
hare,	9	85	1	5
pullet,	6	72	1.5	20.5
pike,	12	64	1	23
carp,	6	45	0.5	48.5

Ivory,	24	64	0.1	11.15
Hartſhorn,	27	57.5	1	14.5

The enamel of the teeth is compoſed of the ſame earthy ingredients as other bones; but it is totally deſtitute of cartilage *.

221 Component parts of cruſts.

2. The cruſtaceous coverings of animals, as of echini, crabs, lobſters, prawns, and cray-fiſh, and alſo the ſhells of eggs, are compoſed of the ſame ingredients as bones; but in them the proportion of carbonat of lime far exceeds that of phoſphat *.

Thus 100 parts of lobſter cruſt contain
60 carbonat of lime,
14 phoſphat,
26 cartilage,

100 †.

One hundred parts of crawfiſh cruſt contain
60 carbonat of lime,
12 phoſphat of lime,
28 cartilage.

100 ‡.

One hundred parts of hens egg-ſhells contain
89.6 carbonat of lime,
5.7 phoſphat of lime,
4.7 animal matter.

100.0 ‖.

Mr Hatchett found traces of phoſphat of lime alſo in the ſhells of ſnails.

222 Component parts of ſhells.

3. The ſhells of ſea animals may be divided into two claſſes: The firſt has the appearance of porcelain; their ſurface is enamelled, and their texture is often ſlightly fibrous. Mr Hatchett, has given them the name of *porcellaneous* ſhells. The ſecond kind of ſhell is known by the name of *mother of pearl*. It is covered with a ſtrong epidermis, and below it lies the ſhelly matter in layers *. The ſhell of the freſh water muſcle, mother of pearl, heliotis iris, and turbo olearius, are inſtances of theſe ſhells.

Porcellaneous ſhells are compoſed of carbonat of lime cemented together by a very ſmall quantity of animal matter †.

Mother of pearl ſhells are compoſed of alternate layers of carbonat of lime and a thin membranaceous or cartilaginous ſubſtance. This cartilage ſtill retains the figure of the ſhell, after all the carbonat of lime has been ſeparated by acids ‡.

Mother of pearl contains 66 carbonat of lime,
34 cartilage.

100 ‖.

Coral, which is a bony ſubſtance formed by certain ſea inſects, has a nearer relation to mother of pearl ſhells in its ſtructure than to any other bony ſubſtance, as the following table ¶ will ſhew.

	White coral.	Red coral.	Articulated coralline.
Carbonat of lime,	50	53.5	49
Animal matter,	50	46.5	51
	100	100.0	

SECT. II. *Of the* MUSCLES *of* ANIMALS.

THE muſcular parts of animals are known in common language by the name of *fleſh*. They conſtitute a conſiderable proportion of the food of man.

Muſcular fleſh is compoſed of a great number of fibres or threads, commonly of a reddiſh or whitiſh colour; but its appearance is too well known to require any deſcription. Hitherto it has not been ſubjected to any accurate chemical analyſis. Mr Thouvenel, indeed, has publiſhed a very valuable diſſertation on the ſubject;

Notes (left margin): * Hatchett, Phil. Tranſ. 1799, p. 327. † Ibid. ‡ Ibid. ‖ Ann. de Chim. xxxiv. 71. * Hatchett, Phil. Tranſ. 1799, p. 328.

Muscles of Animals.

subject; but his analysis was made before the method of examining animal substances was so well understood as it is at present. It is to him, however, that we are indebted for almost all the facts known concerning the composition of muscle.

It is scarcely possible to separate the muscle from all the other substances with which it is mixed. A quantity of fat often adheres to it closely; blood pervades the whole of it; and every fibre is enveloped in a particular thin membranous matter, which anatomists distinguish by the name of *cellular substance*. The analysis of the muscle, then, cannot be supposed to exhibit an accurate view of the composition of pure muscular fibres, but only of muscular fibre not perfectly separated from other substances.

223 Analysis of muscles.

1. When a muscle is well washed in cold water, several of its parts are dissolved, and may be obtained by the usual chemical methods. When the water is evaporated slowly, it at last coagulates, and the coagulum may be separated by means of a filter. It possesses the properties of *albumen*.

2. The water is then to be evaporated gently to dryness, and alcohol poured upon the dry mass: part of it is dissolved by digestion, and there remains a saline substance, which has not been examined; but which Fourcroy conjectures to be a *phosphat*.

3. When the alcohol is evaporated to dryness, it leaves a peculiar mucous substance, soluble both in water and alcohol; and when its watery solution is very much concentrated, it assumes an acid and bitter taste. It swells upon hot coals, and melts, emitting an acid and penetrating smell. It attracts moisture from the air, and forms a saline efflorescence. In a hot atmosphere it becomes sour and putrefies. All these properties render it probable that this substance of Mr Thouvenel is that which is converted into *zoonic* acid during the roasting of meat.

4. The muscle is now to be boiled in water for some time. A quantity of fat appears on its surface in the form of oil, which may be taken off.

5. The water, when evaporated sufficiently, assumes the form of a jelly on cooling, and therefore contains a portion of *gelatine*. It contains also a little of the saline substance, and of the mucous substance mentioned above.

6. The residuum of the muscle is now white and insipid, of a fibrous structure, and insoluble in water, and has all the properties of *fibrina*.

Thus it appears that muscle is composed of

Albumen,
Mucous matter,
Gelatine,
Fibrina,
A salt.

The French chemists have discovered, that when a piece of muscle is allowed to remain a sufficient time in diluted sulphuric acid, it is converted into a substance resembling tallow: weak nitric acid, on the other hand, converts it into a substance resembling *wax* *.

* Humboldt on Galvanism, 170.

Sect. III. *Of the Soft and White Parts of Animals.*

Those parts of animals to which anatomists have given the names of cartilage, tendon, ligament, membrane, differ altogether in their appearance from the muscles. They have never been analysed. We know only that they are composed, in a great measure, of *gelatine*; for it is partly from them that *glue* is made; which does not differ from gelatine, except in not being perfectly pure.

Skin.

Mr Hatchett has ascertained that they contain no phosphat of lime as a constituent part, and scarcely any saline ingredients; for when calcined they leave but a very inconsiderable residuum. Thus 250 grains of hog's bladder left only 0.02 grain of residuum †.

† Phil. Transf. 1799. p. 333.

Sect. IV. *Of the Skin.*

The skin is that strong thick covering which envelopes the whole external surface of animals. It is composed chiefly of two parts: a thin white elastic layer on the outside, which is called *epidermis*, or *cuticle*; and a much thicker layer, composed of a great many fibres, closely interwoven, and disposed in different directions; this is called the *cutis*, or *true skin*. The *epidermis* is that part of the skin which is raised in blisters.

224 Epidermis.

1. The epidermis is easily separated from the cutis by maceration in hot water. It possesses a very great degree of elasticity.

225 Its properties.

It is totally insoluble in water and in alcohol. Pure fixed alkalies dissolve it completely, as does lime likewise, though slowly ‡. Sulphuric and muriatic acids do not dissolve it, at least they have no sensible action on it for a considerable time; but nitric acid soon deprives it of its elasticity, causes it to fall to pieces, and probably soon decomposes it §.

‡ Chaptal, Ann. de Chim. xx. 221.

It is well known that the living epidermis is tinged yellow almost instantaneously by nitric acid; but this effect does not take place, at least so speedily, when the dead cuticle is plunged in nitric acid altogether ".

§ Cruikshank on Insensible Perspiration. p. 32.

226 Cutis.

2. When a portion of cu[illegible] is macerated for some hours in water, and agitation [illegible] pressure is employed to accelerate the effect, the [illegible] and all the extraneous matter with which it was [illegible] are separated from it, but its texture remai[illegible] On evaporating the water employed, [illegible] may be obtained. No [illegible] water has any farther effect [illegible] not diminished, and its [illegible] boiled in a sufficient qua[illegible] completely dissolved, and the whole of it, by evaporating the water, obtained in the state of *gelatine* *.

* Seguin, Nicholson's Journal, i. 271.

227 Composed of gelatine.

Seguin informs us that he has ascertained, by a great variety of experiments, that the cutis differs from gelatine merely in containing an additional quantity of oxygen. Hot water (he says) expels this oxygen, and thus converts cutis into gelatine †. As these experiments have not been published, it is impossible to form any judgment of their weight.

† Ibid. 272.

228 Nature of tanning.

It is the skin or cutis of animals of which leather is formed. The process of converting skin into leather is called *tanning*. This process, though practised in the earliest ages, was merely empyrical, till the happy ingenuity of Mr Seguin led him to discover its real nature. After the epidermis and all the impurities of the skin have been separated, and its pores have been so far opened as to admit of being completely penetrated, it is steeped in an infusion of oak-bark, which consists of gallic acid and tan. The gallic acid (if we believe Seguin) deprives the skin gradually of oxygen, and thus converts it into gelatine, and the tan combines with this gelatine the instant it is formed; and this process goes

Brain and Nerves.

goes on ſo ſlowly that the texture of the ſkin is not altered. Leather, therefore, is merely a combination of gelatine and tan ‡.

‡ Nicholſon's Journal, i. 171.

Sect. V. *Of the Brain and Nerves.*

The brain and nerves are the inſtruments of ſenſation, and even of motion; for an animal loſes the power of moving a part the inſtant that the nerves which enter it are cut.

The brain and nerves have a ſtrong reſemblance to each other; and it is probable that they agree alſo in their compoſition. But hitherto no attempt has been made to analyſe the nerves. The only chemiſts who have examined the nature of *brain* are Mr Thouret * and Mr Fourcroy ‡.

* Jour. de Phyſ. xxxviii 329; Ann de Chim. xvi. 282.

The brain conſiſts of two ſubſtances, which differ from each other ſomewhat in colour, but which, in other reſpects, ſeem to be of the ſame nature. The outermoſt matter, having ſome ſmall reſemblance in colour to wood-aſhes, has been called the *cineritious* part; the innermoſt part has been called the *medullary* part.

229. Properties of brain.

Brain has a ſoft feel, not unlike that of ſoap; its texture appears to be very cloſe; its ſpecific gravity is greater than that of water.

When brain is kept in cloſe veſſels ſo that the external air is excluded, it remains for a long time unaltered. Fourcroy filled a glaſs veſſel almoſt completely with pieces of brain, and attached it to a pneumatic apparatus; a few bubbles of carbonic acid gas appeared at firſt, but it remained above a year without undergoing any farther change ‡.

‡ Ibid. 297.

This is very far from being the caſe with brain expoſed to the atmoſphere. In a few days (at the temperature of 60°) it exhales a moſt deteſtable odour, becomes acid, aſſumes a green colour, and very ſoon a great quantity of ammonia makes its appearance in it.

Cold water does not diſſolve any part of the brain; but by trituration in a mortar it forms with water a whitiſh coloured emulſion, which appears homogeneous, may be paſſed through a filter, and the brain does not precipitate by reſt. When this emulſion is heated to 145°, a white coagulum is formed. The addition of a great quantity of water alſo cauſes a coagulum to appear, which ſwims on the ſurface, but the water ſtill retains a milky colour. When ſulphuric acid is dropt into the watery emulſion of brain, white flakes ſeparate and ſwim on the ſurface, and the liquid becomes red. Nitric acid produces the ſame effects, only the liquid becomes yellow. Alcohol alſo ſeparates a white coagulum from the emulſion, after it has been mixed with it for ſome hours. When nitric acid is added to the emulſion till it becomes ſlightly acid, a coagulum is alſo ſeparated. This coagulum is of a white colour; it is inſoluble in water and in alcohol. Heat ſoftens, but does not melt it. When dried, it becomes tranſparent, and breaks with a glaſſy fracture. It has therefore ſome reſemblance to *albumen* §.

§ Ibid. 288.

When brain is triturated in a mortar with diluted ſulphuric acid, part is diſſolved, the reſt may be ſeparated, by filtration, in the form of a coagulum. The clear. The brain is completely decompoſed, a quantity of ammonia combines with the acid and forms ſulphat of ammonia, while charcoal is precipitated. The water, by evaporation and treatment with alcohol, yields ſulphats of ammonia and lime, phoſphoric acid, and phoſphats of ſoda and ammonia. Brain therefore contains

Its analyſis.

Phoſphat of lime,
———— ſoda,
———— ammonia.

Traces alſo of ſulphat of lime can be diſcovered in it. The quantity of theſe ſalts is very ſmall; altogether they do not amount to $\frac{1}{100}$th part ||.

|| Ann. de Chim. xvi. 288.

Diluted nitric acid, when triturated with brain, likewiſe diſſolves a part, and coagulates the reſt. The ſolution is tranſparent. When evaporated till the acid becomes concentrated, carbonic acid gas and nitrous gas are diſengaged; an efferveſcence takes place, white fumes appear, an immenſe quantity of ammonia is diſengaged, a bulky charcoal remains mixed with a conſiderable quantity of oxalic acid *.

* Ibid 307.

When brain is gradually evaporated to dryneſs by the heat of a water bath, a portion of tranſparent liquid ſeparates at firſt from the reſt, and the reſiduum, when nearly dry, acquires a brown colour; its weight amounts to about one-fourth of the freſh brain. It may ſtill be formed into an emulſion with water, but very ſoon ſeparates again ſpontaneouſly.

When alcohol is repeatedly boiled upon this dried reſiduum till it ceaſes to have any more action, it diſſolves about five eighths of the whole. When this alcohol cools, it depoſits a yellowiſh white ſubſtance, compoſed of brilliant plates. When kneaded together by the fingers, it aſſumes the appearance of a ductile paſte: at the temperature of boiling water it becomes ſoft, and when the heat is increaſed it blackens, exhales empyreumatic and ammoniacal fumes, and leaves behind it a charry matter †. When the alcohol is evaporated, it depoſites a yellowiſh black matter, which reddens paper tinged with turnſol, and readily diffuſes itſelf through water ‡.

† ... 310.

‡ Ibid

Pure concentrated potaſs diſſolves brain, diſengaging a great quantity of ammonia.

Theſe facts are ſufficient to ſhew us, that, excluſive of the ſmall proportion of ſaline ingredients, brain is compoſed of a peculiar matter, differing in many particulars from all other animal ſubſtances, but having a conſiderable reſemblance in many of its properties to albumen. Brain has been compared to a ſoap; but it is plain that the reſemblance is very faint, as ſcarcely any oily matter could be extricated from brain by Fourcroy, though he attempted it by all the contrivances which the preſent ſtate of chemiſtry ſuggeſted; and the alkaline proportion of it is a great deal too ſmall to merit any attention.

Sect. VI. *Of Nails, Horns, Hair, Feathers.*

These ſubſtances have not hitherto been analyſed. We know only that they have a great reſemblance to each other. They give out the ſame ſmell, and exhibit the ſame phenomena when burnt, and they yield the

Book I.

a species of soap. When muriatic acid is poured into the solution of these substances in pure soda, a quantity of sulphurated hydrogen gas is disengaged, and a black substance, doubtless charcoal, precipitates. Hence it follows that these substances contain in their composition a quantity of sulphur. Accordingly, if a bit of silver is put into the solution, it instantly assumes a black colour §.

These substances scarcely contain any earthy ingredients. One hundred grains of ox horn, after calcination, left only 0.04 grain of residuum, half of which was phosphat of lime. Seventy-eight grains of chamois horn left five grains of residuum ||.

§ Merat-Guillot, Ann. de Chim. xxxiv.

|| Hatchett, Phil. Trans. 1799, p.

Such is a very imperfect account of the solids which compose animal bodies. We proceed next to the fluid which circulates through living bodies, namely *blood*; and to the various *secretions* formed from the blood, either in order to answer some important purpose to the animal, or to be evacuated as useless, that the blood thus purified may be more proper for answering the ends for which it is destined. Many of these substances have been examined with more care by chemists than the animal solids.

Sect. VII. *Of Blood.*

Blood

Blood is a well known fluid, which circulates in the veins and arteries of the more perfect animals. It is of a red colour, has a considerable degree of consistency, and an unctuous feel, as if it contained a quantity of soap. Its taste is slightly saline, and it has a peculiar smell.

The specific gravity of human blood is, at a medium, 1.0527 *. Mr Fourcroy found the specific gravity of bullock's blood, at the temperature of 60°, to be 1.056 †. The blood does not uniformly retain the same consistence in the same animal, and its consistence in different animals is very various. It is easy to see that its specific gravity must be equally various.

* Haller's Physiology, ii. 41.

† Ann. de Chim. vii. 147.

232
Composed of red globules,

When the blood is viewed through a microscope, a great many globules, of a red colour, are seen floating in it. It is to these globules that the red colour of the blood is owing. They were first examined with attention by Leuwenhoeck. Their form, their proportion, and the changes which they undergo from the addition of various substances, have been examined with the greatest care; but hitherto without adding much to our knowledge. We neither know the ingredients of which the red globules are composed, nor the changes to which they are subjected, nor the useful purposes which they serve; nor has any accurate method been discovered of separating them from the rest of the blood, and of obtaining them in a state of purity.

When blood, after being drawn from an animal, is allowed to remain for some time at rest, it very soon coagulates into a solid mass, of the consistence of curdled milk. This mass gradually separates into two parts: one of which is fluid, and is called *serum*; the other, the coagulum, has been called *cruor*, because it alone retains the red colour which distinguishes blood. This separation is very similar to the separation of curdled milk into curds and whey. The cruor usually sinks to the bottom of the vessel, and, of course, is covered by the serum.

233

The cruor, or *clot* as it is sometimes called, is of a red colour, and possesses considerable consistence. Its mean specific gravity is about 1.245 ‡. If we wash the cruor in a sufficient quantity of water, it gradually loses its red colour, and assumes the appearance of a whitish, fibrous, elastic mass, which possesses all the properties of *fibrina*. The cruor therefore is composed chiefly of fibrina. The water in which it has been washed assumes a red colour, but continues transparent. It is evident from this, that it contains, dissolved in it, the red globules; not, however, in a state of purity, for it is impossible to separate the cruor completely from the serum: consequently the water must contain both serum and red globules. We know, however, from this, that the red globules are soluble in water. The cruor of the blood, then, is composed of red globules and fibrina.

Blood

‡ Jurin, Haller's Physiolog. ii. 41.

If the cruor of the blood be exposed to a gentle heat, it becomes gradually dry and brittle. If this dry mass be submitted to distillation, it yields water, ammonia, a thick empyreumatic oil, and much carbonat of ammonia: there remains a spongy coal of a brilliant appearance, from which sulphuric acid extracts *soda* and *iron*; there remains behind a mixture of phosphat of lime and charcoal ||.

|| Fourcroy iii. 207.

When the fibrina is distilled, it yields precisely the same products; but the residuum contains neither iron nor soda. The red water, on the contrary, which had been employed to wash the cruor, contains both of these substances, especially iron; which may be obtained in the state of oxyd by evaporating this water to dryness, and calcining the residuum ¶. These facts are sufficient to demonstrate that the red globules contain iron; consequently the opinion that their colour depends upon that metal is at least possible. It is probably owing to the soda which it contains, that the presence of iron cannot be ascertained in the solution of these globules by the usual tests. The prussian alkali causes no precipitate; the infusion of nut-galls gives it no blue or purplish tinge *.

¶ Ibid.

* Wells, Phil. Trans. 1797.

234
And serum.

The serum is of a light greenish yellow colour; it has the taste, smell, and feel of the blood, but its consistence is not so great. Its mean specific gravity is about 1.0287 †. It converts syrup of violets to a green, and therefore contains an alkali. On examination, it is found that it owes this property to a portion of soda. When heated to the temperature of 156° §, the serum coagulates, as Harvey first discovered ‡. It coagulates also when boiling water is mixed with it; but if serum be mixed with six parts of cold water, it does not coagulate by heat ‡. When thus coagulated, it has a greyish white colour, and is not unlike the boiled white of an egg §. If the coagulum be cut into small pieces, a muddy fluid may be squeezed from it, which has been termed the *serosity*. After the separation of this fluid, if the residuum be carefully washed in boiling water and examined, it will be found to possess all the properties of *albumen*. The serum, therefore, contains a considerable proportion of albumen. Hence its coagulation by heat, and the other phenomena which albumen usually exhibits.

† Jurin, Haller's Physiology, ii. 41.

§ Cullen.

‡ De Gener. Anim. p. 161.

‡ Fourcroy, Ann. de Chim vii. 157.

§ Ibid. 156.

If the serosity be gently evaporated till it becomes concentrated, and then be allowed to cool, it assumes the form of a jelly, as was first observed by De Haen ||. Consequently it contains *gelatine*.

|| Ibid. 157.

If serum be mixed with twice its weight of water, and, after coagulation by heat, the albumen be separated

Blood.

ted by filtration, and the liquid be slowly evaporated till it is considerably concentrated, a number of crystals are deposited when the liquid is left standing in a cool place. These crystals consist of muriat of soda and carbonat of soda ¶.

. Thus it appears that the serum of the blood contains albumen, gelatine, soda, muriat of soda, and carbonat of soda, besides a portion of water.

¶ Fourcroy, Ann. de Chim. vii 158.

Gelatine may be precipitated from the serosity by the three mineral acids. Mr Hunter observed, that Goulard's extract, or, which is the same thing, acetite of lead dissolved in acetous acid, produces with gelatine a copious precipitate ¶. When nitric acid is distilled off serum, it converts it partly into prussic acid *. Acids, alcohol, and tan, precipitate the albumen in different states; but this, after what has been said in the last chapter, section ii. requires no farther explanation.

¶ On the Blood, 35

* Fourcroy, Ann. de Chim. vi. 180.

The proportion between the cruor and serum of the blood varies much in different animals, and even in the same animal in different circumstances. The most common proportion is about one part of cruor to three parts of serum; but in many cases the cruor exceeds and falls short of this quantity: the limits of the ratios of these substances to each other appear, from a comparison of the conclusions of most of those who have written accurately on the subject, to be 1 : 1 and 1 : 4; but the first case must be very rare indeed *.

* Haller's Physiology, ii. 47.

When new-drawn blood is stirred briskly round with a stick, or the hand, the whole of the fibrina collects together upon the stick, and in this manner may be separated altogether from the rest of the blood. The red globules, in this case, remain behind in the serum. It is in this manner that the blood is prepared for the different purposes to which it is put, as clarifying sugar, making puddings, &c. After the fibrina is thus separated, the blood no longer coagulates when allowed to remain at rest, but a spongy flaky matter separates from it and swims on the surface †.

† Fourcroy, Ann. de Chim. vii. 146.

When blood is dried by a gentle heat, water exhales from it, retaining a very small quantity of animal matter in solution, and consequently having the odour of blood. Blood dried in this manner being introduced into a retort and distilled, there comes over, first a clear watery liquor, then carbonic acid gas and carbonat of ammonia, which crystallizes in the neck of the retort; after these products there comes over a fluid oil, carbonated hydrogen gas, and an oily substance of the consistence of butter. The watery liquor possesses the property of precipitating from sulphat of iron a green powder: muriatic acid dissolves part of this powder, and there remains behind a little prussian blue. Consequently this watery liquor contains both an alkali and prussic acid ‡.

‡ Ibid. 153.

9216 grains of dried blood being put into a large crucible, and gradually heated, at first became nearly fluid, and swelled up considerably, emitted a great many fetid fumes of a yellowish colour, and at last took fire and burned with a white flame, evidently owing to the presence of oil. After the flame and the fumes had disappeared, a light smoke was emitted, which affected the eyes and the nose, which had the odour of prussic acid, and reddened moist papers stained with vegetable blues. At the end of six hours, when the matter had lost five sixths of its substance, it melted anew, exhibited a purple flame on its surface, and emitted a thick smoke. This smoke affected the eyes and nostrils, and reddened blue paper, but it had not the smell of prussic acid. When a quantity of it was collected and examined, it was found to possess the properties of phosphoric acid. The residuum amounted to 181 grains; it had a deep black colour, and a metallic brilliancy, and its particles were attracted by the magnet. It contained no uncombined soda, though the blood itself, before combustion, contains it abundantly; but water extracted from it muriat of soda, part of the rest was dissolved by muriatic acid, and, of course, was lime; there was besides a little silica, which had evidently been separated from the crucible. The iron had been reduced during the combustion ‡.

‡ Fourcroy, Ann. de Chim. vii. 151.

Such are the properties of blood, as far as they have been hitherto ascertained by experiment. We have seen that it contains the following ingredients:

235 Component parts of blood.

1. Water,	5. Iron,
2. Fibrina,	6. Soda,
3. Albumen,	7. Muriat of soda,
4. Gelatine,	8. Phosphat of lime.

But our knowledge of this singular fluid is by no means so complete as it ought to be; a more accurate analysis would probably discover the presence of other substances, and enable us to account for many of the properties of blood which at present are inexplicable.

It would be of great consequence also to compare together the blood of different animals, and of the same animal at different ages, and to ascertain in what particulars they differ from each other. This would probably throw light on some of the obscurest parts of the animal economy. Very little progress has hitherto been made in these researches: if we except the labours of Rouelle, who obtained nearly the same ingredients, though in different proportions, from the blood of a great variety of animals, the experiments of Fourcroy on the blood of the human fœtus are almost the only ones of that kind with which we are acquainted.

He found that it differs from the blood of the adult in three things: 1st, Its colouring matter is darker, and seems to be more abundant; 2d, It contains no fibrina, but probably a greater proportion of gelatine than blood of adults; 3d, It contains no phosphoric acid §.

Blood of the fœtus.

§ Ibid. 156.

The examination of diseased blood, too, would be of great consequence; because the difference of its properties from the blood of people in health might throw much light on the nature of the disease. It is well known, that when a person labours under inflammation, his blood is not susceptible of coagulating so soon as healthy blood. This longer time allows the red globules to sink to the bottom, and the coagulated fibrina appears at the top, of its natural whitish colour. Hence the appearance of the *buffy coat*, as it is called, which characterizes blood during inflammation.

237 Diseased blood.

During that disease which is known by the name of *diabetes*, in which the urine is excessive in quantity, and contains sugar, the serum of blood often, as appears from the experiments of Dr Dobson and Dr Rollo, assumes the appearance of whey; and, like it, seems to contain sugar, or, at least, it has lost its usual salt taste.

Fourcroy mentions a case of extreme feebleness, in which all the parts of the body were in an unusual relaxed state. In that patient a quantity of blood oozed out

out from the eye lids, which tinged linen blue, as if it had been stained with prussian blue. Here prussic alkali seems to have been formed in the blood.

SECT. VIII. *Of Milk.*

MILK is a fluid secreted by the female of all those animals denominated *mammalia*, and intended evidently for the nourishment of her offspring.

The milk of every animal has certain peculiarities which distinguish it from every other milk. But the animal whose milk is most made use of by man as an article of food, and with which, consequently, we are best acquainted, is the *cow*. Chemists, therefore, have made choice of cow's milk for their experiments. We shall at first confine ourselves to the properties and analysis of cow's milk, and afterwards point out in what respect the milk of other animals differs from it, as far at least as these differences have hitherto been ascertained.

238
Properties of milk.

Milk is an opaque fluid, of a white colour, a slight peculiar smell, and a pleasant sweetish taste. When newly drawn from the cow, it has a taste very different from that which it acquires after it has been kept for some hours.

It is liquid, and wets all those substances which can be moistened by water; but its consistence is greater than that of water, and it is slightly unctuous. Like water, it freezes when cooled down to about 30°; but Parmentier and Deyeux, to whom we are indebted for by far the completest account of milk hitherto published, found that its freezing point varies considerably in the milk of different cows, and even of the same cow at different times *. Milk boils also when sufficiently heated; but the same variation takes place in the boiling point of different milks, though it never deviates very far from the boiling point of water. Milk is specifically heavier than water, and lighter than blood; but the precise degree cannot be ascertained, because almost every particular milk has a specific gravity peculiar to itself.

* Jour. de Phys. xxxvii. 362.

When milk is allowed to remain for some time at rest, there collects on its surface a thick unctuous yellowish coloured substance, known by the name of *cream*. The cream appears sooner in milk in summer than in winter, evidently owing to the difference of temperature. In summer, about four days of repose are necessary before the whole of the cream collects on the surface of the liquid; but in winter it requires at least double the time †.

† Fourcroy, Ann. de Chim. vii. 167.

After the cream is separated, the milk which remains is much thinner than before, and it has a bluish white colour. If it be heated to the temperature of 100°, and a little *rennet*, which is water digested with the inner coat of a calf's stomach, and preserved with salt, be poured into it, coagulation ensues; and if the coagulum be broken, the milk very soon separates into two substances: a solid white part, known by the name of *curd*; and a fluid part, called *whey*.

Thus we see that milk may be easily separated into three parts; namely, *cream*, *curd*, and *whey*.

239
Cream

CREAM is of a yellow colour, and its consistence increases gradually by exposure to the atmosphere. In three or four days, it becomes so thick that the vessel which contains it may be inverted without risking any loss. In eight or ten days more its surface is covered over with mucors and byssi, and it has no longer the flavour of cream, but of very fat cheese *. This is the process for making what in this country is called a *cream cheese*.

Milk.

* Parmentier and Deyeux, Ann. de Chim. vii. 372.

Cream possesses many of the properties of an oil. It is specifically lighter than water, it has an unctuous feel, stains clothes precisely in the manner of oil; and if it be kept fluid, it contracts at last a taste which is very analogous to the rancidity of oils †. When kept boiling for some time, a little oil makes its appearance, and floats upon its surface ‡. Cream is neither soluble in alcohol nor oils §. These properties are sufficient to shew us that it contains a quantity of oil; but this oil is combined with a part of the curd, and mixed with some serum. Cream, then, is composed of a peculiar oil, curd, and serum. The oil may be easily obtained separate by agitating the cream for a considerable time. This process, known to every body, is called *churning*. After a certain time, the cream separates into two portions: one fluid, and resembling creamed milk; the other solid, and called *butter*.

† Ibid. 375.

‡ Ibid. 374.

§ Ibid.

240
Converted into butter.

Butter is of a yellow colour, possesses the properties of an oil, and mixes readily with other oily bodies. When heated to the temperature of 96°, it melts, and becomes transparent; if it be kept for some time melted, some curd and water or whey separate from it, and it assumes exactly the appearance of oil ||. But this process deprives it in a great measure of its peculiar flavour.

|| Fourcroy, Ann de Chim. vii. 170.

When butter is kept for a certain time, it becomes rancid, owing in a good measure to the [illegible] these foreign ingredients; for if butter be [illegible] and a great portion of these matters separ[illegible] not become rancid nearly so soon as when it is not treated in this manner. It was formerly supposed that this rancidity was owing to the developement of a peculiar acid; but Parmentier and Deyeux have shewn, that no acid is present in rancid butter *. When butter is distilled, there comes over water, sebacic acid, and oil, at first fluid, but afterwards concrete. The carbonaceous residuum is but small.

* Ibid. 379.

241
And how.

Butter may be obtained by agitating cream newly taken from milk, or even by agitating milk newly drawn from the cow. But it is usual to allow cream to remain for some time before it is churned. Now cream, by standing, acquires a sour taste; butter therefore is commonly made from sour cream. Fresh cream requires at least four times as much churning before it yields its butter as sour cream does †; consequently cream acquires, by being kept for some time, new properties, in consequence of which it is more easily converted into butter. When very sour cream is churned, every one who has paid the smallest attention must have perceived, that the butter-milk, after the churning, is not nearly so sour as the cream had been. The butter, in all cases, is perfectly sweet; consequently the acid which had been evolved has in a great measure disappeared during the process of churning. It has been ascertained, that cream may be churned, and butter obtained, though the contact of atmospheric air be excluded ‡. We have no doubt, that in all cases where such an experiment succeeded, the cream on which it was made had previously become sour. On the other hand, it has been ascertained, that when cream is churned in contact with air, it absorbs a considerable quantity of it §; and it cannot

† Fourcroy, ibid. 169.

‡ Young de Lacte, 15.

§ Mid-Lothian Report for 1795.

Milk.

cannot be doubted, that the portion absorbed is oxygen.

These facts are sufficient to afford us a key to explain what takes place during the process of churning. There is a peculiar oil in milk, which has so strong an affinity for the other ingredients, that it will not separate from them spontaneously; but it has an affinity for oxygen, and when combined with it, forms the concrete body called *butter*. Agitation produces this combination of the oil with oxygen; either by causing it to absorb oxygen from the air, or, if that be impossible, by separating it from the acid which exists in sour cream. Hence the absorption of air during churning; hence also the increase of temperature of the cream, which Dr Young found to amount constantly to 4°; and hence the sweetness of the butter-milk compared with the cream from which it was obtained.

The affinity of the oil of cream for the other ingredients is such, that it never separates completely from them. Not only is curd and whey always found in the cream, but some of this oil is constantly found in creamed milk and even in whey: for it has been ascertained by actual experiment, that butter may be obtained by churning whey; 27 Scotch pints of whey yield at an average about a pound of butter ||. This accounts for a fact well known to those who superintend dairies, that a good deal more butter may be obtained from the same quantity of milk, provided it be churned as drawn from the cow, than when the cream alone is collected and churned.

|| Mid-Lothian Report, 1795.

The butter-milk, as Parmentier and Deyeux ascertained by experiment, possesses precisely the properties of milk deprived of cream ¶.

¶ Ann. de Chim. vii. 379.

273
Properties of curd.

CURD, which may be separated from creamed milk by rennet, has all the properties of coagulated albumen. It is white and solid; and when all the moisture is squeezed out, it has a good deal of brittleness. It is insoluble in water; but pure alkalies and lime dissolve it readily, especially when assisted by heat; and when fixed alkali is used, a great quantity of ammonia is emitted during the solution. The solution of curd in soda is of a red colour, at least if heat be employed; owing probably to the separation of charcoal from the curd by the action of the alkali *. Indeed, when a strong heat has been used, charcoal precipitates as the solution cools †. The matter dissolved by the alkali may be separated from it by means of any acid; but it has lost all the properties of curd. It is of a black colour, melts like tallow by the application of heat, leaves oily stains on paper, and never acquires the consistence of curd ‡. Hence it appears that curd, by the action of a fixed alkali, is decomposed, and converted into two new substances, ammonia, and oil or rather fat.

* Ibid.

† Fourcroy, ibid. p. 175.

‡ Ibid.

Curd is soluble also in acids. If, over curd newly precipitated from milk, and not dried, there be poured eight parts of water, containing as much of any of the mineral acids as gives it a sensibly acid taste, the whole is dissolved after a little boiling §. Acetous acid and lactic acid do not dissolve curd when very much diluted ||. But these acids, when concentrated, dissolve it readily, and in considerable quantity ¶. It is remarkable enough, that concentrated vegetable acids dissolve curd readily, but have very little action on it when they are very much diluted: whereas the mineral dissolve it when much diluted; but when concentrated, have either very little effect on it, as sulphuric acid *; or decompose it, as nitric acid. By means of this last acid, as Berthollet discovered, a quantity of azotic gas may be obtained from curd.

§ Scheele, ii. 53.

|| Ibid.

¶ Parmentier and Deyeux, ibid. 417. Fourcroy, ibid. p. 173.

* Parmentier, ibid.

Curd, as is well known, is used in making *cheese*; and the cheese is the better the more it contains of cream, or of that oily matter which constitutes cream. It is well known to cheesemakers, that the goodness of it depends in a great measure on the manner of separating the whey from the curd. If the milk be much heated, the coagulum broken in pieces, and the whey forcibly separated, as is the practice in many parts of Scotland, the cheese is scarce good for any thing; but the whey is delicious, especially the last squeezed-out whey, and butter may be obtained from it in considerable quantity. A full proof that nearly the whole creamy part of the milk has been separated with the whey. Whereas if the milk be not too much heated (about 100° is sufficient), if the coagulum be allowed to remain unbroken, and the whey be separated by very slow and gentle pressure, the cheese is excellent; but the whey is almost transparent, and nearly colourless.

Of cheese.

Good cheese melts at a moderate heat; but bad cheese, when heated, dries, curls, and exhibits all the phenomena of burning horn. Hence it is evident, that all the properties in which curd differs from albumen are owing to its containing combined with it a quantity of the peculiar oil which constitutes the distinguishing characteristic of cream; hence its flavour and smell; and hence also the white colour of milk.

This sameness of curd and albumen shews us, that the coagulation of milk and of albumen depend upon the same cause. Heat, indeed, does not coagulate milk, because the albumen in it is diluted with too large a quantity of water. But if milk be boiled in contact with air, a pellicle soon forms on its surface, which has the properties of coagulated albumen: if this pellicle be removed, another succeeds; and by continuing the boiling, the whole of the albuminous or curdy matter may be separated from milk *. When this pellicle is allowed to remain, it falls at last to the bottom of the vessel, where, being exposed to a greater heat, it becomes brown, and communicates to milk that disagreeable taste which, in this country is called a *singed* taste. It happens more readily when milk is boiled along with rice, flour, &c.

274
Coagulation of milk.

* Parmentier, ibid. p. 415.

If to boiling milk there be added as much of any neutral salt as it is capable of dissolving, or of sugar, or of gum arabic, the milk coagulates, and the curd separates †. Alcohol also coagulates milk ‡; as do all acids, rennet, and the infusion of the flowers of artichoke, and of the thistle ||. If milk be diluted with ten times its weight of water, it cannot be made to coagulate at all ¶.

† Scheele, ii. 52.

‡ Parmentier, ibid. p. 416.

|| Ibid.

¶ Scheele, ii. 54.

275
Properties of whey.

WHEY, after being filtered, to separate a quantity of curd which still continues to float through it, is a thin pellucid fluid, of a yellowish green colour and pleasant sweetish taste, in which the flavour of milk may be distinguished. It always contains some curd; but nearly the whole may be separated by keeping the whey for some time boiling; a thick white scum gathers on the surface, which in Scotland is known by the name of *float whey*. When this scum, which consists of the curdy part, is carefully separated, the whey, after being allowed to remain at rest for some hours, to give the remainder

Milk.

remainder of the curd time to precipitate, is decanted off, almost as colourless as water, and scarcely any of the peculiar taste of milk can be distinguished in it. If it be now slowly evaporated, it deposites at last a number of white coloured crystals, which are *sugar of milk*. Towards the end of the evaporation, some crystals of muriat of potass and of muriat of lime make their appearance *. According to Scheele, it contains also a little phosphat of lime †.

After the salts have been obtained from whey, what remains concretes into a jelly on cooling ‡. Hence it follows, that whey also contains *gelatine*. Whey, then, is composed of water, sugar of milk, gelatine, muriat of potass, and muriat of lime. The other salts, which are sometimes found in it, are only accidentally present.

If whey be allowed to remain for some time, it becomes sour, owing to the formation of a peculiar acid known by the name of *lactic acid*. It is to this property of whey that we are to ascribe the acidity which milk contracts; for neither curd nor cream, perfectly freed from serum, seem susceptible of acquiring acid properties. Hence the reason, also, that milk, after it become sour, always coagulates. Boiled milk has the property of continuing longer sweet; but it is singular enough, that it runs sooner to putrefaction than ordinary milk *.

* Parmentier, p. 417.
† Scheele, ii. 61.
‡ Rouelle.
* Parmentier, ibid. p. 343.

276
Vinegar obtained from milk.

The acid of milk differs considerably from the acetous; yet vinegar may be obtained from milk by a very simple process. If to somewhat more than 8 lbs. troy of milk, six spoonfuls of alcohol be added, and the mixture well corked be exposed to a heat sufficient to support fermentation (provided attention be paid to allow the carbonic acid gas to escape from time to time), the whey, in about a month, will be found converted into vinegar †.

† Scheele, ii. 68.

277
Milk undergoes fermentation.

Milk is almost the only animal substance which may be made to undergo the vinous fermentation, and to afford a liquor resembling wine or beer, from which alcohol may be separated by distillation. This singular fact seems to have been first discovered by the Tartars; they obtain all their spirituous liquors from mares milk. It has been ascertained, that milk is incapable of being converted into wine till it has become sour; after this, nothing is necessary but to place it in the proper temperature, the fermentation begins of its own accord, and continues till the formation of wine be completed ‡. Scheele had observed, that milk was capable of fermenting, and that a great quantity of carbonic acid gas was extricated from it during this fermentation ‖. But he did not suspect, that the result of this fermentation was the formation of an intoxicating liquor similar to wine.

‡ Parmentier, 361.
‖ Scheele, 66.

When milk is distilled by the heat of a water bath, there comes over water, having the peculiar odour of milk; which putrifies, and consequently contains, besides mere water, some of the other constituent parts of milk. After some time, the milk coagulates ¶, as always happens when hot albumen acquires a certain degree of concentration. There remains behind a thick unctuous yellowish white substance, to which Hoffman gave the name of *frangipane*. This substance, when the fire is increased, yields at first a transparent liquid, which becomes gradually more coloured; some very fluid oil comes over, then ammonia, an acid, and at last a very thick black oil. Towards the end of the process carbonated hydrogen gas is disengaged *. There remains in the retort a coal which contains carbonat of potass, muriat of potass, and phosphat of lime, and sometimes magnesia, iron, and muriat of soda †.

¶ Bouquet.
* Parmentier, ibid. p. 368.
† Mem. Med. Par. 1787. p. 607.

278
Its component parts.

Thus we see, that cows milk is composed of the following ingredients.

1. Water,	5. Sugar of milk,
2. Oil,	6. Muriat of lime,
3. Albumen,	7. Muriat of potass,
4. Gelatine,	8. Sulphur.

The milk of all other animals, as far as it has hitherto been examined, consists nearly of the same ingredients; but there is a very great difference in their portion.

279
Woman's milk.

Woman's milk has a much sweeter taste than cows milk. When allowed to remain at rest for a sufficient time, a cream gathers on its surface. This cream is more abundant than in cows milk, and its colour is usually much whiter. After it is separated, the milk is exceedingly thin, and has the appearance rather of whey, with a bluish white colour, than of creamed milk. None of the methods by which cows milk is coagulated succeed in producing the coagulation of woman's milk *. It is certain, however, that it contains curd; for if it be boiled, pellicles form on its surface, which have all the properties of curd †. Its not coagulating, therefore, must be attributed to the great quantity of water with which the curd is diluted.

* Clarke, Irish Trans. ii. 175.
† Parmentier, ibid. p. 419.

Though the cream be churned ever so long, no butter can be obtained from it; but if, after being agitated for some hours, it be allowed to remain at rest for a day or two, it separates into two parts; a fluid which occupies the inferior part of the vessel, pellucid, and colourless, like water and a thick white unctuous fluid, which swims on the surface. The lowermost fluid contains sugar of milk and some curd; the uppermost does not differ from cream except in consistence. The oily part of the cream, then, cannot be separated by agitation from the curd ‡. This cream [illegible] portion of curd than the cream of cows milk [illegible]

When this milk, after the curd is [illegible] is slowly evaporated, it yields crystals [illegible] and of muriat of soda. The quantity of sugar is rather greater than in cow's milk. According to Haller, the sugar obtained from cow's milk is to that obtained from an equal quantity of woman's milk as 35 : 58, and sometimes as 37 : 67, and in all the intermediate ratios.

Thus it appears, that woman's milk differs from that of cows in three particulars.

280
Its peculiarities.

1. It contains a much smaller quantity of curd.
2. Its oil is so intimately combined with its curd, that it does not yield butter.
3. It contains rather more sugar of milk.

Parmentier and Deyeux ascertained, that the quantity of curd in woman's milk increases in proportion to the time after delivery ‖. Nearly the same thing has been observed with respect to cow's milk.

‖ Ibid. p. 420.

281
Asses milk.

Asses milk has a very strong resemblance to human milk: it has nearly the same colour, smell, and consistence. When left at rest for a sufficient time, a cream forms upon its surface, but by no means in such abundance as in woman's milk. This cream, by very long agitation, yields a butter, which is always soft, white, and tasteless; and, what is singular, very readily mixes again with the butter-milk; but it may be again separated

Milk, Saliva

rated by agitation, while the vessel, which contains it, is plunged in cold water. Creamed asses milk is thin, and has an agreeable sweetish taste. Alcohol and acids separate from it a little curd, which has but a small degree of consistence. The serum yields sugar of milk and muriat of lime *.

* Parmentier, p. 425.

Asses milk therefore differs from cows milk in three particulars.

282 Its peculiarities.

1. Its cream is less abundant and more insipid.
2. It contains less curd.
3. It contains more sugar of milk: the proportion is 35 : 80.

283 Goats milk

GOATS MILK, if we except its consistence, which is greater, does not differ much from cows milk. Like that milk, it throws up abundance of cream, from which butter is easily obtained. The creamed milk coagulates just as cows milk, and yields a greater quantity of curd. Its whey contains sugar of milk, muriat of lime, and muriat of soda †.

† Ibid p. 425.

284 Ewes milk

EWES MILK resembles almost precisely that of the cow. Its cream is rather more abundant, and yields a butter which never acquires the consistence of butter from cows milk. Its curd has a fat and viscid appearance, and is not without difficulty made to assume the consistence of the curd of cows milk. It makes excellent cheese ‡.

‡ Ibid p. 428.

285 Mares milk

MARES MILK is thinner than that of the cow, but scarcely so thin as human milk. Its cream cannot be converted into butter by agitation. The creamed milk coagulates precisely as cows milk, but the curd is not so abundant. The serum contains sugar of milk, sulphat of lime, and muriat of lime ‖.

‖ Ibid. p. 431.

SECT. IX. *Of Saliva.*

THE fluid secreted in the mouth, which flows in considerable quantity during a repast, is known by the name of *saliva*. No accurate analysis has hitherto been made of it, though it possesses some very singular properties.

286 Properties of saliva.

It is a liquid fluid like water, but much more viscid: it has neither smell nor taste.

Its specific gravity, according to Hamberger, is 1.0167 *. When agitated, it froths like all other adhesive liquids; indeed it is usually mixed with air, and has the appearance of froth.

* Haller's Phys. vi. 52.

It neither mixes readily with water nor oil †; but by trituration in a mortar, it may be mixed so with water as to pass through a filter ‡. It has a great affinity for oxygen, absorbs it readily from the air, and gives it out again to other bodies §. Hence the reason why gold or silver, triturated with saliva in a mortar, is oxydated, as Dutenner has observed; and why the killing of mercury by oils is much facilitated by spitting into the mixture ¶. Hence also, in all probability, the reason that saliva is a useful application to sores of the skin. Dogs, and several other animals, have constantly recourse to this remedy, and with much advantage.

† Narcessus. Haller, ibid p. 54.
‡ Fordyce on Digest. p. 51.
§ Fourcroy, Ann. de Chim. xxviii. 262.
¶ Ibid.

Saliva is coagulated by oxy-muriat of mercury, by alcohol, and by nitre *. Therefore, in all probability, it contains albumen and gelatine, or some analogous substances.

* Haller's Phys. vi.

When 100 parts of saliva are distilled, there come over 80 parts of water nearly pure, then a little carbonat of ammonia, some oil, and an acid, which perhaps is the prussic. The residuum amounts to about 1.56 parts, and is composed of muriat of soda and phosphat of lime †.

The *tartar* of the teeth, which is a crust deposited from saliva, consists, as Fourcroy has ascertained, of phosphat of lime.

Tartar of

The PANCREATIC JUICE has never been examined with much attention; but it does not appear, from the experiments that have been made, to differ much from saliva.

† Nat &c. as quoted by Haller, Physio. vi. 55.

SECT. X. *Of Bile.*

BILE is a liquid of a yellowish green colour, an unctuous feel, and bitter taste, is secreted by the liver; and in most animals considerable quantities of it are usually found collected in the gall bladder.

Great attention has been paid to this liquid by physicians; because the ancients were accustomed to ascribe a very great number of diseases, and even affections of the mind, to its agency. The most accurate chemical analysis of it which has hitherto appeared is that of Mr Cadet, which was published in the Memoirs of the French Academy of Sciences for the year 1767. Several important observations had been previously made on it by Boyle, Boerhaave, Verheyen, Ramsay, and Baglivi; and some facts have since been added to our chemical knowledge of bile by Maclurg and Fourcroy. The experiments have chiefly been confined to the bile of oxen, known in this country by the name of *gall*; because it is most easily procured in large quantities.

289 Properties of bile

The specific gravity of bile seems to vary, like that of all other animal fluids. According to Hartmann, it is 1.027 *. When strongly agitated, it lathers like soap; and for this reason, as well as from a medical theory concerning its use, it has been often called an *animal soap*.

* Haller's Phys. vi. 546.

It mixes readily with water in any proportion, and assumes a yellow colour: but it refuses to unite with oil when the two fluids are agitated together; the instant that they are left at rest, the oil separates and swims on the surface †.

† Ramsay, Haller, Med. Edin. ii. 459.

When muriatic acid is poured upon bile, let it be ever so fresh, an odour of sulphurated hydrogen gas is constantly exhaled ‡. When on 100 parts of ox bile four parts of strong muriatic acid are poured, the whole instantly coagulates; but in some hours the greater part becomes again fluid; and when passed through the filter it leaves 0.26 of a white matter, which has all the properties of albumen §. This matter was detected by Ramsay; who found that it could be precipitated from bile by alcohol, acetous acid, sulphat of potass, and muriat of soda *. Cadet ascertained, that 100 parts of ox bile contain about 0.52 of albumen. It is precipitated in a state of purity by oxy-muriatic acid, provided that acid be not employed in excess †.

‡ Maclurg, p. 13.

290 Its component parts.

§ Cadet, Mem. Par. 1767. p. 312.
‖ Ibid.
* Haller, Edin. ii. 415.
† Fourcroy, Ann. de Chim. vii. 176.

The muriatic acid solution, after the separation of the albumen, has a fine grass-green colour. When concentrated by some hours evaporation in a glass cucurbit on hot coals, it deposites a very copious precipitate, and loses almost the whole of its green colour. By longer evaporation, a new precipitate, similar to the first, appears, and the remaining liquid assumes the colour of beer. This precipitate possesses all the properties of the *resin of bile*. In its moist state it amounts to 10.8 parts ‡. The same substances may be obtained from bile by nitric acid; but the resin in that

‡ Cadet, ibid.

Bile, Biliary Calculi.

case has a yellow colour, and its properties are somewhat altered *.

If 100 parts of bile be gently evaporated to dryness by a very moderate heat, the dry mass only weighs 10 parts, and has a brownish black colour. When exposed to a strong heat in a crucible, this matter swells up, takes fire, and emits very thick fumes. The residuum amounts to 1.09. By lixiviation with water, 1.87 of crystallized soda may be obtained †; consequently 100 parts of bile contain, according to Mr Kirwan's table, 0.403546 of pure soda. But it is evident that, by this method, part of the soda must have been evaporated; therefore 100 parts of bile contain more than 0.403546 of soda. Besides the soda, there is found also a small portion of muriat of soda ‡.

Cadet found the residuum, after the separation of the salts, of a black colour: it gave some traces of iron. He also obtained a calcareous salt from bile, which he considered as a sulphat; but it is more than probable that it was phosphat of lime.

Cadet also obtained from bile, by evaporating the muriatic acid solution after the separation of the resin, a salt which crystallized in trapeziums; it had a sweetish taste, and was considered by him as analogous to sugar of milk *.

* Cadet, ibid. p. 343.
† Ibid p. 350.
‡ Ibid.
* Ibid. p. 342.

Thus we see that bile contains the following ingredients:

1. Water,	5. A sweetish salt,
2. Resin,	6. Muriat of soda,
3. Albumen,	7. Phosphat of lime,
4. Soda,	8. Iron.

The proportion of these ingredients has by no means been ascertained. The presence of iron has been denied in bile, because it gives no blue precipitate with prussic alkali, and because tincture of nut-galls does not give it a black colour †. But these reasons are insufficient to overturn the experiment of Cadet, who actually found it in bile.

† Maclurg, p. 56.

When four parts of vinegar and five of bile are mixed together, the mixture has a sweet taste, and does not coagulate milk. The lactic acid has precisely the same effect as vinegar ‡.

‡ Ramsay, ibid p. 462.

When bile is distilled in a water bath, it affords a transparent watery liquor, which contracts a pretty strong odour, not unlike that of musk or amber, especially if the bile has been kept for some days before it is submitted to distillation §. The residuum is of a deep brownish green; it attracts moisture from the air, and dissolves readily in water. When distilled in a retort, it affords a watery liquor of a yellowish colour, and impregnated with alkali, oil, carbonat of ammonia, carbonic acid, and hydrogen gas. The coaly residuum is easily incinerated *. Bile, exposed to a temperature between 65° and 85°, soon loses its colour and viscidity, acquires a nauseous smell, and deposites whitish mucilaginous flakes. After the putrefaction has made considerable progress, its smell becomes sweet, and resembles amber †. If bile be heated, and slightly concentrated by evaporation, it may be kept for many months without alteration ‡.

§ Fourcroy. iii. 292.
* Ibid.
† Ibid.
‡ Vauquelin

Sect. XI. *Of Biliary Calculi.*

Hard bodies sometimes form in the gall bladder, or in the duct through which the bile passes into the intestinal canal, and stop up the passage altogether. These concretions have got the name of *biliary calculi* or *gall-stones*. As they are formed in the midst of bile, and as the substances of which they are composed must be derived from the bile, it is proper to give an account of them here, because their properties cannot fail to throw some additional light on the nature of bile itself. 291

Biliary Calculi.

Biliary calculi, all of them at least which have been hitherto examined with attention, may be divided into three classes.

Biliary calculi of three kinds.

1. The first kind comprehends those which have a white colour, and a crystallized, shining, lamellated structure.

2. The second is dark coloured, and has precisely the appearance of inspissated bile. Both these kinds are combustible.

3. The third kind comprehends those gall stones which do not flame, but gradually waste away at a red heat.

We shall take a view of each of these kinds of biliary calculi in their order. For the greater part of the chemical knowledge which has been hitherto acquired of them, the world is chiefly indebted to Mr Fourcroy. 292

Properties of the first.

1. The first species of biliary calculi was pointed out for the first time by Haller, in a dissertation published in 1749. Walther afterwards added several new facts; and at last it was accurately described by Vicq d'Azyr *. It is almost always of an oval shape, sometimes as large as a pigeon's egg, but commonly about the size of a sparrow's; and for the most part only one calculus (when of this species) is found in the gall bladder at a time. It has a white colour; and when broken, presents crystalline plates or [illegible], brilliant and white like mica, and having a soft greasy feel. Sometimes its colour is yellow or greenish; and it has constantly a nucleus of inspissated bile †.

Its specific gravity is lower than that of water. Gren found the specific gravity of one [illegible] ‡.

When exposed to a heat considerably greater than that of boiling water, this crystallized substance softens and melts; and crystallizes again when the temperature is lowered §. It is altogether insoluble in water; but hot alcohol dissolves it with facility. Alcohol, of the temperature of 167°, dissolves [illegible] of its weight of this substance; but alcohol, at the temperature of 60°, scarcely dissolves any of it *. As the alcohol cools, the matter is deposited in brilliant plates resembling talc or boracic acid †. It is soluble in oil of turpentine ‡. When melted, it has the appearance of oil, and exhales the odour of melted wax: when suddenly heated, it evaporates altogether in a thick smoke. It is soluble in pure alkalies, and the solution has all the properties of a soap. Nitric acid also dissolves it; but it is precipitated unaltered by water ‡.

† Fourcroy. Ann. de Chim. iii. 249.
‡ Ann. de Chim. v. 186.
§ Fourcroy, ibid. ii. 123.
* Ibid. p. 180.
† Ibid iii. 256.
‡ Gren, ibid. v. 187.
‡ Fourcroy, ibid. iii. 247.

This matter, which is evidently the same with the crystals which Cadet obtained from bile, and which he considered as analogous to sugar of milk, has a strong resemblance to spermaceti. Like that substance, it is of an oily nature, and inflammable; but it differs from it in a variety of particulars.

Since it is contained in bile, it is not difficult to see how it may crystallize in the gall bladder if it happens to be more abundant than usual; and the consequence must

Biliary Calculi. Tears.

must be a gall-stone of this species. Fourcroy found a quantity of the same substance in the dried human liver *.

* Fourcroy, ibid, p. 140.

293 Of the second. 2. The second species of biliary calculus is of a round or polygonal shape, of a grey colour exteriorly, and brown within. It is formed of concentric layers of a matter which seems to be inspissated bile; and there is usually a nucleus of the white crystalline matter at the centre. For the most part there are many of this species of calculus in the gall-bladder together: indeed it is frequently filled with them. Their size is usually much smaller than that of the last species.

This is the most common kind of gall stone. It may be considered as a mixture of inspissated bile, and of the crystalline matter which forms the first species: and the appearance of calculi of this kind must vary considerably, according to the proportion of these ingredients.

294 Of the third. 3. Concerning the third species of gall stone, very little is known with accuracy. Dr Saunders tells us, that he has met with some gall-stones insoluble both in alcohol and oil of turpentine; some which do not flame, but become red, and consume to an ash like a charcoal † Haller quotes several examples of similar calculi ‡.

Gall-stones often occur in the inferior animals, particularly in cows and hogs; but the biliary concretions of these animals have not hitherto been examined with attention.

† On the Liver, p. 212.

‡ Physiol. vi. 567.

SECT. XII. *Of Tears.*

THAT peculiar fluid which is employed in lubricating the eye, and which is emitted in considerable quantities when we express grief by weeping, is known by the name of *tears*. For an accurate analysis of this fluid, chemistry is indebted to Messrs Fourcroy and Vauquelin. Before their dissertation, which was published in 1791, appeared, scarcely any thing was known about the nature of tears.

295 Properties of tears. The liquid called *tears* is transparent and colourless like water; it has scarcely any smell, but its taste is always perceptibly salt. Its specific gravity is somewhat greater than that of distilled water. It gives to paper, stained with the juice of the petals of mallows or violet, a permanently green colour, and therefore contains a fixed alkali *. It unites with water, whether cold or hot, in all proportions. Alkalies unite with it readily, and render it more fluid. The mineral acids produce no apparent change upon it †. Exposed to the air, this liquid gradually evaporates, and becomes thicker. When nearly reduced to a state of dryness, a number of cubic crystals form in the midst of a kind of mucilage. These crystals possess the properties of muriat of soda; only they tinge vegetable blues green, and therefore contain an excess of soda. The mucilaginous matter acquires a yellowish colour as it dries ‡.

* Fourcroy and Vauquelin, Jour. de Phys. xxxix 256.

† Ibid, p. 257.

‡ Ibid. p. 256.

This liquid boils like water, excepting that a considerable froth collects on its surface. If it be kept a sufficient time at the boiling temperature, $\frac{96}{100}$ parts of it evaporate in water; and there remain about .04 parts of a yellowish matter, which by distillation in a strong heat yield water and a little oil: the residuum consists of different saline matters §.

§ Ibid.

When alcohol is poured into this liquid, a mucilaginous matter is precipitated in the form of large white flakes. The alcohol leaves behind it, when evaporated, traces of muriat of soda and soda. The residuum which remains behind, when inspissated tears are burnt in the open air, exhibits some traces of phosphat of lime and phosphat of soda ‖.

‖ Fourcroy and Vauquelin, Jour. de Phys. p. 259.

Thus it appears that tears are composed of the following ingredients:

296 Component parts.

1. Water,
2. Mucilage,
3. Muriat of soda,
4. Soda,
5. Phosphat of lime,
6. Phosphat of soda,

The saline parts amount only to about 0.01 of the whole, or probably not so much.

The *mucilage* contained in the tears has the property of absorbing oxygen gradually from the atmosphere, and of becoming thick and viscid, and of a yellow colour. It is then insoluble in water, and remains long suspended in it without alteration. When a sufficient quantity of oxy muriatic acid is poured into tears, a yellow flaky precipitate appears absolutely similar to this inspissated mucilage The oxy-muriatic acid loses its peculiar odour; hence it is evident that it has given out oxygen to the mucilage. The property which this mucilage has of absorbing oxygen, and of acquiring new qualities, explains the changes which take place in tears which are exposed for a long time to the action of the atmosphere, as is the case in those persons who labour under a fistula lachrymalis *.

* Ibid. p. 257.

297 Mucus of the nose. The MUCUS of the nose has also been examined by Fourcroy and Vauquelin. They found it composed of precisely the same ingredients with the tears As this fluid is more exposed to the action of the air than the tears, in most cases its mucilage has undergone less or more of that change which is the consequence of the absorption of oxygen. Hence the reason of the greater viscidity and consistence of the mucus of the nose; hence also the great consistence which it acquires during colds, where the action of the atmosphere is assisted by the increased action of the parts †.

† Ibid. p. 258.

SECT. XIII. *Of Sinovia.*

WITHIN the capsular ligament of the different joints of the body, there is contained a peculiar liquid, intended evidently to lubricate the parts, and to facilitate their motion. This liquid is known among anatomists by the name of *sinovia*.

Whether it be the same in different animals, or even in all the different joints of the same animal, has not been determined; as no accurate analysis of the sinovia of different animals has been attempted. The only analysis of sinovia which has hitherto appeared is that by Mr Margueron, which was published in the 14th volume of the *Annales de Chimie*. He made use of sinovia obtained from the joints of the lower extremities of oxen.

298 Sinovia of the ox. The sinovia of the ox, when it has just flowed from the joint, is a viscid semi-transparent fluid, of a greenish white colour, and a smell not unlike frog spawn. It very soon acquires the consistence of jelly; and this happens equally whether it be kept in a cold or a hot temperature, whether it be exposed to the air or excluded from it. This consistence does not continue long; the sinovia soon recovers again its fluidity, and at the same time deposites a thready-like matter *.

* Margueron, Ann. de Chim. xiv. 124.

299 Its properties. Sinovia mixes readily with water, and imparts to that liquid a great deal of viscidity. The mixture froths when agitated; becomes milky when boiled, and

and deposites some pellicles on the sides of the dish; but its viscidity is not diminished †.

When alcohol is poured into sinovia, a white substance precipitates, which has all the properties of albumen. One hundred parts of sinovia contain 4.52 of albumen. The liquid still continues as viscid as ever; but if acetous acid be poured into it, the viscidity disappears altogether, the liquid becomes transparent, and deposites a quantity of matter in white threads, which possesses the following properties:

† Margueron, Ann. de Chim. xiv 126.

300 Its component parts

1. It has the colour, smell, taste, and elasticity of vegetable gluten.

2. It is soluble in concentrated acids and pure alkalies.

3. It is soluble in cold water, the solution frothes; acids and alcohol precipitate the fibrous matter in flakes. One hundred parts of sinovia contain 11.86 of this matter ‡.

‡ Ibid. p. 126—130.

When the liquid, after these substances have been separated from it, is concentrated by evaporation, it deposites crystals of acetite of soda. Sinovia, therefore, contains *soda*. Margueron found that 100 parts of sinovia contained about 0.71 of soda.

When strong sulphuric, muriatic, nitric, acetic, or sulphurous acid is poured into sinovia, a number of white flakes precipitate at first, but they are soon redissolved, and the viscidity of the liquid continues. When these acids are diluted with five times their weight of water, they diminish the transparency of sinovia, but not its viscidity; but when they are so much diluted that their acid taste is just perceptible, they precipitate the peculiar thready matter, and the viscidity of the sinovia disappears §.

§ Ibid. 127.

When sinovia is exposed to a dry atmosphere it gradually evaporates, and a scaly residuum remains, in which cubic crystals, and a white saline efflorescence, are apparent. The cubic crystals are muriat of soda. One hundred parts of sinovia contain about 1.75 of this salt. The saline efflorescence is carbonat of soda ||.

|| Ibid. 125.

Sinovia soon putrefies in a moist atmosphere, and during the putrefaction ammonia is exhaled. When sinovia is distilled in a retort there comes over, first water, which soon putrefies; then water containing ammonia; then empyreumatic oil and carbonat of ammonia. From the residuum muriat and carbonat of soda may be extracted by lixiviation. The coal contains some phosphat of lime ¶.

¶ Ibid. 128.

From the analysis of Mr Margueron it appears that sinovia is composed of the following ingredients:

11.86	fibrous matter,
4.52	albumen,
1.75	muriat of soda,
.71	soda,
.70	phosphat of lime (N),
80.57	water,
100.00.	

SECT. XIV. *Of Semen.*

THE peculiar liquid secreted in the testes of males, and destined for the impregnation of females, is known by the name of *semen*. The human semen alone has hitherto been subjected to chemical analysis. Nothing is known concerning the seminal fluid of other animals. Vauquelin published an analysis of the human semen in 1791.

Semen.

301 Properties of semen.

Semen, when newly ejected, is evidently a mixture of two different substances: the one, fluid and milky, which is supposed to be secreted by the prostate gland; the other, which is considered as the true secretion of the testes, is a thick mucilaginous substance, in which numerous white shining filaments may be discovered *. It has a slight disagreeable odour, an acrid irritating taste, and its specific gravity is greater than that of water. When rubbed in a mortar it becomes frothy, and of the consistence of pomatum, in consequence of its enveloping a great number of air bubbles. It converts paper stained with the blossoms of mallows or violets to a green colour, and consequently contains an alkali †.

* Vauquelin, Ann. de Chim. ix. 64.

† Ibid. p. 63.

As the liquid cools, the mucilaginous part becomes transparent, and acquires greater consistency; but in about twenty minutes after its emission, the whole becomes perfectly liquid. This liquefaction is not owing to the absorption of moisture from the air, for it loses instead of acquiring weight during its exposure to the atmosphere; nor is it owing to the action of the air, for it takes place equally in close vessels ‡.

‡ Ibid. p. 66.

Semen is insoluble in water before this spontaneous liquefaction, but afterwards it dissolves readily in it. When alcohol or oxy-muriatic acid is poured into this solution, a number of white flakes are precipitated §. Concentrated alkalies facilitate its combination with water. Acids readily dissolve the semen, and the solution is not decomposed by alkalies; neither indeed is the alkaline solution decomposed by acids ||.

§ Ibid. p. 70.

|| Ibid. p. 71.

Lime disengages no ammonia from fresh semen; but after that fluid has remained for some time in a moist and warm atmosphere, lime separates a great quantity from it. Consequently ammonia is formed during the exposure of semen to air ¶.

¶ Ibid. p.

302 Its component parts.

When oxy-muriatic acid is poured into semen, a number of white flakes precipitate, and the acid loses its peculiar odour. These flakes are insoluble in water, and even in acids. If the quantity of acid be sufficient, the semen acquires a yellow colour. Thus it appears that semen contains a mucilaginous substance, analogous to that of the tears, which coagulates by absorbing oxygen. Mr Vauquelin obtained from 100 parts of semen six parts of this mucilage.

When semen is exposed to the air about the temperature of 60°, it becomes gradually covered with a transparent pellicle, and in three or four days deposites small transparent crystals, often crossing each other in such a manner as to represent the spokes of a wheel. These crystals, when viewed through a microscope, appear to be four-sided prisms, terminated by very long four sided pyramids. They may be separated by diluting the liquid with water, and decanting it off. They have all the properties of phosphat of lime *. If, after the appearance of these crystals, the semen be still allowed to remain exposed to the atmosphere, the pellicle on

* Ibid. p. 67 and 73.

(N) Mr Hatchett found only 0.208 of phosphat of lime in the sinovia which he examined. He found, however, traces of some other phosphat; probably phosphat of soda. *Phil. Trans.* 1799, p. 246.

on its surface gradually thickens, and a number of white round bodies appear on different parts of it. These bodies also are phosphat of lime, prevented from crystallizing regularly by the too rapid abstraction of moisture. Mr Vauquelin found that 100 parts of semen contain three parts of phosphat of lime †. If at this period of the evaporation the air becomes moist, other crystals appear in the semen, which have the properties of carbonat of soda. The evaporation does not go on to complete exsiccation, unless at the temperature of 77°, and when the air is very dry. When all the moisture is evaporated, the semen has lost 0.9 of its weight, the residuum is semi transparent like horn, and brittle ‡.

† Vauquelin, Ann. de Chim. p 68.

‡ Ibid.

When semen is kept in very moist air, at the temperature of about 77°, it acquires a yellow colour, like that of the yolk of an egg; its taste becomes acid, it exhales the odour of putrid fish, and its surface is covered with abundance of the byssus septica §.

§ Ibid.

When dried semen is exposed to heat in a crucible, it melts, acquires a brown colour, and exhales a yellow fume, having the odour of burnt horn. When the heat is raised, the matter swells, becomes black, and gives out a strong odour of ammonia. When the odour of ammonia disappears, if the matter be lixiviated with water, an alkaline solution may be obtained, which, by evaporation, yields crystals of carbonat of soda. Mr Vauquelin found that 100 parts of semen contain one part of soda ¶. If the residuum be incinerated, there will remain only a quantity of white ashes, consisting of phosphat of lime.

¶ Ibid. p. 75.

Thus it appears that semen is composed of the following ingredients:

90 water,
6 mucilage,
3 phosphat of lime,
1 soda,

———

100

Sect. XV. Liquor of the Amnios.

The fœtus in the uterus is enveloped in a peculiar membranous covering, to which anatomists have given the name of *amnios*. Within this amnios there is a liquid, distinguished by the name of the *liquor of the amnios*, which surrounds the fœtus on every part. This liquid, as might have been expected, is very different in different animals, at least the liquor amnii in women and in cows, which alone have hitherto been analysed, have not the smallest resemblance to each other. These two liquids have been lately analysed by Vauquelin and Buniva, and the result of their analysis has been published in the 33d volume of the *Annales de Chimie*.

303 Liquor of the human amnios.

1. The liquor of the amnios of women is a fluid of a slightly milky colour, a weak but pleasant odour, and a saltish taste. The white colour is owing to a curdy matter suspended in it, for it may be obtained quite transparent by filtration *.

* Ann. de Chim. xxxiii. 270.

Its specific gravity is 1.005. It gives a green colour to the tincture of violets, and yet it reddens very decidedly the tincture of turnsol. These two properties would indicate at once the presence of an acid and of an alkali. It froths considerably when agitated. On the application of heat it becomes opaque, and has then a great resemblance to milk diluted with a large quantity of water. At the same time it exhales the odour of boiled white of egg †.

Liquor of the Amnios.

Acids render it more transparent. Alkalies precipitate an animal matter in small flakes. Alcohol likewise produces a flaky precipitate, which, when collected and dried, becomes transparent, and very like glue. The infusion of nut galls produces a very copious brown coloured precipitate. Nitrat of silver occasions a white precipitate, which is insoluble in nitric acid, and consequently is muriat of silver †.

† Ann. de Chim. xxxiii. 271.

† Ibid.

When slowly evaporated it becomes slightly milky, a transparent pellicle forms on its surface, and it leaves a residuum which does not exceed 0.012 of the whole. By lixiviating this residuum, and evaporating the ley, crystals of muriat and carbonat of soda, may be obtained. The remainder, when incinerated, exhales a fetid and ammoniacal odour, resembling that of burning horn; the ashes consist of a small quantity of carbonat of soda, and of phosphat and carbonat of lime ‡.

‡ Ibid. p. 272.

Thus we see that the liquor of the human amnios is composed of about

98.8 water,
1.2 { albumen, muriat of soda, soda, phosphat of lime, lime,

———

100.0

304 Curdy matter deposited on the fœtus.

While the fœtus is in the uterus, a curdy-like matter is deposited on the surface of its skin, and in particular parts of its body. This matter is often found collected in considerable quantities. It is evidently deposited from the liquor of the amnios; and consequently the knowledge of its peculiar nature must throw considerable light upon the properties and use of that liquor. For an analysis of this substance we are also indebted to Vauquelin and Buniva.

Its colour is white and brilliant; it has a soft feel, and very much resembles newly prepared soap. It is insoluble in water, alcohol, and oils. Pure alkalies dissolve part of it, and form with it a kind of soap. On burning coals it decrepitates like a salt, becomes dry and black, exhales vapours which have the odour of empyreumatic oil, and leaves a residuum which is very difficultly reduced to ashes. When heated in a platinum crucible it decrepitates, lets an oil exude, curls up like horn, and leaves a residuum, consisting chiefly of carbonat of lime ‡.

‡ Ibid. p. 274.

These properties shew that this matter is different from every one of the component parts of the liquor of the amnios, and that it has a great resemblance to the *fat*. It is probable, as Vauquelin and Buniva have conjectured, that it is formed from the albumen of that liquid; which has undergone some unknown changes. It has been long known, that the parts of a fœtus which has lain for some time after it has been deprived of life in the uterus, are sometimes converted into a kind of fatty matter. It is evident that this substance, after it is deposited upon the skin of the fœtus, must preserve it in a great measure from being acted upon by the liquor of the amnios.

305 Liquor of the amnios of the cow.

2. The liquor of the amnios of the cow has a viscidity similar to mucilage of gum arabic, a brownish red colour, an acid and bitter taste, and a peculiar odour, not unlike that of some vegetable extracts. Its specific gravity is 1.028. It reddens the tincture of turnsol, and

Liquor of the Am- and therefore contains an acid. Muriat of barytes causes a very abundant precipitate, which renders it probable that it contains sulphuric acid. Alcohol separates from it a great quantity of a reddish coloured matter §.

§ Ann de Chim xxxiii. p. 275.

306 Its component parts. When this liquid is evaporated, a thick frothy scum gathers on the surface, which is easily separated, and in which some white acid-tasted crystals may be discovered. By continuing the evaporation, the matter becomes thick, and viscid, and has very much the look of honey. Alcohol boiled upon this thick matter, and filtered off, deposites upon cooling brilliant needle-formed crystals nearly an inch in length. These crystals may be obtained in abundance by evaporating the liquor of the amnios to a fourth part of its bulk, and then allowing it to cool. The crystals soon make their appearance. They may be separated and purified by washing them in a small quantity of cold water. These crystals have the properties of an acid §.

§ Ibid p. 276.

If after the separation of this acid the liquor of the amnios be evaporated to the consistence of a syrup, large transparent crystals appear in it, which have all the properties of sulphat of soda. The liquid of the amnios of cows contains a considerable quantity of this salt.

Thus it appears that the liquor of the amnios of cows contains the following ingredients:

1. Water,
2. A peculiar animal matter,
3. A peculiar acid,
4. Sulphat of soda.

307 Nature of the animal matter. The animal matter possesses the following properties: It has a reddish brown colour, and a peculiar taste; it is very soluble in water, but insoluble in alcohol, which has the property of separating it from water. When exposed to a strong heat it swells, exhales first the odour of burning gum, then of empyreumatic oil and of ammonia, and at last the peculiar odour of prussic acid becomes very conspicuous. It differs from gelatine in the viscidity which it communicates to water, in not forming a jelly when concentrated, and in not being precipitated by tan. It must be therefore ranked among the very undefined and inaccurate class of *animal mucilages*.

When burnt, it leaves a very large coal, which is readily incinerated, and leaves a little white ashes, composed of phosphat of magnesia, and a very small proportion of phosphat of lime ||.

|| Ibid. p. 278.

308 Amniotic acid. The acid substance is of a white and brilliant colour; its taste has a very slight degree of sourness; it reddens the tincture of turnsol; it is scarcely soluble in cold water, but very readily in hot water, from which it separates in long needles as the solution cools. It is soluble also in alcohol, especially when assisted by heat. It combines readily with pure alkalies, and forms a substance which is very soluble in water. The other acids decompose this compound; and the acid of the liquor of the amnios is precipitated in a white crystalline powder. This acid does not decompose the alkaline carbonats at the temperature of the atmosphere, but it does so when assisted by heat. It does not alter solutions of silver, lead, or mercury, in nitric acid. When exposed to a strong heat, it frothes and exhales an odour of ammonia and of prussic acid. The properties are sufficient to shew that it is different from every other acid. Vauquelin and Boniva have given it the name of *amniotic acid*. It approaches nearest to the saccholactic and the *uric* acids; but the sachlactic acid does not furnish ammonia by distillation like the amniotic. The uric acid is not so soluble in hot water as the amniotic, it does not crystallize in white brilliant needles, and it is insoluble in boiling alcohol; in both which respects it differs completely from amniotic acid *.

Urine.

* Ann. de Chim. xxxiii. p. 279.

Sect. XVI. Of Urine.

309 Urine. No animal substance has attracted more attention than urine, both on account of its supposed connection with various diseases, and on account of the very singular products which have been obtained from it. Mr Boyle, and the other chemists who were his contemporaries, were induced to attend particularly to this liquid, by the discovery of a method of obtaining phosphorus from it. Boerhaave, Haller, Haupt, Margraf, Pott, Rouelle, Proust, and Klaproth, successively, improved the method of obtaining the phosphoric salts from urine, or added something to our knowledge of the component parts of these salts. Scheele added greatly to our knowledge of urine by detecting several new substances in it which had not been suspected. Cruickshank has given us a very valuable paper on urine in the second edition of *Rollo's Diabetes*; and Fourcroy and Vauquelin have lately published the most complete analysis of it which has hitherto appeared.

Fresh urine is a liquid of a peculiar aromatic odour, an orange colour, of greater or less intensity, and an acid saline taste.

Its specific gravity varies from 1.005 to 1.033 *.

1. It reddens paper stained with turnsol and with the juice of radishes, and therefore contains an acid.

2. If a solution of ammonia be poured into fresh urine, a white powder precipitates, which has the properties of phosphat of lime. The presence of this substance in urine was first discovered by Scheele †. If lime water be poured into urine, phosphat of lime precipitates in greater abundance than when ammonia is used; consequently the acid which urine contains is the phosphoric. Thus we see that the phosphat of lime is kept dissolved in urine by an excess of acid. This also was first discovered by Scheele ‡. This substance is most abundant in the urine of the sick. Berthollet has observed, that the urine of gouty people is less acid than that of people in perfect health. The average quantity of phosphat of lime in healthy urine is, as Cruickshank has ascertained, about $\frac{1}{300}$ of the weight of the urine §.

* ... 40.

Contains phosphat of lime.

† Scheele, i. 208.

‡ Ibid.

§ Phil. Mag. ii. 241.

311 Phosphat of magnesia. 3. If the phosphat of lime precipitated from urine be examined, a little magnesia will be found mixed with it. Fourcroy and Vauquelin have ascertained that this is owing to a little phosphat of magnesia which urine contains, and which is decomposed by the alkali or lime employed to precipitate the phosphat of lime ¶.

¶ Ann. de Chim. xxxi. 66.

312 Uric acid. 4. When fresh urine cools, it often lets fall a brick coloured precipitate, which Scheele first ascertained to be crystals of uric acid. All urine contains this acid, even when no sensible precipitate appears when it cools. For if a sufficient quantity of clear and fresh urine be evaporated to $\frac{1}{128}$ of its weight, a subtle powder precipitates to the bottom, and attaches itself in part very firmly to the vessel. This part may be dissolved in pure alkali, and precipitated again by acetous acid. It exhibits all the properties of uric acid *. The quantity of uric acid in urine is very various. During intermittent

* Scheele, i. 207.

Urine.

termittent fevers it is depofited very copioufly, and has been long known to phyficians under the name of *lateritious fediment*. This fediment always makes its appearance at the crifis of fevers. In gouty people, the fame fediment appears in equal abundance towards the end of a paroxyfm of the difeafe (P). And if this fediment fuddenly difappears after it has begun to be depofited, a frefh attack may be expected *.

* *Cruikfhank, Phil. Mag.* ii. 249.

5. If frefh urine be evaporated to the confiftence of a fyrup, and muriatic acid be then poured into it, a precipitate appears which poffeffes the properties of

313 Benzoic acid,

benzoic acid. Scheele firft difcovered the prefence of benzoic acid in urine. He evaporated it to drynefs, feparated the faline part, and applied heat to the refiduum. The benzoic acid was fublimed, and found cryftallized in the receiver. The method which we have given is much eafier; it was firft propofed by Fourcroy and Vanquelin †. By it very confiderable quantities of benzoic acid may be obtained from the urine of horfes and cows, where it is much more abundant than in human urine. In human urine it varies from $\frac{1}{1400}$ to $\frac{1}{1800}$ of the whole §.

† *Ann. de Chim.* xxxi. 62.

§ *Ibid.* p. 63.

314 Albumen and gelatine,

6. When an infufion of tan is dropt into urine, a white precipitate appears, having the properties of the combination of tan and albumen, or gelatine. Urine, therefore, contains albumen and gelatine. Thefe fubftances had been fufpected to be in urine, but their prefence was firft demonftrated by Seguin, who difcovered the above method of detecting them. Their quantity in healthy urine is very fmall. Cruikfhank found that the precipitate afforded by tan in healthy urine amounted to $\frac{1}{240}$th part of the weight of the urine ‡. It is to thefe fubftances that the appearance of the *cloud*, as it is called, or the mucilaginous matter, which is fometimes depofited as the urine cools, is owing. It is probable that healthy urine contains only gelatine and not albumen, though the quantity is too fmall to admit of accurate examination; but in many difeafes the quantity of thefe matters is very much increafed. The urine of dropfical people often contains fo much albumen, that it coagulates not only on the addition of acids, but even on the application of heat §. In all cafes of impaired digeftion, the albuminous and gelatinous part of urine is much increafed. This forms one of the moft confpicuous and important diftinctions between the urine of thofe who enjoy good and bad health ||.

‡ *Phil. Mag.* ii. 243.

|| *Fourcroy and Vauquelin, Ann. Chim.* xi. 81

315 Urea,

7. If urine be evaporated by a flow fire to the confiftence of a thick fyrup, it affumes a deep brown colour, and exhales a fetid ammoniacal odour. When allowed to cool, it concretes into a mafs of cryftals, compofed of all the component parts of urine. If four times its weight of alcohol be poured upon this mafs, at intervals, and a flight heat be applied, the greateft part of it is diffolved. The alcohol, which has acquired a brown colour, is to be decanted off, and diftilled in a crucible in a fand heat, till the mixture has boiled for fome time, and acquired the confiftence of a fyrup. By this time the whole of the alcohol has paffed off, and the matter, on cooling, cryftallizes in quadrangular plates which interfect each other. This fubftance is *urea*, which compofes $\frac{4}{5}$ of the urine, provided the watery part be excluded. To this fubftance the tafte, fmell, and colour of urine are owing. It is a fubftance which characterizes urine, and conftitutes it what it is, and to which the greater part of the very fingular phenomena of urine are to be afcribed.

The colour of urine depends upon the urea; the greater the quantity, the deeper is the colour. It may be detected by evaporating urine to the confiftence of a fyrup, and pouring into it concentrated nitric acid. Immediately a great number of white fhining cryftals appear in the form of plates, very much refembling cryftallized boracic acid. Thefe cryftals are urea combined with nitric acid.

The quantity of urea varies exceedingly in different urines. In the urine voided foon after a meal, very little of it is to be found, and fcarcely any at all in that which hyfterical patients void during a paroxyfm.

8. If urine be flowly evaporated to the confiftence of 316 Muriat of foda,
a fyrup, a number of cryftals make their appearance in it. Two of thefe are remarkable by their form: one of them confifts of fmall regular octahedrons; which, when examined, are found to poffefs the properties of muriat of foda. Urine, therefore, contains muriat of foda. It is well known that muriat of foda cryftallizes in cubes; the fingular modification of its form in urine is owing to the action of urea. It has been long known that urine faturated with muriat of foda depofites that falt in regular octahedrons.

9. Another of the falts which appear during the evaporation of urine has the form of regular cubes. This 317 Muriat of ammonia,
falt has the properties of muriat of ammonia. Now the ufual form of the cryftals of muriat of ammonia is the octahedron. The change of its form in urine is produced alfo by urea.

10. The faline refiduum which remains after the feparation of urea from cryftallized urine by means of alcohol, has been long known under the names of fufible 318 Phofphat of ammonia and of foda
falt of urine and microcofmic falt. Various methods of obtaining it have been given by chemifts from Boerhaave, who firft publifhed a procefs, to Rouelle and Chaulnes, who gave the method juft mentioned. If this faline mafs be diffolved in a fufficient quantity of hot water, and allowed to cryftallize fpontaneoufly in a clofe veffel, two fets of cryftals are gradually depofited. The lowermoft fet has the figure of flat rhomboidal prifms; the uppermoft, on the contrary, has the form of rectangular tables. Thefe two may be eafily feparated by expofing them for fome time to a dry atmofphere. The rectangular tables efflorefce and fall to powder, but the rhomboidal prifms remain unaltered.

When thefe falts are examined, they are found to have the properties of phofphats. The rhomboidal prifms confift of phofphat of ammonia united to a little phofphat of foda; the rectangular tables, on the contrary,

(P) The concretions which fometimes make their appearance in gouty joints have been found to confift chiefly of uric acid. This fingular coincidence deferves the attention of phyfiologifts: it cannot fail, fooner or later, to throw light, not only upon gout, but upon fome of the animal functions.

trary, are phosphat of soda united to a small quantity of phosphat of ammonia. Urine, then, contains phosphat of soda and phosphat of ammonia.

Thus we have found that urine contains the twelve following substances:

Water,	7. Gelatine and albumen,
Phosphoric acid,	8. Urea,
Phosphat of lime,	9. Muriat of soda,
Phosphat of magnesia,	10. Muriat of ammonia,
Uric acid,	11. Phosphat of soda,
Benzoic acid,	12. Phosphat of ammonia.

319 Sometimes other salts.

These are the only substances which are constantly found in healthy urine *; but it contains also occasionally other substances. Very often muriat of potass may be distinguished among the crystals which form during its evaporation. The presence of this salt may always be detected by dropping cautiously some tartarous acid into urine. If it contains muriat of potass, there will precipitate a little tartar, which may easily be recognised by its properties *.

* Fourcroy and Vauquelin, Ann de Chim xxxi. 69.

* Cruikshank, Phil. Mag. ii, 441.

Urine sometimes also contains sulphat of soda, and even sulphat of lime. The presence of these salts may be ascertained by pouring into urine a solution of muriat of barytes, a copious white precipitate appears, consisting of the barytes combined with phosphoric acid, and with sulphuric acid, if any be present. This precipitate must be treated with a sufficient quantity of muriatic acid. The phosphat of barytes is dissolved, but the sulphat of barytes remains unaltered †.

† Fourcroy, Ann. de Chim vii. 183.

320 Putrefaction of urine.

No substance putrefies sooner, or exhales a more detestable odour during its spontaneous decomposition, than urine; but there is a very great difference in this respect in different urines. In some, putrefaction takes place almost instantaneously as soon as it is voided; in others, scarcely any change appears for a number of days. Fourcroy and Vauquelin have ascertained that this difference depends on the quantity of gelatine and albumen which urine contains. When there is very little of these substances present, urine remains long unchanged; on the contrary, the greater the quantity of gelatine or albumen, the sooner does putrefaction commence. The putrefaction of urine, therefore, is, in some degree, the test of the health of the person who has voided it; for a superabundance of gelatine in urine always indicates some defect in the power of digestion *.

* Ann de Chim. xxxi. 61.

The rapid putrefaction of urine, then, is owing to the action of gelatine on urea. We have seen already the facility with which that singular substance is decomposed, and that the new products into which it is changed are, ammonia, carbonic acid, and acetous acid. Accordingly, the putrefaction of urine is announced by an ammoniacal smell. Mucilaginous flakes are deposited, consisting of part of the gelatinous matter. The phosphoric acid is saturated with ammonia, and the phosphat of lime, in consequence, is precipitated. Ammonia combines with the phosphat of magnesia, forms with it a triple salt, which crystallizes upon the sides of the vessel in the form of white crystals, composed of six-sided prisms, terminated by six sided pyramids. The uric and benzoic acids are saturated with ammonia; the acetous acid, and the carbonic acid, which are the products of the decomposition of the urea, are also saturated with ammonia, and notwithstanding the quantity which exhales, the production of this substance is so abundant, that there is a quantity of unsaturated alkali in the liquid. Putrefied urine, therefore, contains chiefly the following substances, most of which are the products of putrefaction:

Ammonia,
Carbonat of ammonia,
Phosphat of ammonia,
Phosphat of magnesia and ammonia,
Urat of ammonia,
Acetite of ammonia,
Benzoat of ammonia,
Muriat of soda,
Muriat of ammonia;

Besides the precipitated gelatine and phosphat of lime *.

* Ann. de Chim xxxi. 70.

The distillation of urine produces almost the same changes; for the heat of boiling water is sufficient to decompose urea, and to convert it into ammonia, carbonic and acetous acids. Accordingly, when urine is distilled, there comes over water, containing ammonia dissolved in it, and carbonat of ammonia in crystals. The acids contained in urine are saturated with ammonia, and the gelatine and phosphat of lime precipitate †.

† Ibid, 55.

Such are the properties of the human urine. The urine of other animals has not hitherto been examined with equal care; but it is certain that it differs very considerably from that of men. The urine of cows and horses, and of all ruminating animals, for instance, contains carbonat of lime, without any mixture of phosphat of lime ‡. It contains also a much greater proportion of benzoic acid than that of man.

‡ Vauquelin, ibid. xxix. 4.

SECT. XVII. *Of the URINARY CALCULUS.*

IT is well known that concretions not unfrequently form in the bladder, or the other urinary organs, and occasion one of the most dismal diseases to which the human species is liable.

321 Urinary calculi.

These concretions were distinguished by the name of *calculi*, from a supposition that they are of a stony nature. They have long attracted the attention of physicians. Chemistry had no sooner made its way into medicine than it began to exercise its ingenuity upon the urinary calculus; and various theories were given of their nature and origin. According to Paracelsus, who gave them the ridiculous name of *duelech*, urinary calculi were intermediate between tartar and stone, and composed of an *animal resin*. Van Helmont pronounced them anomalous coagulations, the offspring of the salts of urine, and of a volatile earthy spirit, produced at once, and destitute of any viscid matter §. Boyle extracted from them, by distillation, oil, and a great quantity of volatile salt. Boerhaave supposed them compounds of oil and volatile salts. Hales extracted from them a prodigious quantity of air. He gave them the name of *animal tartar*, pointed out several circumstances in which they resemble common tartar, and made many experiments to find a solvent of them *. Drs Whytt and Alston pointed out alkalies as solvents of calculi. It was an attempt to discover a more perfect solvent that induced Dr Black to make those experiments which terminated in the discovery of the nature of the alkaline carbonats.

§ De Lithiasi, c. 3.

* Veget. Stat. ii. 189.

322 Analysed by Scheele.

Such was the state of the chemical analysis of calculus, when, in 1776, Scheele published a dissertation on the subject in the *Stockholm Transactions*; which was succeeded by some remarks of Mr Be [illegible]a. These

illustrious

Urinary Calculi.

illuſtrious chemiſts completely removed the uncertainty which had hitherto hung over the ſubject, and aſcertained the nature of the calculi which they examined. Since that time conſiderable additional light has been thrown upon the nature of theſe concretions by the labours of Auſtin, Pearſon, and, above all, of Fourcroy and Vauquelin, who have lately analyſed above 300 calculi, and aſcertained the preſence of ſeveral new ſubſtances which had not been ſuſpected. The ſubſtances hitherto diſcovered in urinary calculi are the following:

323 Their component parts.

1. Uric acid,
2. Urat of ammonia,
3. Phoſphat of lime (q),
4. Phoſphat of magneſia-and-ammonia,
5. Oxalat of lime,
6. Silica,
7. An animal matter.

324 Uric acid.

1. The greater number of calculi conſiſt of uric acid. All thoſe analyſed by Scheele were compoſed of it entirely. Of 300 calculi analyſed by Dr Pearſon, ſcarcely one was found which did not contain a conſiderable quantity of it, and the greater number manifeſtly were formed chiefly of it. Fourcroy and Vauquelin found it alſo in the greater number of the 300 calculi which they analyſed.

The preſence of this acid may eaſily be aſcertained by the following properties: A ſolution of potaſs or ſoda diſſolves it readily, and it is precipitated by the weakeſt acids. The precipitate is ſoluble in nitric acid, the ſolution is of a pink colour, and tinges the ſkin red *.

* Fourcroy, Ann. de Chim. xxxii. 216.

325 Urat of ammonia.

2. Urat of ammonia is eaſily detected by its rapid ſolubility in fixed alkaline leys, and the odour of ammonia which is perceived during the ſolution. It is not ſo often preſent in urinary calculi as the laſt mentioned ſubſtance. No calculus has hitherto been found compoſed of it alone, except the very ſmall polygonal calculi, ſeveral of which ſometimes exiſt in the bladder together.

It is moſt uſually in thin layers, alternating with ſome other ſubſtances, very eaſily reduced to powder, and of the colour of ground coffee †.

† Ibid. 218.

316 Phoſphat of lime.

3. Phoſphat of lime is white, without luſtre, fiery, friable, ſtains the hands, paper, and cloth. It has very much the appearance of chalk, breaks under the forceps, is inſipid, and inſoluble in water. It is ſoluble in nitric, muriatic, and acetous acids, and is again precipitated by ammonia, fixed alkalies, and oxalic acid.

It is never alone in calculi. It is intimately mixed with a gelatinous matter, which remains under the form of a membrane when the earthy part is diſſolved by very diluted acids ‡.

‡ Ibid.

317 Phoſphat of magneſia-and-ammonia.

4. Phoſphat of magneſia-and-ammonia occurs in white, ſemitranſparent, lameller layers; ſometimes it is cryſtallized on the ſurface of the calculi in priſms, or what are called *dog-tooth* cryſtals. It has a weak ſweetiſh taſte, it is ſomewhat ſoluble in water, and very ſoluble in acids, though greatly diluted. Fixed alkalies decompoſe it.

It never forms entire calculi. Sometimes it is mixed with phoſphat of lime, and ſometimes layers of it cover uric acid or oxalat of lime. It is mixed with the ſame gelatinous matter as phoſphat of lime ‡.

‡ Fourcroy, Ann. de Chim. xxxii. 219.

318 Oxalat of lime.

5. Oxalat of lime is found in certain calculi, which, from the inequality of their ſurface, have got the name of *moriform* or *mulberry ſhaped* calculi. It is never alone, but combined with a peculiar animal matter, and forming with it a very hard calculus, of a grey colour, difficult to ſaw aſunder, admitting a poliſh like ivory, exhaling, when ſawed, an odour like that of ſemen. Inſoluble and indecompoſible by alkalies; ſoluble in very diluted nitric acid, but ſlowly, and with difficulty. It may be decompoſed by the carbonats of potaſs and ſoda. When burnt, it leaves behind a quantity of pure lime, which may be eaſily recogniſed by its properties *.

* Ibid. 220.

329 Silica.

6. Silica has only been found in two inſtances by Fourcroy and Vauquelin, though they analyſed 300 calculi. No other chemiſt has obſerved it. It muſt therefore be conſidered as a very uncommon ingredient of theſe concretions. In the two inſtances in which it occurred, it was mixed with uric acid and the two phoſphats above mentioned †.

† Ibid. 221.

330 Animal matters.

7. *Animal matter* appears to compoſe the cement which binds the different particles of the calculus together, and in all probability it is the cauſe which influences its formation. It is different in different calculi. Sometimes it has the appearance of gelatine or albumen, at other times it reſembles urea. It deſerves a more accurate inveſtigation ‡.

‡ Ibid.

No general deſcription of the different calculi has hitherto appeared; but Fourcroy and Vauquelin are at preſent occupied with that ſubject. They propoſe to claſſify them according to their compoſition; to point out their different ſpecies and varieties; to give a method of detecting them by their appearance; to analyſe the animal matter by which they are cemented; and to apply all the preſent chemical knowledge of the ſubject in the inveſtigation of the cauſe, the ſymptoms, and the cure, of that dreadful diſeaſe which the urinary calculi produce. As their labour is already very far advanced, it would be unneceſſary for us to attempt any claſſification of calculi. Indeed every attempt of that kind, by any perſon who has not had an opportunity of analyſing a very great number of calculi, muſt be ſo exceedingly imperfect as ſcarcely to be of any uſe.

We ſhall ſatisfy ourſelves with the following remarks, deduced almoſt entirely from the obſervations which theſe celebrated chemiſts have already publiſhed.

331 Method of diſſolving the calculi.

Many calculi conſiſt entirely, or almoſt entirely, of uric acid. The animal matter, which ſerves as a cement to theſe calculi, appears to be urea. Calculi of this kind may be diſſolved by injecting into the bladder ſolutions of pure potaſs or ſoda, ſo much diluted as not to act upon the bladder itſelf. The gritty ſubſtance, which many perſons threatened with the ſtone diſcharge along with their urine, which has been called *gravel*, conſiſts almoſt conſtantly of uric acid. It may therefore ſerve as an indication that the ſubſequent ſtone, if any ſuch form, is probably compoſed of uric acid.

The two phoſphats, mixed together, ſometimes compoſe calculi. Theſe calculi are very brittle, and generally

(q) Brugnatelli found alſo phoſphat of lime, with exceſs of acid, in calculi. See *Ann. de Chim.* xxxii. 183.

Urinary Calculus.

rally break in pieces during the extraction. Such calculi may be dissolved by injecting into the bladder muriatic acid, so much diluted as scarcely to have any taste of acid.

The phosphats never form the nucleus of a calculus. They have never been found covered with a layer of uric acid, but they often cover that acid. Hence it would seem that the existence of any extraneous matter in the bladder disposes these phosphats to crystallize. When extraneous bodies are accidentally introduced into the bladder, and allowed to lodge there, they are constantly covered with a coat of phosphat of ammonia and magnesia, or of the two phosphats mixed.

As the phosphat of ammonia and magnesia is not an ingredient of fresh urine, but formed during its putrefaction, when it exists in calculi, it would seem to indicate a commencement of putrefaction during the time that the urine lodges in the bladder. But putrefaction does not take place speedily in urine, unless where there is an excess of albumen and gelatine; consequently we have reason to suppose, that these substances are morbidly abundant in the urine of those patients who are afflicted with calculi consisting of the phosphats: hence also we may conclude, that their digestion is imperfect. It will no doubt be objected, that dropsical people are not peculiarly subject to calculi; but their urine is only morbidly albuminous when the disease is beginning to disappear, and then there seems to be a deficiency of urea; at least their urine has not been observed to putrefy with uncommon rapidity. Besides, there seems to be some animal matter present, which serves as a cement to the phosphat in all cases where calculi form.

Urat of ammonia is only found alone in the very small polygonous calculi which exist, several together, in the bladder. In other cases it is mixed with uric acid. It sometimes alternates with uric acid or with the phosphats. It is dissolved by the same substance that acts as a solvent of uric acid.

Oxalat of lime often forms the nucleus of calculi composed of layers of uric acid or of the phosphats. It forms those irregular calculi which are called *moriform*. These calculi are the hardest and the most difficult of solution. A very much diluted nitric acid dissolves them but very slowly. As oxalic acid does not exist in urine, some morbid change must take place in the urine when such calculi are deposited. Brugnatelli's discovery of the instantaneous conversion of uric acid into oxalic acid by oxy-muriatic acid, which has been confirmed by the experiments of Fourcroy and Vauquelin, throws considerable light upon the formation of oxalic acid in urine, by shewing us that uric acid is probably the basis of it; but in what manner the change is actually produced, it is not so easy to say.

The calculi found in the bladder of other animals have not been examined with the same care. Some of them, however, have been subjected to an accurate analysis. No uric acid has ever been found in any of them.

132 Calculi of inferior animals.

Fourcroy found a calculus extracted from the kidney of a horse composed of three parts of carbonat of lime, and one part phosphat of lime *. Dr Pearson examined a urinary calculus of a horse; it was composed of phosphat of lime and phosphat of ammonia. Brugnatelli found a calculus extracted from the bladder of a sow, which was exceedingly hard, composed of pure carbonat of lime, inclosing a soft nucleus of a fœtid and urinous odour †. Bartholdi examined another calculus of a pig, the specific gravity of which was 1.9000. It consisted of phosphat of lime ‡. Dr Pearson found a calculus taken from the bladder of a dog composed of phosphat of lime, phosphat of ammonia, and an animal matter. He found the urinary calculus of a rabbit, of the specific gravity 2, composed of carbonat of lime and some animal matter ||.

We have now given an account of all those secretions which have been attentively examined by chemists. The remainder have been hitherto neglected; partly owing to the difficulty of procuring them, and partly on account of the multiplicity of other objects which occupied the attention of chemical philosophers (x). It remains for us now to examine by what processes these different secretions are formed, how the constant waste of living bodies is repaired, and how the organs themselves are nourished and preserved. This shall form the subject of the following chapter.

Chap. III. Of the Functions of Animals.

The intention of the two last chapters was to exhibit a view of the different substances which enter into the composition of animals, as far as the present limited state of our knowledge puts it in our power. But were our enquiries concerning animals confined to the mere ingredients of which their bodies are composed, even supposing the analysis as complete as possible, our knowledge of the nature and properties of animals would be imperfect indeed.

How are these substances arranged? How are they produced?

(x) The chief of these secretions are the following:

1. Cerumen, or ear-wax, is at first nearly liquid, and of a whitish colour. It gradually acquires consistence. Its taste is very bitter. Said to be insoluble in alcohol; but soluble in hot water. Does not become rancid by keeping.
2. The humours of the eye.
3. The milky liquor, secreted by the thyroid gland.
4. Mucus of the lungs, intestinal canal, &c.
5. Smegma of the areola of the breasts, glans penis, vagina, subcutaneous glands, &c.
6. Marrow.

Functions of Animals produced? What purposes do they serve? What are the distinguishing properties of animals, and the laws by which they are regulated?

333 Animals resemble vegetables. Animals resemble vegetables in the complexness of their structure. Like them, they are machines nicely adapted for particular purposes, constituting one whole, and continually performing an infinite number of the most delicate processes. But neither an account of the structure of animals, nor of the properties which distinguish them from other beings, will be expected here. These have been already treated of sufficiently in the articles ANATOMY and PHYSIOLOGY (*Encycl.*), to which we beg leave to refer the reader. We mean only, in the present chapter, to take a view of those processes which are concerned in the *production* of animal substances, which alone properly belong to chemistry. The other functions are regulated by laws of a very different nature, which have no resemblance or analogy to the laws of chemistry or mechanics.

334 Require food. 1. Every body knows that animals require food, and that they die sooner or later if food be withheld from them. There is indeed a very great difference in different animals, with regard to the quantity of food which they require, and the time which they can pass without it. In general, this difference depends upon the activity of the animal. Those which are most active require most, and those which move least require least food.

The cause of this is also well known; the bodies of animals do not remain stationary, they are constantly wasting; and the waste is generally proportional to the activity of the animal. It is evident, then, that the body must receive, from time to time, new supplies, in place of what has been carried off. Hence the use of food, which answers this purpose.

335 Its nature. 2. We are much better acquainted with the food of animals than of vegetables. It consists of almost all the animal and vegetable substances which have been treated of in the former part of this article; for there are but few of them which some animal or other does not use as food. Man uses as food chiefly the muscles of animals, the seeds of certain grasses, and a variety of vegetable fruits. Almost all the inferior animals have particular substances on which they feed exclusively. Some of them feed on animals, others on vegetables. Man has a greater range; he can feed on a very great number of substances. To enumerate these substances would be useless; as we are not able to point out with accuracy what it is which renders one substance more nourishing than another.

Many substances do not serve as nourishment at all; and not a few, instead of nourishing, destroy life. These last are called *poisons*. Some poisons act chemically, by decomposing the animal body. The action of others is not so well understood.

336 Converted into chyme. 3. The food is introduced into the body by the mouth, and almost all animals reduce it to a kind of pulpy consistence. In man and many other animals this is done in the mouth by means of teeth, and the saliva with which it is there mixed; but many other animals grind their food in a different manner. See PHYSIOLOGY, (*Encycl.*) After the food has been thus ground, it is introduced into the stomach, where it is subjected to new changes. The stomach is a strong soft bag, of different forms in different animals: in man it has some resemblance to the bag of a *bag-pipe*. In this organ the food is converted into a soft pap, which has no resemblance to the food when first introduced. This pap has been called *chyme*. Functions of Animals.

4. Since chyme possesses new properties, it is evident that the food has undergone some changes in the stomach, and that the ingredients of which it was composed have entered into new combinations. Now, in what manner have these changes been produced?

At first they were ascribed to the mechanical action of the stomach. The food, it was said, was still farther triturated in that organ; and being long agitated backwards and forwards in it, was at last reduced to a pulp. But this opinion, upon examination, was found not to be true. The experiments of Stevens, Reaumur, and Spallanzani, demonstrated, that the formation of chyme is not owing to trituration; for on inclosing different kinds of food in metallic tubes and balls full of holes, in such a manner as to screen them from the mechanical action of the stomach, they found, that these substances, after having remained a sufficient time in the stomach, were converted into chyme, just as if they had not been inclosed in such tubes. Indeed, the opinion was untenable, even independent of these decisive experiments, the moment it was perceived that chyme differed entirely from the food which had been taken; that is to say, that if the same food were triturated mechanically out of the body, and reduced to pap of precisely the same consistence with chyme, it would not possess the same properties with chyme; for whenever this fact was known, it could not but be evident that the food had undergone changes in its composition.

The change of food into chyme, therefore, was ascribed by many to *fermentation*. This opinion is indeed very ancient, and it has had many zealous supporters among the moderns. When the word *fermentation* was applied to the change produced on the food in the stomach, the nature of the process called fermentation was altogether unknown. The appearances, indeed, which take place during that process, had been described, and the progress and the result of it were known. Chemists had even divided fermentations into different classes; but no attempt had been made to explain the cause of fermentation, or to trace the changes which take place during its continuance. All that could be meant, then, by saying that the conversion of food into chyme in the stomach was owing to fermentation, was merely, that the unknown cause which acted during the conversion of vegetable substances into wine or acid, or during their putrefaction, acted also during the conversion of the food into chyme, and that the result in both cases was precisely the same. Accordingly, the advocates for this opinion attempted to prove, that air was constantly generated in the stomach, and that an acid was constantly produced: for it was the vinous and acetous fermentations which were assigned by the greater number of physiologists as the cause of the formation of chyme. Some indeed attempted to prove, that it was produced by the putrefactive fermentation; but their number was inconsiderable, compared with those who adopted the other opinion.

Our ideas respecting fermentation are now somewhat more precise. It signifies a slow decomposition, which takes place when certain animal or vegetable substances are mixed together at a given temperature; and the

consequent production of particular compoun[illegible] If therefore the conversion of the food into chyme be owing to fermentation, it is evident that i[illegible]tally independent of the stomach any farther th[illegible]s it supplie[illegible] temperature; and that the food would [illegible] converted into chyme exactly in the same manner, [illegible] were reduced to the same consistence, and placed in the same temperature out of the body. But this is by no means the case; substances are reduced to the state of chyme in a short time in the stomach, which would remain unaltered for weeks in the same temperature out of the body. This is the case with bones; which the experiments of Stevens and Spallanzani have shewn to be soon digested in the stomach of the dog. Farther, if the conversion of food into chyme were owing to fermentation, it ought to go on equally well in the stomach and œsophagus. Now, it was observed long ago by Ray and Boyle, that when voracious fish had swallowed animals too large to be contained in the stomach, that part only which was in the stomach was converted into chyme, while what was in the œsophagus remained entire; and this has been fully confirmed by subsequent observations.

Still farther, if the conversion were owing to fermentation, it ought always to take place equally well, provided the temperature be the same, whether the stomach be in a healthy state or not. But it is well known, that this is not the case. The formation of chyme depends very much on the state of the stomach. When that organ is diseased, digestion is constantly ill performed. In these cases, indeed, fermentation sometimes appears, and produces flatulence, acid eructations, &c. which are the well-known symptoms of indigestion. These facts have been long known; they are totally incompatible with the supposition, that the formation of chyme is owing to fermentation. Accordingly that opinion has been for some time abandoned, by all those at least who have taken the trouble to examine the subject.

337 By the action of the gastric juice.

The formation of chyme, then, is owing to the stomach; and it has been concluded, from the experiments of Stevens, Reaumur, Spallanzani, Scopoli, Brugnatelli, Carimini, &c. that its formation is brought about by the action of a particular liquid secreted by the stomach, and for that reason called *gastric juice*.

That it is owing to the action of a liquid, is evident; because if pieces of food be inclosed in close tubes, they pass through the stomach without any farther alteration than would have taken place at the same temperature out of the body: but if the tubes be perforated with small holes, the food is converted into chyme.

This liquid does not act indiscriminately upon all substances: For if grains of corn be put into a perforated tube, and a granivorous bird be made to swallow it, the corn will remain the usual time in the stomach without alteration; whereas if the husk of the grain be previously taken off, the whole of it will be converted into chyme. It is well known, too, that many substances pass unaltered through the intestines of animals, and consequently are not acted upon by the gastric juice. This is the case frequently with grains of oats when they have been swallowed by horses entire with their husks on. This is the case also with the seeds of apples, &c. when swallowed entire by man; yet these very substances, if they have been previously ground sufficiently by the teeth, are digested. It appears, therefore, that it is chiefly the husk or outside of these substances which resists the action of the gastric juice. We see also, that trituration greatly facilitates the conversion of food into chyme.

338 Nature of gastric juice.

The gastric juice is not the same in all animals; for many animals cannot digest the food on which others live. The *conium maculatum* (hemlock), for instance, is a poison to man instead of food, yet the goat often feeds upon it. Many animals, as sheep, live wholly upon vegetables; and if they are made to feed on animals, their stomachs will not digest them: others, again, as the eagle, feed wholly on animal substances, and cannot digest vegetables.

The gastric juice does not continue always of the same nature, even in the same animal: it changes gradually, according to circumstances. Graminivorous animals may be brought to live on animal food; and after they have been accustomed to this for some time, their stomachs become incapable of digesting vegetables. On the other hand, those animals which naturally digest nothing but animal food may be brought to digest vegetables.

What is the nature of the gastric juice, which possesses these singular properties? It is evidently different in different animals; but it is a very difficult task, if not an impossible one, to obtain it in a state of purity. Various attempts have indeed been made by very ingenious philosophers to procure it; but their analysis of it is sufficient to shew us, that they have never obtained it in a state of purity.

The methods which have been used to procure gastric juice are, *first*, to kill the animal whose gastric juice is to be examined after it has fasted for some time. By this method, Spallanzani collected 37 spoonfuls from the two first stomachs of a sheep. It was of a green colour, undoubtedly owing to the grass which the animal had eaten. He found also half a spoonful in the stomach of some young crows which he killed before they had left their nest.

Small tubes of metal, pierced with holes, and containing a dry sponge, have been swallowed by animals; and when vomited up, the liquid imbibed by the sponge is squeezed out. By this method, Spallanzani collected 481 grains of gastric juice from the stomachs of five crows.

A *third* method consists in exciting vomiting in the morning, when the stomach is without food. Spallanzani tried this method twice upon himself, and collected one of the times 1 oz. 32 gr. of liquid; but the pain was so great, that he did not think proper to try the experiment a third time. Mr Gosse, however, who could excite vomiting whenever he thought proper by swallowing air, has employed that method to collect gastric juice.

Spallanzani has observed, that eagles throw up every morning a quantity of liquid, which he considers as gastric juice; and he has availed himself of this to collect it in considerable quantities.

It is almost unnecessary to remark how imperfect these different methods are, and how far every conclusion drawn from the examination of such juices must deviate from the truth. It is impossible that the gastric juice, obtained by any one of these processes, can be pure; because in the stomach it must be constantly mixed

mixed with larg[e] quantities of faliva, mucus, bile, food, &c. It may be queftioned, indeed, whether any gaftric juice at all can be obtained by thefe methods: for as the intention of the gaftric juice is to convert the f[ood] into chyme, in all probability it is only fecreted, or at leaft thrown into the ftomach when food is prefent.

We need not be furprifed, then, at the contradictory accounts concerning its nature, given us by thofe philofophers who have attempted to examine it; as thefe relate not fo much to the gaftric juice, as to the different fubftances found in the ftomach. The idea that the gaftric juice can be obtained by vomiting, or that it is thrown up fpontaneoufly by fome animals, is, to fay the leaft of it, very far from being probable.

According to Brugnatelli, the gaftric juice of carnivorous animals, as hawks, kites, &c. has an acid and refinous odour, is very bitter, and not at all watery; and is compofed of an uncombined acid, a refin, an animal fubftance, and a fmall quantity of muriat of foda *. The gaftric juice of herbivorous animals, on the contrary, as goats, fheep, &c. is very watery, a little muddy, has a bitter faltifh tafte, and contains ammonia, an animal extract, and a pretty large quantity of muriat of foda †. Mr Carminati found the fame ingredients; but he fuppofes that the ammonia had been formed by the putrefaction of a part of their food, and that in reality the gaftric juice of thefe animals is of an acid nature ‡.

The accounts which have been given of the gaftric juice of man are fo various, that it is not worth while to tranfcribe them. Sometimes it has been found of an acid nature, at other times not. The experiments of Spallanzani are fufficient to fhew, that this acidity is not owing to the gaftric juice, but to the food. He never found any acidity in the gaftric juice of birds of prey, nor of ferpents, frogs, and fifhes. Crows gave an acidulous gaftric juice only when fed on grain; and he found that the fame [illegible] holds with refpect to dogs, [illegible] domeftic fowls. Carnivorous birds threw up pieces of fhells and coral without alteration; but thefe fubftances were fenfibly diminifhed in the ftomachs of hens, even when inclofed in perforated tubes. Spallanzani himfelf fwallowed calcareous fubftances inclofed in tubes; and when he fed on vegetables and fruits, they were fometimes altered and a little diminifhed in weight, juft as if they had been put into weak vinegar; but when he ufed only animal food, they came out untouched. According to this philofopher, whofe experiments have been by far the moft numerous, the gaftric juice is naturally neither acid nor alkaline. When poured on the carbonat of potafs, it caufes no effervefcence.

Such are the refults of the experiments on the juices taken from the ftomach of animals. No conclufion can be drawn from them refpecting the nature of the gaftric juice. But from the experiments which have been made on the digeftion of the ftomach, efpecially by Spallanzani, the following facts are eftablifhed.

The gaftric juice attacks the furfaces of bodies, unites to the particles of them which it carries off, and cannot be feparated from them by filtration. It operates with more energy and rapidity the more the food is divided, and its action is increafed by a warm temperature. The food is not merely reduced to very minute parts; its tafte and fmell are quite changed; its fenfible properties are deftroyed, and it acquires new and very different ones. This juice does not act as a ferment; fo far from it, that it is a powerful antifeptic, and even reftores flefh already putrefied. There is not the fmalleft appearance of fuch a procefs; indeed, when the juice is renewed frequently, as in the ftomach, fubftances diffolve in it with a rapidity which excludes all idea of fermentation. Only a few air bubbles make their efcape, which adhere to the alimentary matter, and buoy it up to the top, and which are probably extricated by the heat of the folution.

Functions of Animals.

With refpect to the fubftances contained in the ftomach, only two facts have been perfectly afcertained: The firft is, that the juice contained in the ftomach of oxen, calves, fheep, invariably contains uncombined phofphoric acid, as Macquart and Vauquelin have demonftrated: The fecond, that the juice contained in the ftomach, and even the inner coat of the ftomach itfelf, has the property of coagulating milk and the ferum of blood. Dr Young found, that feven grains of the inner coat of a calf's ftomach, infufed in water, gave a liquid which coagulated more than 10[0] ounces of milk; that is to fay, more than 6857 times its own weight; and yet, in all probability, its weight was not much diminifhed.

What the fubftance is which poffeffes this coagulating property, has not yet been afcertained; but it is evidently not very foluble in water: for the infide of a calf's ftomach, after being fteeped in water for fix hours, and then well wafhed with water, ftill furnifhes a liquor on infufion which coagulates milk *: And Dr Young found, that a piece of the inner coat of the ftomach, after being previoufly wafhed with water, and then with a diluted folution of carbonat of potafs, ftill afforded a liquid which coagulated milk and ferum.

It is evident, from thefe facts, that this coagulating fubftance, whatever it is, acts very powerfully; and that it is fcarcely poffible to feparate it completely from the ftomach. But we know at prefent too little of the nature of coagulation to be able to draw any inference from thefe facts. An almoft imperceptible quantity of fome fubftances feems to be fufficient to coagulate milk. For Mr Vaillant mentions in his Travels in Africa, that a porcelain difh which he procured, and which had lain for fome years at the bottom of the fea, poffeffed, in confequence, the property of coagulating milk when put into it; yet it communicated no tafte to the milk, and did not differ in appearance from other cups.

It is probable that the faliva is of fervice in the converfion of food into chyme as well as the gaftric juice. It evidently ferves to dilute the food, and probably it may be ferviceable alfo, by communicating oxygen.

5. The chyme, thus formed, paffes from the ftomach into the inteftines, where it is fubjected to new changes, and at laft converted into two very different fubftances, chyle and excrementitious matter. [illegible]

6. The *chyle* is a white coloured liquid, very much refembling milk. It is exceedingly difficult to collect it in any confiderable quantity, and for that reafon it has never been accurately analyfed. We know only in general that it refembles milk; containing, like it, an albuminous part capable of being coagulated, a ferum, and globules which have a refemblance to cream. It contains alfo different falts; and, according to [illegible], a fubftance fcarcely differing from the fugar of milk. It is probable alfo that it contains iron; but if fo, it muft be

* Young[illegible]

be in the state of a white oxyd; for an infusion of nut galls does not alter the colour of chyle ‡.

6. Concerning the process by which chyle is formed from chyme, scarcely any thing is known. It does not appear that the chyme is precisely the same in all animals; for those which are herbivorous have a greater length of intestine than those which are carnivorous. It is certain that the formation of the chyle is brought about by a chemical change, although we cannot say precisely what that change is, or what the agents are by which it is produced. But that the change is chemical, is evident, because the chyle is entirely different, both in its properties and appearance, from the chyme. The chyme, by the action of the intestines, is separated into two parts, chyle and excrement: the first of which is absorbed by a number of small vessels called *lacteals*; the second is pushed along the intestinal canal, and at last thrown out of the body altogether.

After the chyme has been converted into chyle and excrement, although these two substances remain mixed together, it does not appear that they are able to decompose each other; for persons have been known seldom or never to emit any excrementitious matter *per anum* for years. In these, not only the chyle, but the excrementitious matter also, was absorbed by the lacteals; and the excrement was afterwards thrown out of the body by other outlets, particularly by the skin: in consequence of which, those persons have constantly that particular odour about them which distinguishes excrement. Now in these persons, it is evident that the chyle and excrement, though mixed together, and even absorbed together, did not act on each other; because these persons have been known to enjoy good health for years, which could not have been the case had the chyle been destroyed.

It has been supposed by some that the decomposition of the chyme, and the formation of chyle, is produced by the agency of the bile, which is poured out abundantly, and mixed with the chyme, soon after its entrance into the intestines. If this theory were true, no chyle could be formed whenever any accident prevented the bile from passing into the intestinal canal: but this is obviously not true; for frequent instances have occurred of persons labouring under jaundice from the bile ducts being stopped, either by gallstones or some other cause, so completely, that no bile could pass into the intestines; yet these persons have lived for a considerable time in that state. Consequently digestion, and therefore the formation of chyle, must be possible, independent of bile.

The principal use of the bile seems to be to separate the excrement from the chyle, after both have been formed, and to produce the evacuation of the excrement out of the body. It is probable that these substances would remain mixed together, and that they would perhaps even be partly absorbed together, were it not for the bile, which seems to combine with the excrement, and by this combination to facilitate its separation from the chyle, and thus to prevent its absorption. It also stimulates the intestinal canal, and causes it to evacuate its contents sooner than it otherwise would do; for when there is a deficiency of bile, the body is constantly costive.

341 Of the excrementitious matter.

8. The excrement, then, which is evacuated *per anum*, consists of all that part of the food and chyme which was not converted into chyle, entirely altered however from its original state, partly by the decomposition which it underwent in the stomach and intestines, and partly by its combination with bile. Accordingly we find in it many substances which did not exist at all in the food. Thus in the dung of cows and horses there is found a very considerable quantity of benzoic acid. The excrements of animals have not yet been subjected to an accurate analysis, though such an analysis would throw much light upon the nature of digestion. For if we knew accurately the substances which were taken into the body as food, and all the new substances which were formed by digestion; that is to say, the component parts of chyle and of excrement, and the variation which different kinds of food produce in the excrement, it would be a very considerable step towards ascertaining precisely the changes produced on food by digestion, or, which is the same thing, towards ascertaining exactly the phenomena of digestion. The only analysis which has hitherto been made on human excrement is that of Homberg; and as it consisted merely in subjecting it to distillation, it is needless to give an account of it. Of late, as Mr Fourcroy informs us, the subject has been resumed in France, and we may soon expect some very curious and important additions to our knowledge.

342 Excrements of fowls.

Mr Vauquelin has already published an analysis of the fixed parts of the excrements of fowls, and a comparison of them with the fixed parts of the food; from which some very curious consequences may be deduced.

He found that a hen devoured in ten days 11111.843 grains troy of oats. These contained

136.509 gr. of phosphat of lime,
219.548 silica,
———
356.057.

During these ten days she layed four eggs; the shells of which contained 98.776 gr. phosphat of lime, and 453.417 gr. carbonat of lime. The excrements emitted during these ten days contained 17[illegible] gr. phosphat of lime, 58.49[illegible] gr. of carbonat of lime, 185.266 gr. of silica. Consequently the fixed thrown out of the system during these ten days amounted to

Grains.
274.305 phosphat of lime,
511.911 carbonat of lime,
185.266 silica,
———
Given out 971.482
Taken in 356.057
———
615.425

Consequently the quantity of fixed matter given out of the system in ten days exceeded the quantity taken in by 615.425 grains.

The silica taken in amounted to	219.548 gr.
That given out was only	185.266 gr.
Remains	34.282

Consequently there disappeared 34.282 grains of silica.

The phosphat of lime taken in was	136.509 gr.
That given out was	274.305 gr.
	137.796

Consequently

‡ Fordyce on Digestion, 121.

Functions of Animals.

Functions of Animals.

Consequently there must have been formed, by digestion in this fowl, no less than 137.796 grains of phosphat of lime, besides 511.911 grains of carbonat. Consequently lime (and perhaps also phosphorus) is not a simple substance, but a compound, and formed of ingredients which exist in oat-seed, water, or air, the only substance to which the fowl had access. Silica may enter into its composition, as a part of the silica had disappeared; but if so, it must be combined with a great quantity of some other substance *.

These consequences are too important to be admitted without a very rigorous examination. The experiment must be repeated frequently, and we must be absolutely certain that the hen has no access to any calcareous earth, and that she has not diminished in weight; because in that case some of the calcareous earth, of which part of her body is composed, may have been employed. This rigour is the more necessary, as it seems pretty evident, from experiments made long ago, that *some* birds at least, cannot produce eggs unless they have access to calcareous earth. Dr Fordyce found, that if the canary bird was not supplied with lime at the time of her laying, she frequently died, from her eggs not coming forward properly †. He divided a number of these birds at the time of their laying eggs, into two parties: to the one he gave a piece of old mortar, which the little animals swallowed greedily; they laid their eggs as usual, and all of them lived: whereas many of the other party, which were supplied with no lime, died ‡.

† *On Digestion*, p. 25.

‡ *Ibid.* p. 26.

[342] Gases contained in the intestines.

9. The intestines seldom or never are destitute of gases, which seem to be evolved during the process of digestion §, and may therefore, in part, be considered as excrementitious matter. The only person who has examined these gases with care, is Mr Jurine of Geneva. The result of his analysis is as follows. He found in the stomach and intestines of a man who had been frozen to death, carbonic acid gas, oxygen gas, hydrogen gas, and azotic gas. The quantity of carbonic acid was greatest in the stomach, and diminished gradually as the canal receded from the stomach; the proportion of oxygen gas was considerable in the stomach, smaller in the small intestines, and still smaller in the great intestines; the hydrogen and azotic gases, on the contrary, were least abundant in the stomach, more abundant in the small intestines, and most abundant in the larger intestines; the hydrogen gas was most abundant in the small intestines. It is well known that the flatus discharged *per anum* is commonly carbonated hydrogen gas; sometimes also it seems to hold sulphur, or even phosphorus in solution §.

§ *Encyc. Meth. Med.* 516.

343 Chyle in the thoracic duct,

10. The chyle, after it has been absorbed by the lacteals, is carried by them into a pretty large vessel, known by the name of *thoracic duct*. Into the same vessel likewise is discharged a transparent fluid, conveyed by a set of vessels which arise from all the cavities of the body. These vessels are called *lymphatics*, and the fluid which they convey is called *lymph*. In the thoracic duct, then, the chyle and the lymph are mixed together.

344 Mixed with the lymph,

Very little is known concerning the nature of the *lymph*, as it is scarcely possible to collect it in any quantity. It is colourless, has some viscidity, and is said to be specifically heavier than water. It is said to be coagulable by heat; if so, it contains albumen; and, from its appearance, it probably contains gelatine. Its quantity is certainly considerable, for the lymphatics are very numerous.

11. The chyle and lymph being thus mixed together, are conveyed directly into the blood vessels. The effect produced by their union in the thoracic duct is not known, but neither the colour nor external properties of the chyle is altered. In man, and many other animals, the thoracic duct enters at the junction of the left subclavian and carotid veins, and the chyle is conveyed directly to the heart, mixed with the blood which already exists in the blood vessels. From the heart, the blood and chyle thus mixed together are propelled into the lungs, where they undergo farther changes.

346 Respiration.

12. The absolute necessity of *respiration*, or of something analogous, is known to every one; and few are ignorant that in man, and hot blooded animals, the organ by which respiration is performed is the lungs. For a description of the respiratory organs, we refer to the article ANATOMY, *Encycl.* and the reader will find an account of the manner in which that function is performed in the article PHYSIOLOGY, *Encycl.* But what are the changes produced upon the blood and the chyle by respiration? What purposes does it serve to the animal? How comes it to be so indispensably necessary for its existence? These are questions which can only be answered by a careful examination of the phenomena of respiration.

347 Requires oxygen gas.

It has been long known that an animal can only breathe a certain quantity of air for a limited time, after which it becomes the most deadly poison, and produces suffocation as effectually as the most noxious gas, or a total absence of air. It was suspected long ago that this change is owing to the absorption of a part of the air; and Mayow made a number of very ingenious experiments in order to prove the fact. Dr Priestley and Mr Scheele demonstrated, that the quantity of oxygen gas in atmospheric air is diminished; and Lavoisier demonstrated, in 1776, that a quantity of carbonic acid gas, which did not previously exist in it, was found in air after it had been for some time respired. It was afterwards proved by Lavoisier, and many other philosophers, who confirmed and extended his facts, that no animal can live in air totally destitute of oxygen. Even fish, which do not sensibly respire, die very soon, if the water in which they live be deprived of oxygen gas. Frogs which can suspend their respiration at pleasure, die in about forty minutes, if the water in which they have been confined be covered over with oil *. Insects and worms, as Vauquelin has proved, exhibit precisely the same phenomena. They require oxygen gas as well as other animals, and die like them if they be deprived of it. They diminish the quantity of the oxygen gas in which they live, and give out, by respiration, the very same products as other animals. Worms, which are more retentive of life than most other animals, or at least not so much affected by poisonous gases, absorb every particle of the oxygen gas contained in the air in which they are confined before they die. Mr Vauquelin's experiments were made on the gryllus viridissimus, the limax flavus, and helix pomatia †.

* *Carradori, Ann. de Chim.* xxix. 171.

† *Ann. de Chim.* xii. 278.

348 Changes produced by it.

The changes which take place during respiration are the following:

1. Part of the oxygen gas respired disappears.

2. Carbonic

Functions of Animals.

2. Carbonic acid gas is emitted.

3. Water is emitted in the state of vapour.

The first point is to ascertain exactly the amount of these changes. Though a great many experiments have been made on this subject by different philosophers, the greatest confidence ought to be put in those of Lavoisier, both on account of his uncommon accuracy, and on account of the very complete apparatus which he always employed.

He put a guinea-pig into 708.989 grains troy of oxygen, and after the animal had breathed the gas for an hour, he took it out. He found that the oxygen

gas now amounted only to	592.253 gr.
Consequently there had disappeared	116.736
The carbonic acid gas formed was	130.472
This was composed of about	94.234
oxygen, and	36.238

of carbon. Consequently supposing, as Mr Lavoisier did, that the oxygen absorbed had been employed in the formation of the carbonic acid gas, there still remained to be accounted for 22.502 grains of oxygen which had disappeared. He supposed that this had been employed in the formation of water, a quantity of which had appeared. If so, the water formed must have amounted to 26.429 grains; which was composed of 3.927 hydrogen, the rest oxygen *.

* Ann. de Chim. v. 261.

Since the water emitted was not actually ascertained, this experiment can only be considered as an approximation to the truth. Accordingly that very ingenious philosopher contrived an apparatus to ascertain the quantity of oxygen gas absorbed by man, and the quantity of carbonic acid gas and water emitted by him during respiration. This apparatus he had constructed at an expence at least equal to L. 500 sterling. The experiments were completed, and he was preparing them for publication, when, on the 8th of May 1794, he was beheaded by order of Robespierre, after having in vain requested a fortnight's delay to put his papers in order for the press. Thus perished, in the 51st year of his age, the man who, if he had lived a few years longer, promised fair to become the rival of Newton himself. Chemistry, as a science, is deeply indebted to him. He saved it from that confusion into which the thoughtless ardour of many of his contemporaries were plunging it headlong: he arranged and connected and simplified and explained the multitude of insulated facts, which had been accumulating with unexampled celerity; and which, had it not been for his happy arranging genius, might have retarded, instead of advanced, the progress of the science. He reduced all the facts under a few simple heads, and thus made them easily remembered and easily classified. In a few years more, perhaps, he would have traced these general principles to their sources, established the science on the completest induction, and paved for his successors a road as unerring as that which Sir Isaac Newton formed in mechanical philosophy.

Mr Lavoisier's experiments have never been published, but fortunately Mr de la Place has given us the result of them †. He informs us that it was as follows: A man, at an average, consumes, in twenty-four hours, by respiration, 32.48437 ounces troy of oxygen gas; that is to say, that a quantity of oxygen gas, equal to that weight, disappears from the air which he respires in twenty-four hours; that he gives out by respiration, in the same time, 15.73 oz. troy of carbonic acid gas, and 28.55 of water in the state of vapour.

† La Place's Eloge.

Total	44.28	*Oxygen.*
The carbonic acid gas is composed of and 5.243 carbon.		10.486
The water of and 4.2825 hydrogen.		24.2675
Total of the oxygen emitted		34.75416
Total absorbed		32.48437
So that there is		2.3697916

ounces of oxygen emitted more than is absorbed by respiration. Thus it appears that, by respiration, the absolute quantity of oxygen in the blood is diminished.

Dr Menzies found that a man, at a medium, draws in at every respiration 43.77 cubic inches of air, and that $\frac{1}{20}$th of that quantity disappears. Consequently, according to him, at every respiration 2.1885 cubic inches of oxygen gas are consumed. Now 2.1885 cubic inches of that gas amount to 0.68669 gr. troy. Supposing, with Hales, that a man makes 1200 respirations in an hour, the quantity of oxygen gas consumed in an hour, will amount to 824.028 grains, and in 24 hours to 19776.672 grains, or 41.2014 ounces troy. This quantity exceeds that found by Lavoisier considerably; but the allowance of oxygen for every respiration is rather too great. Indeed, from the nature of Dr Menzies's apparatus, it was scarce possible to measure it accurately.

The quantity of water given out by resp[illegible] determined by Hales, amounts in a day to [illegible] *; but his method was not susceptible of great accuracy. We may therefore, on the whole, consider Lavoisier's determination as by far the nearest to the truth of any that has been given.

* Veget. Stat. ii. 347.

There is, however, a very singular anomaly, which becomes apparent when we compare his experiments on the respiration of the guinea-pig with those on the respiration of man.

The guinea-pig consumed in 24 hours 5.8368 oz. troy of oxygen gas and emitted 6.5236 oz. of carbonic acid gas. Man, on the other hand, consumes in the same time 32.48437 oz. of oxygen gas, and emits only 15.73 oz. of carbonic acid gas. The oxygen gas consumed by the pig is to the carbonic gas emitted as 1.00 : 1.12; whereas in man it is as 1.000 : 0.484. If we could depend upon the accuracy of each of these experiments, they would prove, beyond a doubt, that the changes produced by the respiration of the pig are different, at least in degree, from those produced in man; but it is more than probable that some mistake has crept into one or other of the experiments. We have more reason to suspect the first, as it was made before 1778, at a time when a great many circumstances, necessary to insure accuracy, were unknown to Lavoisier.

Such are the substances imbibed and emitted during respiration. It still remains for us to determine what are the changes which it produces on the blood.

It has been long known that the blood which flows in the veins is of a dark reddish purple colour, whereas the arterial blood is of a florid scarlet colour. Lower observed that the colour of the veinous blood was converted into that of arterial during its passage through the

Functions of Animals. the lungs. No chyle can be distinguished by its white colour in the blood after it has passed through the lungs. The changes, then, which take place upon the appearance of the blood are two: 1*st*, It acquires a florid red colour; 2*d*, The chyle totally disappears. Now to what are these changes owing?

Lower himself knew that the change was produced by the air, and Mayow attempted to prove that it was by absorbing a part of the air. But it was not till Dr Priestley discovered that veinous blood acquires a scarlet colour when put in contact with oxygen gas, and arterial blood a dark red colour when put in contact with hydrogen gas, or, which is the same thing, that oxygen gas instantly gives veinous blood the colour of arterial; and hydrogen, on the contrary, gives arterial blood the colour of veinous blood: it was not till then that philosophers began to attempt any thing like an explanation of the phenomena of respiration. Two explanations have been given; one or other of which must be true.

349 Two hypotheses to explain these changes.

The first is, that the oxygen of the air, which disappears, combines with a quantity of carbon and hydrogen given out by the blood in the lungs, and forms with it carbonic acid gas and water in vapour, which are thrown out along with the air expired.

The second is, that the oxygen gas, which disappears, combines with the blood as it passes thro' the lungs; and that, at the instant of this combination, there is set free from the blood a quantity of carbonic acid gas and of water, which are thrown out along with the air expired.

The first of these theories was originally formed by Lavoisier, and it was embraced by La Place, Crawford, Gwen, and Girtanner, with a small variation. Indeed it does not differ, except in detail, from the original hypothesis of Dr Priestley, that the use of respiration is to rid the blood of phlogiston for if we substitute carbon and hydrogen for phlogiston, the two [illegible] precisely agree. Mr Lavoisier attempted not to pro[illegible] its truth; he only tried to shew that the oxygen absorbed corresponds exactly with the quantity of oxy[illegible] contained in the carbonic acid and the water emitted. This coincidence, however, experiments have shewn not to hold; consequently the [illegible] is entirely destitute of proof, as far as the proof depends upon this coincidence.

The other hypothesis was proposed by Mr de la Grange, and afterwards supported and illustrated by Mr Hassenfratz.

350 Effects of respiration examined.

In order to discover what the real effects of respiration are, let us endeavour to state accurately the phenomena as far as possible.

In the *first* place, we are certain, from the experiments of Priestley, Girtanner, and Hassenfratz, that when veinous blood is exposed to oxygen gas confined over it, the blood instantly assumes a scarlet colour, and the gas is diminished in bulk; therefore part of the gas has been absorbed. We may consider it as certain, then, that when the colour of veinous blood is changed into arterial, some oxygen gas is absorbed †.

In the *second* place, no chyle can be discovered in the blood after it has passed through the lungs. Therefore the *white colour* of the chyle at least, is destroyed by respiration, and it assumes a red colour. Now if the red colour of the blood be owing to iron, as many have supposed, this change of colour is a demonstration that oxygen has combined with the iron; for we have seen already, that iron, if it exists in chyle, as it probably does, is in the state of a white oxyd. Consequently, when converted into a red oxyd, it must absorb oxygen. Even though iron be not the colouring matter of the blood, it would still be probable that the change of colour of the chyle depends on the fixation of oxygen; for Berthollet and Fourcroy have shewn that in several instances substances acquire a red colour by that process.

We may consider it as proved, then, that oxygen enters the blood as it passes through the lungs.

In the *third* place, when arterial blood is put in contact with azotic gas, or carbonic acid gas, it gradually assumes the dark colour of veinous blood, as Dr Priestley found *. The same philosopher also observed that arterial blood acquired the colour of veinous blood when placed in vacuo †. Consequently this alteration of colour is owing to some change which takes place in the blood itself, independent of any external agent.

The arterial blood becomes much more rapidly and deeply dark coloured when it is left in contact with hydrogen gas placed above it ‡. We must suppose therefore that the presence of this gas accelerates and increases the change, which would have taken place upon the blood without any external agent.

If arterial blood be left in contact with oxygen gas, it gradually assumes the same dark colour which it would have acquired in vacuo, or in contact with hydrogen; and after this change oxygen can no longer restore its scarlet colour §. Therefore it is only upon a part of the blood that the oxygen acts; and after this part has undergone the change which occasions the dark colour, the blood loses the power of being affected by oxygen.

Mr Hassenfratz poured into veinous blood a quantity of oxy-muriatic acid; the blood was instantly decomposed, and assumed a deep and almost black colour. When he poured common muriatic acid into blood, the colour was not altered ‖. Now oxy muriatic acid has the property of giving out its oxygen readily; consequently the black colour was owing to the instant combination of a part of the blood with oxygen.

The facts therefore lead us to conclude, with La Grange and Hassenfratz, that during respiration the oxygen, which disappears, enters the blood; that during the circulation this oxygen combines with a certain part of the blood; and that the veinous colour is owing to this new combination. We must conclude, too, that the substance which causes this dark colour leaves the blood during its circulation thro' the lungs, otherwise it could not be capable of assuming the florid colour. Now we know what the substances are which are emitted during respiration; they are water and carbonic acid gas. It must be to the gradual combination of oxygen, then, during the circulation, with hydrogen and carbon, that the colour of veinous blood is owing. And since the same combination takes place every time that the blood passes through the lungs, we must conclude, that it is only a part of the hydrogen and carbon which is acted upon each time. Let us now attempt, with these data, to form some notion of the decomposition which goes on during the circulation of the blood.

351 Contributes to the formation of blood,

It is probable that, during a considerable part of the day, there is a constant influx of chyle into the blood; and we are certain that lymph is constantly flowing into

† *Ann de Chim.* vii. 148.

* *Priestley*, iii 363.

§ *Ibid* ix. 268.

‖ *Ibid.*

Functions of Animals.

to it. Now it appears, from the most accurate observations hitherto made, that neither chyle nor lymph contain fibrina, which forms a very conspicuous part of the blood. This fibrina is employed to supply the waste of the muscles, the most active parts of the body, and therefore, in all probability, requiring the most frequent supply. Nor can it be doubted that it is employed for other useful purposes. The quantity of fibrina in the blood, then, must be constantly diminishing, and therefore new fibrina must be constantly formed. But the only substances out of which it can be formed are the chyle and lymph, neither of which contain it. There must therefore be a continual decomposition of the chyle and lymph going on in the blood-vessels, and a continual new formation of fibrina. Other substances also may be formed; but we are certain that this *must* be formed there, because it does not exist previously. Now, one great end of respiration must undoubtedly be to assist this decomposition of chyle and complete formation of blood.

It follows, from the experiments of Fourcroy formerly enumerated, that fibrina contains more azot, and less hydrogen and carbon, than any of the other ingredients of the blood, and consequently also than any of the ingredients of the chyle. In what manner the chyle, or a part of it, is converted into fibrina, it is impossible to say: we are not sufficiently acquainted with the subject to be able to explain the process. But we can see at least, that carbon and hydrogen must be abstracted from that part of the chyle which is to be converted into fibrina: And we know, that these substances are actually thrown out by respiration. We may conclude, then, that *one* use of the oxygen absorbed is, to abstract a quantity of carbon and hydrogen from a part of the chyle by compound affinity, in such proportions, that the remainder becomes fibrina: therefore one end of respiration is to form fibrina. Doubtless the other ingredients of the blood are also new modified, though we know too little of the subject to throw any light upon it.

512 Produces animal heat;

13. But the complete formation of blood is not the only advantage gained by respiration: the *temperature* of all animals depends upon it. It has been long known, that those animals which do not breathe have a temperature but very little superior to the medium in which they live. This is the case with fishes and many insects. Man, on the contrary, and quadrupeds which breathe, have a temperature considerably higher than the atmosphere: that of man is 98°. Birds, who breathe in proportion a still greater quantity of air than man, have a temperature equal to 103° or 104°. It has been proved, that the temperature of all animals is proportional to the quantity of air which they breathe in a given time.

These facts are sufficient to demonstrate, that the heat of animals depends upon respiration. But it was not till Dr Black's doctrine of latent heat became known to the world, that any explanation of the cause of the temperature of breathing animals was attempted. That illustrious philosopher, whose discoveries form the basis upon which all the scientific part of chemistry has been reared, saw at once the light which his doctrine of latent heat threw upon this part of physiology, and he applied it very early to explain the temperature of animals.

According to him, part of the latent heat of the air inspired becomes sensible; and of course, the temperature of the lungs, and the blood that passes through them, must be raised; and the blood, thus heated, communicates its heat to the whole body. This opinion was ingenious, but it was liable to an unanswerable objection: for if it were true, the temperature of the body ought to be greatest in the lungs, and to diminish gradually as the distance from the lungs increases; which is not true. The theory, in consequence, was abandoned even by Dr Black himself; at least he made no attempt to support it.

Lavoisier and Crawford, who considered all the changes operated by respiration as taking place in the lungs, accounted for the origin of the animal heat almost precisely in the same manner with Dr Black. According to them, the oxygen gas of the air combines in the lungs with the hydrogen and carbon emitted by the blood. During this combination, the oxygen gives out a great quantity of caloric, with which it had been combined; and this caloric is not only sufficient to support the temperature of the body, but also to carry off the new formed water in the state of vapour, and to raise considerably the temperature of the air inspired. According to these philosophers, then, the whole of the caloric which supports the temperature of the body is evolved in the lungs. Their theory accordingly was liable to the same objection with Dr Black's; but they obviated it in the following manner: Dr Crawford found, that the specific caloric of arterial blood was 1,0300, while that of veinous blood was only 0,8928. Hence he concluded, that [illegible] veinous blood is changed into arterial [illegible] consequently it [illegible] quantity of caloric to keep its [illegible] veinous blood. [illegible] the whole new caloric [illegible] employed; therefore the temperature of the [illegible] remain the same as that of the [illegible] the circulation, arterial blood is [illegible] consequently its specific [illegible] give out heat. This [illegible] of the extreme parts [illegible] diminish.

This explanation [illegible] ingenious, but it is not q[illegible] difference in the specific caloric, granting it to be accurate, is too small to account for the great quantity of heat which must be evolved. It is evident that it must fall to the ground altogether, provided, as we have seen reason to suppose, the carbonic acid gas and water be not formed in the lungs, but during the circulation.

Since the oxygen enters the blood, and combines with it in the state of gas, it is evident that it will only part at first with some of its caloric; and this portion is chiefly employed in carrying off the carbonic acid gas and the water. For the reason that the carbonic acid leaves the blood at the instant that the oxygen gas enters it, seems to be this: The oxygen gas combines with the blood, and part of its caloric unites at the same instant to the carbonic acid, and converts it into gas: another portion converts the water into vapour. The rest of the caloric is evolved during the circulation when the oxygen combines with hydrogen and carbon, and forms water and carbonic acid gas. The quantity of caloric evolved in the lungs seems not only sufficient to carry off the carbonic acid and water, which the diminution

Functions of Animals. nution of the specific caloric (if it really take place) must facilitate; but it seems also to raise the temperature of the blood a little higher than it was before. For Mr John Hunter constantly found, that the heat of the heart in animals was a degree higher than any other part of the body which he examined. Now this could scarcely happen, unless the temperature of the blood were somewhat raised during respiration.

353 And supports the circulation. Thus we have seen two uses which respiration seems to serve. The first is the completion of blood by the formation of fibrina; the second is the maintaining of the temperature of the body at a particular standard, notwithstanding the heat which it is continually giving out to the colder surrounding bodies. But there is a third purpose, which explains why the animal is killed so suddenly when respiration is stopped. The circulation of the blood is absolutely necessary for the continuance of life. Now the blood is circulated in a great measure by the alternate contractions of the heart. It is necessary that the heart should contract regularly, otherwise the circulation could not go on. But the heart is stimulated to contract by the blood: and, unless blood be made to undergo the change produced by respiration, it ceases almost instantaneously to stimulate. As the blood receives oxygen in the lungs, we may conclude that the presence of oxygen is necessary to its stimulating power *.

* Girtanner, Jour. de Phys. xxxix.

354 Kidneys employed in the formation of blood. 14. Thus we have reason to suppose, that chyle and lymph are converted into blood during the circulation; and that the oxygen gas supplied by respiration is one of the principal agents in this change. But besides the lungs and arteries, there is another organ, the sole use of which is also to produce some change or other in the blood, which renders it more complete, and more proper for the various purposes to which it is applied. This organ is the *kidney*.

For the structure of the kidneys, which in man and quadrupeds are two in number, we refer to ANATOMY, *Index*. A very great proportion of blood passes thro' them; indeed, we have every reason to conclude, that the whole of the blood passes through them very frequently.

These organs separate the urine from the blood, to be afterwards evacuated without being applied to any purpose useful to the animal.

The kidneys are absolutely necessary for the continuance of the life of the animal; for it dies very speedily when they become by disease unfit to perform their functions: therefore the change which they produce in the blood is a change necessary for qualifying it to answer the purposes for which it is intended.

As the urine is immediately excreted, it is evident that the change which the kidneys perform is intended solely for the sake of the blood. It is not merely the abstraction of a quantity of water and of salts, accumulated in the blood, which the kidney performs. A chemical change is certainly produced, either upon the whole blood, or at least on some important part of it; for there are two substances found in the urine which do not exist in the blood. These two substances are urea and uric acid. They are formed, therefore, in the kidneys; and as they are thrown out, after being formed, without being applied to any useful purpose, they are certainly not formed in the kidneys for their own sake. Some part of the blood, then, must be decomposed in the kidney, and a new substance, or new substances, must be formed; and the ur [illegible] id must be formed at the same time, in consequence of the combined action of the affinities which [illegible] uce the change on the blood; and being useless, they are thrown out, together with a quantity of water and salts, which, in all probability, were useful in bringing about the changes which take place in the arteries and in the kidneys, but which are no longer of any service after these changes are brought about.

The changes operated upon the blood in the kidneys are hitherto altogether unknown; but they must be important.

355 Cutaneous vessels. Provided the method of analysing animal substances were so far perfected as to admit of accurate conclusions, considerable light might be thrown upon this subject, by analysing with care a portion of blood from the emulgent vein and artery separately, and ascertaining precisely in what particulars they differ from each other.

15. Thus we have seen that the principal changes which the blood undergoes, as far at least as we are at present acquainted with them, take place in the lungs, in the kidneys, and in the arteries. In the lungs, a quantity of water and carbonic acid gas is emitted from the blood, and in the kidney the urine is formed and separated from it. There seems also to be something thrown out from the blood during its circulation in the arteries, at least through those vessels which are near the surface of the body: For it is a fact, that certain substances are constantly emitted from the skins of animals. These substances are known in general by the name of *perspirable matter*, or *perspiration*. They have a great resemblance to what is emitted in the lungs; which renders it probable, that they are both owing to the same cause; namely, to the decomposition produced in the blood by the effects of respiration. They consist chiefly of water in a state of vapour, carbon, and oil.

356 Emit aqueous vapour. The quantity of aqueous vapour differs very considerably, according to circumstances. It has been shewn to be greatest in hot weather, and in hot climates, and after great exercise; and its relation to the quantity of urine has been long known. When the aqueous vapour perspired is great, the quantity of urine is small, and *vice versa*.

The most accurate experiments on this matter that we have seen are those of Mr Cruikshank. He put his hand into a glass vessel, and luted its mouth at his wrist by means of a bladder. The interior surface of the vessel became gradually dim, and drops of water trickled down. By keeping his hand in this manner for an hour, he collected 30 grains of a liquid, which possessed all the properties of pure water *. On repeating the same experiment at nine in the evening (thermometer 62°), he collected only 12 grains. The mean of these is 21 grains. But as the hand is more exposed than the trunk of the body, it is reasonable to suppose that the perspiration from it is greater than that from the hand. Let us therefore take 30 grains per hour as the mean; and let us suppose, with Mr Cruikshank, that the hand is $\frac{1}{60}$th of the surface of the body. The perspiration in an hour would amount to 1800 grains, and in 24 hours to 43200 grains, or 7 pounds 6 ounces troy.

* On Insensible Perspiration, p. 68.

He

He repeated the experiment again after hard exercise, and collected in an hour 48 grains of water*. He found also, that this aqueous vapour pervaded his stocking without difficulty; and that it made its way thro' a shamoy leather glove, and even through a leather boot, though in much smaller quantity than when the leg wanted that covering†.

* On Insensible Perspiration, p. 7..

† Ibid p. 82.

It is not difficult to see why the quantity of watery vapour diminishes with cold. When the surface of the body is exposed to a cold temperature, the capacity of the cutaneous vessels diminishes, and consequently the quantity which flows through them must decrease

When the temperature, on the other hand, is much increased, either by being exposed to a hot atmosphere, or by violent exercise, the perspired vapour not only increases in quantity, but even appears in a liquid form. This is known by the name of *sweat*. In what manner sweat is produced, is not at present known; but we can see a very important service which it performs to the animal.

No sooner is it thrown upon the surface of the skin than it begins to evaporate. But the change into vapour requires heat; accordingly a quantity of heat is absorbed, and the temperature of the animal is lowered. This is the reason that animals can endure to remain for some time in a much higher temperature without injury than could have been supposed.

The experiments of Tillet, and the still more decisive experiments of Fordyce and his associates, are well known. These gentlemen remained a considerable time in a temperature exceeding the boiling point of water.

357 Carbon, Besides water, it cannot be doubted that *carbon* is also emitted from the skin; but in what state, the experiments hitherto made do not enable us to decide. Mr Cruikshank found, that the air of the glass vessel in which his hand and foot had been confined for an hour, contained carbonic acid gas; for a candle burned dimly in it, and it rendered lime-water turbid*. And Mr Jurine found, that air which had remained for some time in contact with the skin, consisted almost entirely of carbonic acid gas†. The same conclusion may be drawn from the experiments of Ingenhousz and Milly‡.

* Ibid. p. 70 and 81

† Enc. Meth. Med. i. p. 515.

‡ Ibid. p. 511.

Now it is evident, that the carbonic acid gas which appeared during Mr Cruikshank's experiment, did not previously exist in the glass vessel; consequently it must have either been transmitted ready formed through the skin, or formed during the experiment by the absorption of oxygen gas, and the consequent emission of carbonic acid gas. The experiments of Mr Jurine do not allow us to suppose the first of these to be true; for he found, that the quantity of air allowed to remain in contact with the skin did not increase. Consequently the appearance of the carbonic acid gas must be owing, either to the emission of carbon, which forms carbonic acid gas by combining with the oxygen gas of the air, or to the absorption of oxygen gas, and the subsequent emission of carbonic acid gas, precisely in the same manner, and for the same reason, that these substances are emitted by the lungs. The last is the more probable opinion; but the experiments hitherto made do not enable us to decide.

358 And an oily matter. Besides water and carbon, or carbonic acid gas, the skin emits also a particular odorous substance. That every animal has a peculiar smell, is well known: the dog can discover his master, and even trace him to a distance by the scent. A dog, chained some hours after his master had set out on a journey of some hundred miles, followed his footsteps by the smell, and found him on the third day in the midst of a crowd*. But it is needless to multiply instances of this fact; they are too well known to every one. Now this smell must be owing to some peculiar matter which is constantly emitted; and this matter must differ somewhat either in quantity or some other property, as we see that the dog easily distinguishes the individual by means of it. Mr Cruikshank has made it probable that this matter is an oily substance; or at least that there is an oily substance emitted by the skin. He wore repeatedly, night and day for a month, the same vest of fleecy hosiery during the hottest part of the summer. At the end of this time he always found an oily substance accumulated in considerable masses on the nap of the inner surface of the vest, in the form of black tears. When rubbed on paper, it makes it transparent, and hardens on it like grease. It burns with a white flame, and leaves behind it a charry residuum†.

* Cruikshank, ibid. p. 93.

† Ibid. p. 91.

It has been supposed that the skin has the property of *absorbing moisture* from the air; but this opinion has not been confirmed by experiments, but rather the contrary.

359 Whether the skin absorbs moisture, The chief arguments in favour of the absorption of the skin, have been drawn from the quantity of moisture discharged by urine being, in some cases, not only greater than the whole drink of the patient, but even than the whole of his drink and food. But it ought to be remembered that, in diabetes, the disease here alluded to, the weight of the body is continually diminishing, and therefore part of it must be constantly thrown off. Besides, it is scarcely possible in that disease to get an accurate account of the food swallowed by the patients; and in those cases where very accurate accounts have been kept, and where deception was not so much practised, the urine was found not to exceed the quantity of drink*. In a case of diabetes, related with much accuracy by Dr Gerard, the patient was bathed regularly during the early part of the disease in warm water, and afterwards in cold water: he was weighed before and after bathing, and no sensible difference was ever found in his weight†. Consequently, in that case, the quantity absorbed, if any, must have been very small.

* See Rollo on Diabetes.

† Ibid. ii. 73.

It is well known, that thirst is much alleviated by cold bathing. By this plan, Captain Bligh kept his men cool and in good health during their very extraordinary voyage across the South Sea. This has been considered as owing to the absorption of water by the skin. But Dr Currie had a patient who was wasting fast for want of nourishment, a tumor in the œsophagus preventing the possibility of taking food, and whose thirst was always alleviated by bathing; yet no sensible increase of weight, but rather the contrary, was perceived after bathing. It does not appear, then, that in either of these cases water was absorbed.

Farther, Seguin has shewn that the skin does not absorb water during bathing, by a still more complete experiment: He dissolved some mercurial salt in water, and found that the mercury produced no effect upon a person that bathed in the water, provided no part of the

the cuticle was injured; but upon rubbing off a portion of the cuticle, the mercurial ſolution was abſorbed, and the effects of the mercury became evident upon the body. Hence it follows irreſiſtibly, that water, at leaſt in the ſtate of *water*, is not abſorbed by the ſkin when the body is plunged into it, unleſs the cuticle be firſt removed.

360 Or any other ſub. This may perhaps be conſidered as a complete proof that no ſuch thing as abſorption is performed by the ſkin; and that therefore the appearance of carbonic acid gas, which takes place when air is confined around the ſkin, muſt be owing to the emiſſion of carbon. But it ought to be conſidered, that although the ſkin cannot abſorb water, this is no proof that it cannot abſorb other ſubſtances; particularly, that it cannot abſorb oxygen gas, which is very different from water. It is well known, that water will not paſs through bladders, at leaſt for ſome time; yet Dr Prieſtley found that veinous blood acquired the colour of arterial blood from oxygen gas, as readily when theſe ſubſtances were ſeparated by a bladder as when they were in actual contact. He found, too, that when gaſes were confined in bladders, they gradually loſt their properties. It is clear from theſe facts, that oxygen gas can pervade bladders; and if it can pervade them, why may it not alſo pervade the cuticle? Nay, farther, we know from the experiments of Cruikſhank, that the vapour perſpired paſſes through leather, even when prepared ſo as to keep out moiſture, at leaſt for a certain time. It is poſſible, then, that water, when in the ſtate of vapour, or when diſſolved in air, may be abſorbed, although water, while in the ſtate of water, may be incapable of pervading the cuticle. The experiments, then, which have hitherto at leaſt been made upon the abſorption of the ſkin, are altogether inſufficient to prove that air and vapour cannot pervade the cuticle; provided at leaſt there be any facts to render the contrary ſuppoſition probable.

Now that there are ſuch facts cannot be denied. We ſhall not indeed produce the experiment of Van Mons as a fact of that kind, becauſe it is liable to objections, and at beſt is very undeciſive. Having a patient under his care who, from a wound in the throat, was incapable for ſeveral days of taking any nouriſhment, he kept him alive during that time, by applying to the ſkin in different parts of the body, ſeveral times a day, a ſponge dipt in wine or ſtrong ſoup *. A fact mentioned by Dr Watſon is much more important, and much more deciſive. A lad at Newmarket, who had been almoſt ſtarved in order to bring him down to ſuch a weight as would qualify him for running a horſe race, was weighed in the morning of the race day; he was weighed again juſt before the race began, and was found to have gained 30 ounces of weight ſince the morning; yet in the interval he had only taken a ſingle glaſs of wine. Here abſorption muſt have taken place, either by the ſkin, or lungs, or both. The difficulties in either caſe are the ſame; and whatever renders abſorption by one probable, will equally ſtrengthen the probability that abſorption takes place by the other (R).

16. We have now ſeen the proceſs of digeſtion, and the formation of blood, as far at leaſt as we are acquainted with it. But to what purpoſes is this blood employed, which is formed with ſo much care, and for the formation of which ſo great an apparatus has been provided? It anſwers two purpoſes. The parts of which the body is compoſed, bones, muſcles, ligaments, membranes, &c. are continually changing. In youth they are increaſing in ſize and ſtrength, and in mature age they are continually acting, and conſequently continually liable to waſte and decay. They are often expoſed to accidents, which render them unfit for performing their various functions; and even when no ſuch accident happens, it ſeems neceſſary for the health of the ſyſtem that they ſhould be every now and then renewed. Materials therefore muſt be provided for repairing, increaſing, or renewing all the various organs of the body. Phoſphat of lime and gelatine for the bones, fibrina for the muſcles, albumen for the cartilages and membranes, &c. Accordingly all theſe ſubſtances are laid up in the blood; and they are drawn from that fluid as from a ſtorehouſe whenever they are required. The proceſs by which the different parts of the blood are made part of the various organs of the body is called *aſſimilation*. 361 Blood ſupplies the waſte of the ſyſtem.

362 Aſſimilation. Over the nature of aſſimilation the thickeſt darkneſs ſtill hangs; there is no key to explain it, nothing to lead us to the knowledge of the inſtruments employed. Facts, however, have been accumulated in ſufficient numbers to put the exiſtence of the proceſs beyond the reach of doubt. The healing, indeed, of every fractured bone, and every wound of the body, is a proof of its exiſtence, and an inſtance of its action.

363 Every aſſimilating organ produces a peculiar change, Every organ employed in aſſimilation has a peculiar office; and it always performs this office whenever it has materials to act upon, even when the performance of it is contrary to the intereſt of the animal. Thus the ſtomach always converts food into chyme, even when the food is of ſuch a nature that the proceſs of digeſtion will be retarded rather than promoted by the change. If warm milk, for inſtance, or warm blood, be thrown into the ſtomach, they are always decompoſed by that organ, and converted into chyme; yet theſe ſubſtances are much more nearly aſſimilated to the animal before the action of the ſtomach than after it. The ſame thing happens when we eat animal food.

364 And no other change. On the other hand, a ſubſtance introduced into an organ employed in aſſimilation, if it has undergone preciſely the change which that organ is fitted to produce, is not acted upon by that organ, but paſſed on unaltered to the next aſſimilating organ. Thus it is the office of the inteſtines to convert chyme into chyle. Accordingly, whenever chyme is introduced into the inteſtines, they perform their office, and produce the uſual change; but if chyle itſelf be introduced into the inteſtines, it is abſorbed by the lacteals without alteration. The experiment, indeed, has not been tried with true chyle, becauſe it is ſcarce poſſible to procure it in ſufficient quantity; but when milk, which reſembles chyle pretty accurately, is thrown into the jejunum, it is abſorbed unchanged by the lacteals *.

* Fordyce on Digeſtion, p. 159.

Again,

(R) The Abbé Fontana alſo found, that after walking in moiſt air for an hour or two, he returned home ſome ounces heavier than he went out, notwithſtanding he had ſuffered conſiderable evacuation from a briſk purge purpoſely taken for the experiment. This increaſe, indeed, might be partly accounted for by the abſorption of moiſture by his clothes.

Functions of Animals.

Again, the office of the blood vessels, as assimilating organs, is to convert chyle into blood. Chyle, accordingly, cannot be introduced into the arteries without undergoing that change; but *blood* may be introduced from another animal without any injury, and consequently without undergoing any change. This experiment was first made by Lower, and it has since been very often repeated.

Also, if a piece of fresh muscular flesh be applied to the muscle of an animal, they adhere and incorporate without any change, as has been sufficiently established by the experiments of Mr J. Hunter. And Buvina has ascertained, that fresh bone may, in the same manner, be engrafted on the bones of animals of the same or of different species †.

† *Phil. Mag.* vi. 308.

In short, it seems to hold, at least as far as experiments have hitherto been made, that foreign substances may be incorporated with those of the body, provided they be precisely of the same kind with those to which they are added, whether fluid or solid. Thus chyle may be mixed with chyle, blood with blood, muscle with muscle, and bone with bone. The experiment has not been extended to the other animal substances, the nerves, for instance; but it is extremely probable that it would hold with respect to them also.

On the other hand, when substances are introduced into any part of the body which are not the same with that part, nor the same with the substance upon which that part acts; provided they cannot be thrown out readily, they destroy the part, and perhaps even the animal. Thus foreign substances introduced into the blood very soon prove fatal; and introduced into wounds of the flesh or bones, they prevent these parts from healing.

365 Their power limited.

Although the different assimilating organs have the power of changing certain substances into others, and of throwing out the useless ingredients, yet this power is not absolute, even when the substances on which they act are proper for undergoing the change which the organs produce. Thus the stomach converts food into chyme, the intestines chyme into chyle, and the substances which have not been converted into chyle are thrown out of the body. If there happen to be present in the stomach and intestines any substance which, though incapable of undergoing the changes, at least, by the action of the stomach and intestines, yet has a strong affinity, either for the whole chyme and chyle, or for some particular part of it, and no affinity for the substances which are thrown out, that substance passes along with the chyle, and in many cases continues to remain chemically combined with the substance to which it is united in the stomach, even after that substance has been completely assimilated, and made a part of the body of the animal. Thus there is a strong affinity between the colouring matter of madder and phosphat of lime. Accordingly, when madder is taken into the stomach, it combines with the phosphat of lime of the food, passes with it through the lacteals and blood vessels, and is deposited with it in the bones, as was proved by the experiments of Duhamel. In the same manner musk, indigo, &c. when taken into the stomach, make their way into many of the secretions.

These facts shew us, that assimilation is a chemical process from beginning to end; that all the changes are produced according to the laws of chemistry; and that we can even derange the regularity of the process by introducing substances whose mutual affinities are too strong for the organs to overcome.

366 Assimilation a chemical process;

It cannot be denied, then, that the assimilation of food consists merely in a certain number of chemical decompositions which that food undergoes, and the consequent formation of certain new compounds. But are the *agents* employed in assimilation merely chemical agents? We cannot produce any thing like these changes on the food out of the body, and therefore we must allow that they are the consequence of the action of the animal organs. But this action, it may be said, is merely the secretion of particular juices, which have the property of inducing the wished for change upon the food; and this very change would be produced out of the body, provided we could procure these substances, and apply them in proper quantity to the food. If this supposition be true, the specific action of the vessels consists in the secretion of certain substances; consequently the cause of this secretion is the *real* agent in assimilation. Now, can the *cause* of this secretion be shewn to be merely a chemical agent? Certainly not. For in the stomach, where only this secretion can be shewn to exist, it is not always the same, but varies according to circumstances. Thus eagles at first cannot digest grain, but they may be brought to do it by persisting in making them use it as food. On the contrary, a lamb cannot at first digest animal food, but habit will also give it this power. In this case, it is evident that the gastric juice changes according to circumstances. Now this is so far from being a case of a chemical law, that it is absolutely incompatible with every such law. The agent in assimilation, then, is not a chemical agent, but one which acts upon different principles. It is true, indeed, that every [illegible] the process is chemical; but the agent which [illegible] these chemical processes, which prevents them [illegible]g, except in particular circumstances and on [illegible] substances, and modifies this action according [illegible]stances, is not a mere chemical agent, but endowed [illegible] very different properties.

367 But the agent not chemical.

The presence and power of [illegible]nt will be still more evident, if we consider [illegible]ity of the stomach of the living animal during the process of digestion. The stomach of animals is as fit for food as any other substance. The gastric juice, therefore, must have the same power of acting on it, and of decomposing it, that it has of acting on other substances; yet it is well known that the stomach is not affected by digestion while the animal retains life; though, as Mr Hunter ascertained, the very gastric juice which the living stomach secretes often dissolves the stomach itself after death. Now what is the power which prevents the gastric juice from acting on the stomach during life? Certainly neither a chemical nor mechanical agent, for these agents must still retain the same power after death. We must, then, of necessity conclude, that there exists in the animal an agent very different from chemical and mechanical powers, since it controuls these powers according to its pleasure. These powers therefore in the living body are merely the servants of this superior agent, which directs them so as to accomplish always one particular end. This agent seems to regulate the chemical powers, chiefly by bringing only certain substances together which are to be decomposed, and by keeping at a distance those substances which would interfere with, or diminish, or spoil the product, or

injure

Functions of Animals.

injure the organ. And we see that this separation is always attended to even when the substances are apparently mixed together. For the very same products are not obtained which would be obtained by mixing the same substances together out of the body that are produced by mixing them in the body; consequently all the substances are not left at full liberty to obey the laws of their mutual affinities. The superior agent, however, is not able to exercise an unlimited authority over the chemical powers; sometimes they are too strong for it: some substances accordingly, as madder, make their way into the system; while others, as arsenic, decompose and destroy the organs of the body themselves.

But it is not in digestion alone that this superior agent makes the most wonderful display of its power; it is in the last part of assimilation that our admiration is most powerfully excited. How comes it that the precise substances wanted are always carried to every organ of the body? How comes it that fibrina is always regularly deposited in the muscles, and phosphat of lime in the bones? And what is still more unaccountable, how comes it that prodigious quantities of some one particular substance are formed and carried to a particular place in order to supply new wants which did not before exist? A bone, for example, becomes diseased and unfit for the use of the animal; a new bone therefore is formed in its place, and the old one is carried off by the absorbents. In order to form this new bone, large quantities of phosphat of lime are deposited in a place where the same quantity was not before necessary. Now, who informs this agent that an unusual quantity of phosphat of lime is necessary, and that it must be carried to that particular place? Or granting, as is most probable, that the phosphat of lime of the old bone is partly employed for this purpose, who taught this agent that the old bone must be carried off, new modelled, and deposited, and assimilated anew? The same wonders take place during the healing of every wound, and the renewing of every diseased part.

These operations are incompatible with the supposition that the body of animals is a mere chemical and mechanical machine; and demonstrate the presence of some agent besides, which acts according to very different laws.

But neither in this case is the power of this agent over the chemical agents, which are employed, absolute. We may prevent a fractured bone from healing by giving the patient large quantities of acids. And unless the materials for the new wanted substances be supplied by the food, they cannot, in many cases, be formed at all. Thus the canary bird cannot complete her eggs unless she be furnished with lime.

It is evident that the supreme agent of the animal body, whatever that agent may be, acts according to fixed laws; and that when these laws are opposed by those which are more powerful, it cannot overcome them. These laws clearly indicate design; and the agent has the power of modifying them somewhat according to circumstances. Thus more phosphat of lime is sent to a limb which requires a new bone, and more lime than usual is taken into the system when the hen is laying eggs. Design and contingency are considered by us as infallible marks of consciousness and intelligence. That they are infallible marks of the agency of mind is certain; but that they are in all cases the proofs of immediate consciousness and intelligence, as the Stahlians supposed, cannot be affirmed without running into inconsistencies. For we ourselves are not conscious of those operations which take place during *assimilation*.

To say that a being can act with design without intelligence, we allow to be a flat contradiction, because design always implies intelligence. There must therefore be intelligence somewhere. But may not this intelligence exist, not in the agent, but in the being who formed the agent? And may not the whole of the design belong in reality to that being?

368 Not matter.

May not this agent, then, be material, and may not the whole of assimilation be performed by mere matter, acting according to laws given it by its maker? We answer, that what is called *matter*, or the substances enumerated in the first part of CHEMISTRY (*Suppl.*) act always according to certain attractions and repulsions, which are known by the name of mechanical and chemical laws.

The phenomena of assimilation are so far from being cases of these laws, that they are absolutely inconsistent with them, and contrary to them; consequently the agent which presides over *assimilation* is not *matter*. Concerning the nature of this substance it is not the business of this article to inquire; but as it possesses properties different from matter, and acts according to very different laws, it would be an abuse of terms to call it *matter*.

369 Animal principle.

We would give it the name of *mind*, were it not that metaphysicians have chosen to consider intelligence as the essence of mind; whereas this substance may be conceived to act, and really does act, without intelligence. There is no reason, however, to suppose, with some, that there are two substances in animals: one possessed of consciousness as its essence, and therefore called *mind* or *soul* in man; another, destitute of conciousness, called the *living principle*, &c. employed in performing the different functions of assimilation, absorption, &c. It is much more reasonable to suppose, that in every animal and vegetable there is a peculiar substance, different from matter, to which their peculiar properties are owing; that this substance is different in every species of animal and vegetable; that it is capable of acting according to certain fixed laws which have been imposed upon it by its Creator, and that these laws are of such a nature that it acts in subservience to a particular end; that this substance in plants is probably destitute of intelligence; that in man and other animals it possesses intelligence to a certain extent, but that this intelligence is not essential to its existence nor to its activity; that it may be deprived of intelligence altogether, and afterwards recover it without altering its nature. Physiologists have given it the name of *living principle*, because its presence constitutes life. Perhaps it would be proper to distinguish that of animals by the name of *animal principle*. Upon what the intelligence of the animal principle depends, it is impossible to say; but it is evidently connected with the state of the brain. During a trance, or an apoplectic fit, it has often been lost for a time, and afterwards recovered.

370 Secretion.

17. Besides assimilation, the blood is also employed in forming all the different secretions which are necessary for the purposes of the animal economy. These have been enumerated in the last chapter. The process is similar to that of assimilation, and undoubtedly the agents in both cases are the same; but we are equally

Decomposition of Animal Substances.

equally ignorant of the precise manner in which secretion is performed as we are of assimilation.

18. After these functions have gone on for a certain time, which is longer or shorter according to the nature of the animal, the body gradually decays, at last all its

Animals at length die and why.

functions cease completely, and the animal dies. The cause of this must appear very extraordinary, when we consider the power which the animal has of renewing decayed parts; for it cannot be doubted that death proceeds, in most cases at least, from the body becoming incapable of performing its function. But if we consider that this power is limited, and that it must cease altogether, when those parts of the system begin to decay which are employed in preparing materials for future assimilation, our surprise will, in some measure, cease. It is in these parts, in the organs of digestion and assimilation accordingly, that this decay usually proves fatal. The decay in other parts destroys life only when the waste is so rapid that it does not admit of repair.

What the reason is that the decay of the organs causes death, or, which is the same thing, causes the living principle either to cease to act, or to leave the body altogether, it is perfectly impossible to say, because we know too little of the nature of the living principle, and of the manner in which it is connected with the body. The last is evidently above the human understanding, but many of the properties of the living principle have been discovered; and were the facts already known properly arranged, and such general conclusions drawn from them as their connection with each other fully warrant, a degree of light would be thrown upon the animal economy which those, who have not attended to the subject, are not aware of.

No sooner is the animal dead, than the chemical and mechanical agents, which were formerly servants, usurp the supreme power, and soon decompose and destroy that very body which had been in a great measure reared by their means. But the changes which take place upon animal bodies after death, are too important, and too intimately connected with the subject of this article to be passed over slightly. They shall therefore form the subject of the next chapter.

Chap. IV. Of the Decomposition of Animal Substances.

372 Decomposition of animal substances exposed to the air.

All the soft and the liquid parts of animals, when exposed to a moderate temperature of sixty-five degrees or more, pass with more or less rapidity through the following changes. Their colour becomes paler, and their consistence diminishes; if it be a solid part, such as flesh, it softens, and a serous matter sweats out, whose colour quickly changes; the texture of the part becomes relaxed, and its organization destroyed; it acquires a faint disagreeable smell; the substance gradually sinks down, and is diminished in bulk; its smell becomes stronger and ammoniacal. If the subject be contained in a close vessel, the progress of putrefaction, at this stage, seems to slacken; no other smell but that of a pungent alkali is perceived; the matter effervesces with acids, and converts syrup of violets to a green. But if the communication with the air be admitted, the urinous exhalation is dissipated, and a peculiar putrid smell is spread around with a kind of impetuosity; a smell of the most insupportable kind, which lasts a long time, and pervades every place, affecting the bodies of living animals after the manner of a ferment, capable of altering the fluids: this smell is corrected, and as it were confined by ammonia. When the latter is volatilized, the putrefactive process becomes active a second time, and the substance suddenly swells up, becomes filled with bubbles of air, and soon after subsides again. Its colour changes, the fibrous texture of the flesh being then scarcely distinguishable; and the whole is changed into a soft, brown, or greenish matter, of the consistence of a poultice, whose smell is faint, nauseous, and very active on the bodies of animals. The odorant principle gradually loses its force; the fluid portion of the flesh assumes a kind of consistence, its colour becomes deeper, and it is finally reduced into a friable matter, rather deliquescent, which being rubbed between the fingers, breaks into a coarse powder like earth. This is the last state observed in the putrefaction of animal substances; they do not arrive at this term but at the end of a considerable time †.

† Fourcroy.

373 Buried in the earth.

In carcases buried in the earth, putrefaction takes place much more slowly; but it is scarcely possible to observe its progress with accuracy. The abdomen is gradually dilated with elastic fluids which make their appearance in it, and at last it bursts and discharges a horribly fetid and noxious gas; at the same time a dark coloured liquid flows out. If the earth be very dry, and the heat considerable, the moisture is often absorbed so rapidly, that the carcase, instead of putrefying, dries, and is transformed into what is called a *mummy*.

374 When accumulated together,

Such are the phenomena when dead bodies are left to putrefy separately. But when great numbers of carcases are crowded together in one place, and are so abundant as to exclude the action of external air, and other foreign agents, their decomposition is entirely the consequence of the reciprocal action of their ingredients themselves upon each other, and the result is very different. The body is not entirely dissipated or converted into mould, but all the soft parts are found diminished remarkably in size, and converted into a peculiar *saponaceous matter*. This singular change was first accurately observed in the year 1786.

375 Converted into a saponaceous matter.

The burial ground of the Innocents in Paris having become noxious to those who lived in its neighbourhood, on account of the disagreeable and hurtful odour which it exhaled, it was found necessary to remove the carcases to another place. It had been usual to dig very large pits in that burial ground, and to fill them with the carcases of the poorer sort of people, each in its proper bier; and when they were quite full, to cover them with about a foot depth of earth, and to dig another similar pit, and fill it in the same manner. Each pit held between 1000 and 1500 dead bodies. It was in removing the bodies from these pits that this saponaceous substance was found. The grave-diggers had ascertained, by long experience, that about thirty years were required before all the bodies had undergone this change in its full extent *. Every part of the body acquired the properties of this substance. The intestines and viscera of the thorax had completely disappeared; but what is singular enough, the brain had lost but little of its size or appearance, though it was also converted into the same substance.

* Fourcroy, Ann. de Chim. v. 154.

376 Its properties.

This saponaceous matter was of a white colour, soft and unctuous to the touch, and melted, when heated, like

like tallow. It exhibited all the properties of a *foap*, containing, however, an excefs of fatty matter. Fourcroy, who analyfed it, found that it was compofed of a fatty matter combined with ammonia, and that it contained alfo fome phofphat of lime and ammonia. Diluted acids decompofed it, and feparated the fatty matter: alkalies and lime, on the other hand, drove off the ammonia. When expofed to the air, it gradually loft its white colour; the ammonia, in a great meafure, evaporated, and what remained had fomething of the appearance of wax. It abforbed water with great avidity, and did not part with it readily. Its white colour was owing to the prefence of that liquid. The oily matter, when feparated by means of a diluted acid, was concrete, and of a white colour, owing to the mixture of a quantity of water. When dried, it acquires a greyifh brown colour, a lamellar and cryftalline texture, like that of fpermaceti; but if it has been rapidly dried it affumes the appearance of wax It melts, when heated, to 126°; when properly purified, by paffing it through a linen cloth while fluid, it has fcarcely any fmell. Alcohol does not act upon it while cold, but at the temperature of 120° it diffolves it: when the folution cools, the fatty matter precipitates, and forms a gritty mafs. With alkalies it forms a foap; and when fet on fire it burns precifely like oil or fat, only that it exhales a more unpleafant odour †.

† *Fourcroy, Ann. de Chim.* viii. 17.

377
Produced alfo in running water.

Mr Smith Gibbes found the fame fubftance in the pit into which animal matters are thrown at Oxford after diffection. A fmall ftream of wate[illegible]ly paffes through this pit; a circumftance whic[illegible] him to try whether animal mufcle expofed to the action of a running ftream underwent the fame change. The experiment fucceeded completely: he attempted, in confequence, to render this fubftance, to which he gave the name of *fpermaceti*, ufeful in thofe manufactures which required tallow; but the fetid odour which it conftantly exhales was an infurmountable objection. Attempts were indeed made to get over it; but as we do not hear that Mr Smith Gibbes's fpermaceti has been introduced into any manufacture, we have reafon to conclude that none of thefe attempts fucceeded ‡.

‡ *Phil. Tranf.* 1794 and 1795.

Such are the phenomena of putrefaction, as far as they are at prefent known to chemifts. Any attempt to explain the manner in which thefe changes take place, would be exceedingly imperfect indeed; not only becaufe we are ignorant of the ftrength of the affinities of the different elementary parts of animal bodies for each other, but becaufe we do not even know the manner in which thefe elements are combined, and confequently we cannot know by what particular forces thefe compounds are deftroyed. We know only that a certain degree of heat, and the prefence of moifture, are in all cafes neceffary for the putrefactive procefs; for animal bodies may be kept almoft any length of time, without decompofition, at the freezing temperature; and when dried quickly, and kept in that ftate, they undergo no farther change.

PART III. OF DYEING.

MANKIND have in all periods of fociety manifefted a fondnefs for beautiful and gaudy colours. Naked favages at firft applied them to their fkin. This was the cafe with the Britons, and with the Gauls, too, in the time of Cæfar; it is even ftill the practice in the South Sea iflands, and many parts of America. When mankind had advanced fo far towards civilization as to wear garments, they naturally transferred to them the colours which they admired. Hence the origin of *dyeing*; which is of fuch antiquity, that it precedes the earlieft records left us by profane authors. We fee from the book of Genefis the great progrefs which it had made in the time of the patriarchs.

379
Origin of dyeing.

Dyeing feems to have originated in India, and to have fpread gradually from that country to the weft. The Indians were the inventors of the method of dyeing cotton and linen, which was not underftood in Europe before the conquefts of Alexander the Great. The Phenicians excelled in the art at a very early period. It was from them that the Jews purchafed all the dyed ftuffs defcribed in Exodus. The Phenician dyers feem to have confined their art to wool: filk was unknown to them, and linen was ufually worn white. From them the art of dyeing paffed to the Greeks and Romans.

During the fifth century, the Weftern Empire was overturned by the northern nations, and with it the arts and fciences, which had flourifhed under the protection of the Romans, difappeared. A few of the arts, indeed, were preferved in Italy, but they were obfcured and degraded. By degrees, however, a fpirit of induftry began to revive in that country. Florence, Genoa, and Venice, becoming rich commercial cities, carried on a confiderable intercourfe with the Grecian empire, where many of the arts had been preferved. This intercourfe was much increafed by the crufades. The Italian cities became rich and powerful: the arts which diftinguifh civilized nations were cultivated with emulation, and dyeing, among others, was rapidly improved.

380
Its progrefs in modern Europe.

In the year 1429, the firft treatife on dyeing made its appearance at Venice, under the name of *Moriegola dell'arte de tentori*. Giovanne Ventura Rofetta collected, with great induftry, all the proceffes employed by the dyers of his time, and publifhed them in 1548, under the title of *Plictho* *. For many years dyeing was almoft exclufively confined to Italy; but it gradually made its way to France, the Low Countries, and to Britain. The minifter Colbert, who employed his talents in extending the commerce and manufactures of France, paid particular attention to the art of *dyeing*. In the year 1672, he publifhed a table of inftructions, by which thofe who practifed the art were laid under feveral very improper reftrictions. But the bad effects of thefe were in a good meafure obviated by the judicious appointment of men of fcience to fuperintend the art. This plan, begun by Colbert, was continued by the French government. Accordingly, Dufay, Hellot, Macquer, and Berthollet, fucceffively filled the office. It is to this eftablifhment, and to exertions of the celebrated chemifts who have filled it, that France is indebted for the improvements fhe has made in the art of dyeing during the courfe of the 18th century. Under the direction of Dufay, a new table of regulations was publifhed in 1737, which fuperfeded that of Colbert. Hellot,

* *Berthollet on Dyeing*, i. 22.

Substances used for Clothing.

Hellot, his successor, published, in 1740, an excellent system of dyeing wool; and Macquer in 1763 published his treatise on dyeing silk.

In Britain, though dyeing has been carried on for many years with great success, very little progress was made in investigating the theory of the art. The Royal Society, indeed, soon after its institution, recommended it to some of its members; but as no treatise made its appearance in consequence of this, it seems very soon to have lost their attention. Lewis, many years after, published some very important remarks on dyeing; but they were confined to a few processes. The British dyers satisfied themselves with a translation of Hellot. Such was the state of the art when the article DYEING in the *Encyclopædia* was drawn up. It consists chiefly of an abstract of Hellot's treatise. But within the last 30 years, the attention of men of science has been very much turned to this complicated art. In Sweden has appeared the treatise of Scheffer, and Bergman's notes on it; in Germany, the experiments of Beckmann, Poerner, and Vogler, and the dissertation of Francheville; in France, the treatises of D'Ambournay, D'Apligny, Hauffmann, Chaptal, and, above all, of Berthollet; in this country, the ingenious remarks of Delaval, of Henry, and the valuable treatise of Dr Bancroft; besides many other important essays. These, together with the progress of the science of chemistry, on which the theory of dyeing depends, have thrown so much new light upon the art, that we find ourselves under the necessity of tracing the whole over again. We shall pass over, however, very slightly those parts of the art which have been sufficiently explained in the article DYEING, *Encycl.*

To understand the art of *dyeing*, we must be acquainted with the *substances* on which it is practised, with the nature of *colour*, and with the method of permanently changing the colour of bodies. These three things we shall consider in the three following chapters. In the first, we shall give an account of the substances of which garments are usually made, with which alone the art of dyeing is concerned; in the second, we shall inquire into the nature of colour; and in the third, explain the theory of dyeing, as far as it is at present understood. In some subsequent chapters, we shall give a general view of the processes by which the different colours are given to stuffs.

CHAP. I. OF THE SUBSTANCES USED FOR CLOTHING.

381 Clothing

THE substances commonly employed for clothing may be reduced to four; namely *wool*, *silk*, *cotton*, *linen*. As there is no name in the English language which includes all these substances, we shall take the liberty, in the remainder of this article, to use the word *cloth* for that purpose. They are all made into *cloth*, of some kind or other, before they can be useful as articles of *clothing*.

382 Consists of wool,

1. WOOL, as is well known, is the hair which covers the bodies of sheep; it differs from common *hair* merely in fineness and softness. Its filaments possess a considerable degree of elasticity; they may be drawn out beyond their usual length, and afterwards recover their form, when the external force is removed. The surface of wool and hair is by no means smooth: No inequality, indeed, can be perceived by a microscope; nor is any resistance felt when a hair is laid hold of in one hand, and drawn between the fingers of the other, from the *root* towards the *point*; but if it be drawn from the *point* towards the *root*, a resistance is felt which did not take place before, a tremulous motion is perceived, and a noise may be distinguished by the ear. If, after laying hold of a hair between the thumb and fore finger, we rub them against each other in the longitudinal direction of the hair, it acquires a progressive motion *towards the root*; the *point* gradually approaches the fingers, while the *root* recedes from them; so that the whole hair very soon passes through between the fingers.

These observations, first made by Mr Monge, demonstrate that the surface of hair and wool is composed, either of small laminæ, placed over each other in a slanting direction from the root towards the point, like the scales of a fish—or of zones, placed one above another, as takes place in the horns of animals *.

On this structure of the filaments of hair and wool depend the effects of *felting* and *fulling*. In both of these operations, the filaments are made, by an external force, to rub against each other; the position of their asperities prevents them from moving, except in one direction: they are mutually entangled, and obliged to approach nearer each other. Hence the thickness which cloth acquires in the fulling mill. The filaments have undergone a certain degree of felting, and are interwoven like the fibres of a hat. The cloth is contracted both in length and breadth: it may be cut without being subject to ravel; nor is there any necessity for hemming the different pieces employed to make a garment. See FELTING and FULLING, in this *Suppl.*

* Ann. de Chim. vi. 300.

Wool is naturally covered with a kind of grease, which preserves it from moths. This is always removed before the wool is dyed; because its presence is very prejudicial to the success of that operation. The asperities of the surface of woolly fibres would impede the converting of it into thread by spinning; but they are in a great measure covered, previous to that operation, by soaking the wool with oil. The oil must also be removed before the wool be dyed. This process is called SCOURING, which see in this *Suppl.*

We have already, in the second part of this article, given an account of what is at present known concerning the composition of wool and hair. It would be foreign to the subject of this chapter, to describe the method of *spinning* and *weaving* wool.

Wool is of different colours; but that which is white is preferred for making cloth; because it answers better for the purposes of dying than any other kind.

383 Silk,

2. SILK is a substance spun in fine threads by the *silk worm*. Its fibres are not scaly like those of wool; neither have they the same elasticity: but silk, in its natural state, before it has undergone any preparation, has a considerable degree of stiffness and elasticity. In this state it is known by the name of *raw silk*. It is covered with a kind of gummy varnish, which may be removed by scouring with soap. The scouring deprives it of its stiffness and elasticity. Raw silk is of a yellow colour, owing to yellow resinous matter with which it is naturally combined. We have given the method of separating this matter, and also the gum, in the article BLEACHING, *Supplement*.

Silk, before it is dyed, is always freed from its gum, and generally also from its resin. It may be dyed with-

out

Substances [...] out the application of heat; which is not the case with wool.

3. COTTON is a fine downy substance, contained in the pods of different species of gossypium. The species from which the greater part of the cotton brought to this country is taken is the *herbaceum*. The quantity imported annually into Britain is very great; in 1786 it amounted to 20 millions of pounds ‡. Cotton varies greatly, according to the plant on which it grows, and the climate where it is cultivated. The chief differences are in colour, and in the length, fineness, and strength of the filaments.

384 Cotton.

‡ *Bancroft*, i. 69.

No asperities can be discovered on the surface of these filaments; but Lewenhoeck observed, by means of a microscope, that they are triangular, and have three sharp edges. This is probably the reason of a well known fact, that cotton cloth, when applied by way of dressing, always irritates a sore.

Some cottons are naturally white; others a fine light yellow, as those of which nankeen is made; but most commonly cotton is of a dirty brownish yellow colour, which must be removed before the stuff can be dyed. This is done by the process of *bleaching*. The fibres of cotton, even after being bleached, retain almost always some lime and oxyd of iron, which must be removed before we attempt to dye the cotton; because their presence would spoil the colour. This is done by steeping the cotton for some time in water acidulated with sulphuric acid.

Cotton, like silk, may be dyed without the assistance of heat. It is not nearly so easy to dye cotton any particular colour as it is to dye wool or silk. If wool and cotton be put into the same dyeing vessel, the wool frequently acquires the wished-for colour before the cotton has lost any of its original whiteness.

385 Linen.

4. LINT, from which *linen* is made, is the inner bark of the *linum usitatissimum*, or *flax*; a plant too well known in this country to require any description.

The flax, when ripe, is pulled and steeped for some days in water, in order to separate the green coloured glutinous matter which adheres to the inner bark. This matter undergoes a degree of putrefaction; carbonic acid gas and hydrogen gas, are disengaged*: it is decomposed, and carried off by the water. If the water, in which the flax is steeped, be completely stagnant, the putrefaction is apt to go too far, and to injure the fibres of the lint; but in a running stream, it does not go far enough, so that the green matter still continues to adhere to the lint. Flax, therefore, should be steeped in water neither completely stagnant, nor flowing too freely, like a running stream.

The flax is afterwards spread upon the grass, and exposed for some time to the air and sun: this improves the colour of the lint, and renders the woody part so brittle, that it is easily separated by the action of the lint mill. The subsequent operations, of *dressing*, *spinning*, *weaving*, and *bleaching*, do not belong to this article.

The fibres of lint have very little elasticity. They appear to be quite smooth; for no asperities can be perceived by the microscope, nor detected by the feel; nor does linen irritate sores, as is the case with cotton.

Linen may be dyed without the assistance of heat; but it is more difficult to give it permanent colours than even cotton.

Thus we have given a short description of wool, silk, cotton, and linen. The first two are animal substances; the two last vegetable. The animal contain much azot and hydrogen; the vegetable much carbon: The animal are readily destroyed by acids and alkalies; the vegetable withstand the action of these substances better; even nitric acid does not readily destroy the texture of cotton. The animal substances are more easily dyed than the vegetable, and the colours which they receive are more permanent than those given to cotton and linen by the same processes.

Such are the properties of the cloths on which the art of dyeing is exercised. But what is the nature of these *colours* which it is the object of that art to communicate? We shall examine this subject in the following chapter.

CHAP. II. OF COLOURS.

ALL visible objects, as has been long ago sufficiently established, are seen by means of rays of light passing off from them in all directions, and partly entering the eye of the spectator.

1. For the theory of light and vision we are indebted to Sir Isaac Newton. He first demonstrated, that light is composed of seven rays, differing from each other in refrangibility, and other properties. Each of these rays is distinguished by its particular colour. These are their names, red, orange, yellow, green, blue, indigo, violet. By mixing together these different rays, in various proportions, all the colours known may be obtained. Thus red and yellow constitute orange; yellow and blue constitute green; blue and red constitute purple, violate, aurora, &c. according to their proportions. When all the rays are mixed together, they form a white. 386 Colours produced by [...]

2. Bodies differ very much from each other in their power of reflecting light. Some reflect it in vast quantity, as metals; others reflect but little, as charcoal. In general, the smoother the surface of a body is, the greater is the quantity of light which it reflects. Hence the effect of polishing in increasing the brightness of bodies. But it is not in the quantity of the light reflected alone that bodies differ from each other, they differ also in the quality of the light which they reflect. Some bodies reflect one or more particular species of ray to the exclusion of the rest. This is the reason that they appear to us of different colours. Those bodies which reflect only red rays are red; those that reflect yellow rays are yellow; those that reflect all the rays equally are white; those that reflect too little to affect the eye are black. It is to the different combinations of rays reflected from the surface of bodies that all the different shades of colour are owing. Bodies reflect different rays.

Colour, then, in *opaque* bodies, is owing to their disposition to *reflect* certain rays of light, and to *absorb* the rest; in *transparent* bodies, to their disposition to *transmit* certain rays, and to *absorb* the others. But this subject has been discussed, at sufficient length, in the article OPTICS, *Encycl.*; to which, therefore, we beg leave to refer the reader. Here we mean only to inquire into the *cause* of this disposition of the particles of bodies. 388 Hence their different colours.

3. Sir Isaac Newton, to whom we are indebted for the existence of optics as a science, made a set of experiments to ascertain the changes of colour which thin plates of matter assume in consequence of an increase or dimi- 389 Newtonian theory to explain this difference

Colours

diminution of their thickneſs. Theſe experiments were of a very delicate nature; but Newton conducted them with ſo much addreſs, and varied and repeated them with ſo much induſtry, that he was enabled to render them ſurpriſingly accurate.

Upon a large double convex lens of a 50 feet focus, he placed the plane ſurface of a planoconvex lens, and preſſed the lenſes ſlowly together. A circle, of a particular colour, appeared in the centre, where the two glaſſes touched each other. This circle gradually increaſed in diameter as the preſſure was augmented; and at laſt a new circle, of another colour, occupied the centre, while the firſt colour aſſumed the form of a circular ring. By increaſing the preſſure, a new coloured circle appeared in the centre, and the diameter of the other two increaſed. In this manner he proceeded, till he produced no leſs than 25 different coloured circular rings. Theſe he divided into ſeven orders, on account of the repetition of the ſame colour. They were as follows, reckoning from the central colour, which was always black *.

* Newton's Optics, 19. Clarke's edition.

1. Black, blue, white, yellow, red.
2. Violet, blue, green, yellow, red.
3. Purple, blue, green, yellow, red
4. Green, red.
5. Greeniſh blue, red.
6. Greeniſh blue, pale red.
7. Greeniſh blue, reddiſh white.

Theſe different colours were occaſioned by the thin film of air between the two glaſſes. Now this film varies in thickneſs from the centre of the lens towards the circumference; that part of it which cauſes the black colour is thinneſt, and the other coloured circles are occaſioned by air gradually increaſing in thickneſs. Newton meaſured the *relative thickneſs* of the air which produced each of theſe coloured circles; and he found it as follows †:

† Ibid. p. 225.

1. Black		1	green	-	25 1/5
blue		2 1/5	yellow	-	27 1/7
white		5 1/5	red	-	31
yellow		7 1/6	4. Green	-	35
red		8 1/3	red	-	40 1/3
2. Violet	-	11 1/6	5. Gr. blue	-	46
blue	-	14	red	-	52 1/2
green		15 1/8	6. Gr. blue	-	58 3/4
yellow	-	16 1/7	red	-	65
red	-	18 1/3	7. Gr. blue	-	71
3. Purple	-	21	reddiſh white		77
blue	-	23 2/5			

The *abſolute* thickneſs of theſe films cannot be aſcertained, unleſs the diſtance between the two glaſſes, at that part where the black ſpot appears, were known. Now there is no method of meaſuring this diſtance; but it certainly is not greater than the thouſandth part of an inch.

He repeated theſe experiments with films of water, and even of glaſs, inſtead of air; and he found, that in theſe caſes the thickneſs of the films, reflecting any particular colour, was diminiſhed, and that this diminution was proportional to the denſity of the reflecting film.

Colours.

From theſe experiments Sir Iſaac Newton concluded, that the diſpoſition of the particles of bodies to reflect or tranſmit particular rays depended upon their ſize and their denſity: and he even attempted to aſcertain the ſize, or at leaſt the thickneſs, of the particles of bodies from their colours. Thus a particle of matter, whoſe denſity is the ſame with that of glaſs which reflects a green of the third order, is of the thickneſs of $\frac{16\frac{1}{4}}{1000000}$ of an inch *.

* Newton's Optics, 251.

In the year 1765, Mr Delaval publiſhed, in the Philoſophical Tranſactions, a very ingenious paper on the ſame ſubject. In this paper, he endeavours to prove, by experiment, that the colours of metallic bodies depend upon their denſity. He takes it for granted, at the ſame time, that the ſize of the particles of bodies is inverſely as the denſity of bodies. The denſeſt bodies, according to him, are red; the next in denſity, orange; the next, yellow; and ſo on, in the order of the refrangibility of the different rays. Some time after, the ſame ingenious gentleman, in his *Experimental Inquiry into the Cauſe of the Permanent Colours of Opaque Bodies*, extended his views to animal and vegetable ſubſtances, and endeavoured to prove the truth of Newton's theory by a very great number of experiments.

Such is a view of the opinion of Newton and Delaval reſpecting the cauſe of bodies reflecting or tranſmitting particular rays of light, as far, at leaſt, as that theory relates to colour. They aſcribed this cauſe *ſolely* to the *ſize* and the *denſity* of the particles of bodies.

By *particles*, it is evident that nothing elſe can be meant than the *integrant particles* of bodies. Newton, indeed, does not expreſs himſelf preciſely in this language; but it is plain that nothing elſe could be his meaning. Mr Delaval undoubtedly is of that opinion.

According to the Newtonian theory of colour, then, it depends ſolely upon the *ſize* of the integrant particles of bodies whoſe denſity is the ſame; and upon the *ſize* and the *denſity* jointly of all bodies (T).

390 Examined.

It is evident that the truth of the Newtonian theory muſt depend upon its coincidence with what actually takes place in nature, and that therefore it can only be determined by experiment. Newton himſelf produced but very few experiments in ſupport of it; and though this deficiency was amply ſupplied by Mr Delaval, it is needleſs for us to adduce any of theſe here; becauſe, from the prodigious accumulation of chemical facts ſince theſe experiments were made, the very baſis upon which they ſtood has been deſtroyed, and conſequently all the evidence reſulting from them has been annihilated. They proceeded on the ſuppoſition, that acids render the particles of bodies *ſmaller*, and alkalies *larger* than they were before, without producing any other change whatever in the bodies on which they act. To attempt a refutation of this opinion at preſent would be unneceſſary, as it is well known not to be true.

Let us therefore compare the Newtonian theory of colour with thoſe chemical changes which we know for certain to alter the ſize of the particles of bodies, in order to ſee whether they coincide with it. If the theory be true, the two following conſequences muſt hold

(T) Newton, however, pointed out an exception to this law, concerning which Mr Delaval has been more explicit. Combuſtible bodies do not follow that law, but ſome other. Mr Delaval has ſuppoſed, that this deviation is owing to the preſence of phlogiſton.

Colours. hold in all cases: 1. Every alteration in the size of the integrant particles of bodies must cause these particles to assume a different colour. 2. Every such alteration must correspond precisely with the theory; that is to say, the new colour must be the very colour, and no other, which the theory makes to result from an increase or diminution of size.

391 And found defective. Now neither of these consequences holds in fact. We have no method indeed of ascertaining the sizes of the integrant particles of bodies, nor of measuring the precise degree of augmentation or diminution which they suffer; but we can in many cases ascertain, whether any new matter has been added to a particle, or any matter abstracted from it; and consequently whether it has been augmented or diminished; which is sufficient for our present purpose.

For instance, whatever be the size of an integrant particle of gold, it cannot be denied that an integrant particle of oxyd of gold is greater; because it contains an integrant particle of gold combined with at least one integrant particle of oxygen. Now the colour both of gold and of its oxyd is yellow, which ought not to be the case, according to the Newtonian theory. In like manner, the amalgam of silver is white, precisely the colour of silver and of mercury; yet an integrant particle of the amalgam must be larger than an integrant particle either of silver or of mercury. Many other instances besides these will occur to every one, of changes in the size of the particles taking place without any change of colour. All these are incompatible with the Newtonian theory.

It may be said, perhaps, in answer to this objection, that there are different orders of colours; that the same colour is reflected by particles of different sizes; and that the increased particles, in the instances above alluded to, retain their former colour, because the increment has been precisely such as to enable them to reflect the same colour in the next higher order.

This very answer is a complete proof that the Newtonian theory is not sufficient to account for the colours of bodies; for if particles of *different* sizes reflect the same colour, *size* certainly is not the only cause of this reflection *. There must be some other cause very different from size. Nor is this all; the most common colour which remains after an increase of the size of the integrant particles of bodies is white; yet white does not appear in any of the orders except the first, and therefore its permanence cannot be accounted for by any supposition compatible with the Newtonian theory.

* *Bancroft on Permanent Colours*, i 7.

Even when alterations in the colour of bodies accompany the increase or diminution of the size of their particles, these alterations seldom or never follow an order which corresponds with the theory. As for metals, it is self-evident that their colour does not depend upon their density. Platinum is the densest body known, and yet it is not red, as it ought to be, but white like tin; a metal which has little more than one third of the density of platinum.

The green oxyd of iron, when combined with prussic acid, becomes white; yet the size of its particles must be increased. Now this change of colour is incompatible with the theory; for, according to it, every change from green to white ought to be accompanied by a diminution instead of an increase of size. A particle of indigo, which is naturally green, becomes blue by the addition of oxygen, which must increase its size. This change is also incompatible with the theory. But it is unnecessary to accumulate instances, as they will naturally occur in sufficient number to every one.

It follows irresistibly from these facts, that the Newtonian theory is not sufficient to explain the *cause* of colour; or what causes bodies to reflect or transmit certain rays, and to absorb the rest.

4. We have endeavoured, in the article CHEMISTRY, *Suppl.* to shew, that bodies have a particular affinity for the rays of light; and that the phenomena of light depend entirely upon these affinities. Indeed this consequence follows from the properties of light established by Newton himself. We shall not repeat here the proofs upon which the existence of these affinities is founded: the reader may easily satisfy himself by consulting the article above referred to. 392 Bodies owe their colour to their affinity for light.

Every coloured body, then, has a certain *affinity for* some of the rays of light. Those rays for which it has a strong affinity are absorbed by it and retained, and the other rays for which it has no affinity are either reflected or transmitted, according to the nature of the body and the direction of the incident ray. Thus a red body has an affinity for all the rays except the red; it absorbs therefore the other six, and reflects only the red: a green body absorbs all but the green rays, or perhaps the red and yellow: a black body has a strong affinity for all the rays, and therefore absorbs them all: while a white body, having no strong affinity for any of the rays, reflects or transmits them all.

If affinity, as we have endeavoured to shew in the article CHEMISTRY, *Suppl.* be an attraction of the same nature with gravitation, and increasing as the distance diminishes, it must depend upon the nature of the attracting particles. Now the only differences which we can conceive to exist between the particles of bodies, are differences in *size*, in *density*, and in *figure*. Changes in these three things will account for all the varieties of affinity. Now if affinity depends upon these three things, and if colour depends upon the affinity between the particles of bodies and the different rays of light as cannot be denied, it is clear that the cause of the colour of bodies may be ultimately resolved into the size, density, and figure, of their particles. Newton's theory, then, was defective, because he omitted the *figure* of the particles, and ascribed the whole to variations in *size* and *density*.

When we say, then, that colour is owing to *affinity*, we do not contradict the opinion of Newton, as some philosophers have supposed, but merely extend it. Newton was *not mistaken* in saying, that colour depends upon the size and the density of the particles of bodies; his mistake lay in supposing that it depends upon these *alone*.

5. Since the colour of bodies depends upon their affinity for light, and since every body has a certain colour, because it absorbs and retains particular rays while it transmits or reflects the rest, it is evident that every body must continue of its first colour till one of two things happen; either till it be saturated with the rays which it absorbs, and of course cease to absorb any more, or till its particles change their nature, by being either decomposed or combined with some new substance. We have no positive proof that the first cause 393 Why bodies change their colours.

Colours. cause of change ever occurs, as many substances have been exposed to the action of light for a very long time without any change of colour. The absorbed light seems to make its escape, either in its own form, or in some unknown or unsuspected one. The second cause of change is very common: indeed its action may be detected in almost every case of alteration in the colour of bodies. The green oxyd of iron, by combining with oxygen, becomes red; and this red oxyd, when combined with prussic acid, assumes a blue colour, and with gallic acid a black colour. The cause of this change of colour, when the composition of a body changes, is obvious: every change of composition must alter the affinity, because it must of necessity produce changes in the size, density, or figure of the particles, or perhaps in all of these. Now if the affinity of a body for other bodies be altered, it is natural to suppose that it will be altered also for light. Accordingly this happens in most instances. It does not, however, take place constantly, for very obvious reasons. It may happen that the new density, size, or figure of the altered body is such, as to render it still proper for attracting the very same rays of light which it formerly attracted. Just as iron, after being combined with a certain dose of oxygen, is converted into green oxyd, which still retains an affinity for oxygen.

It is evident from all this, that in most cases the permanence of colour in bodies will depend upon the permanence of their composition, or on the degree of facility with which they are acted upon by those bodies, to the agency of which they are exposed.

394 Permanency of colour of great importance in *dyeing*.

In *dyeing*, the permanence of colour is of very great importance. Of what value is the beauty of a colour, provided that colour be fugitive or liable to change into some other. In all cases, therefore, it is of consequence to attend to the substances to which dyed cloth is exposed, and to ascertain their action upon every particular dyeing ingredient. Now the bodies to which dyed cloth is almost constantly exposed are *air* and *light*; the combined action of which has so much influence, that very few dyes can resist it.

395 How dyes lose their colour.

It is evident that those substances which have a strong affinity for oxygen cannot retain their colour, provided they be able to take it from atmospheric air. Thus the green colour of green oxyd of iron and of indigo is not permanent, because these substances readily absorb oxygen from air. In order, then, that a colour can have any permanence, the coloured body must not have so great an affinity for oxygen as to be able to take it from air. Those bodies have in general the most permanent colours which are already saturated with oxygen, and therefore not liable to absorb more. Such is the case with red oxyd of iron.

All coloured bodies are compounds; some of those only excepted which still retain an affinity for oxygen. Coloured bodies, therefore, are composed of several ingredients; and in every coloured body, at least *some* of the ingredients have a strong affinity for oxygen. Now, before the colour of a body can be permanent, its ingredients must be combined together by so strong affinities, that oxygen gas is unable to decompose it by combining with one or more of its ingredients and carrying it off. If this decomposition take place at once, it is impossible for the colour of a body to have any permanence. If it takes place slowly, the colour of the body gradually decays. The action of oxygen gas upon bodies is much increased in particular circumstances. Almost all coloured bodies are decomposed by oxygen gas by the assistance of heat. Thus if wheat flour be exposed to the heat of 448°, it loses its white colour, and becomes first brown and then black. At this temperature it is decomposed, and a part, or even the whole of its hydrogen, combining with oxygen, flies off. Cloth is scarcely ever exposed to so high a temperature; but there are other circumstances in which it may be placed which may have a similar effect. Thus the action of light seems in some substances to be similar to that of heat, and to facilitate the decomposition of the coloured matter by the combination of some of its ingredients with oxygen *.

* Berthollet on Dyeing, i. 45.

Coloured bodies, in order to have permanent colours, must not be liable to be decomposed by other substances more than by oxygen. For instance, if they contain oxygen and hydrogen, these two bodies must not be liable to combine together and form water, nor must oxygen and carbon be liable to combine and form carbonic acid gas. Light seems to have a tendency to decompose many bodies in this manner, and even to carry off oxygen from them in the form of oxygen gas. Thus it renders the nitrat of silver black by carrying off part of its oxygen, and it reduces oxy-muriatic acid to common muriatic acid by the same means.

These are the causes which induce a change in the colour of coloured bodies, as far as they have been traced; namely, the addition of oxygen, the abstraction of oxygen, partial decomposition by some one of their ingredients combining with oxygen, complete or partial decomposition by the ingredients entering into new combinations with each other. The coloured matters used in dyeing are very liable to these changes, because they are in general, animal or vegetable substances of a very compound nature. Of course their ingredients have often no very strong affinity for each other, and therefore are very liable to decomposition; and every one of the ingredients has in general a very strong affinity for oxygen. This renders the choice of proper colouring matters for dyeing a very important point. In order to have permanency, they must not be liable to the above changes, not to mention their being able also to withstand the action of soap, acids, alkalies, and every other substance to which dyed cloth may be exposed.

396 Method of ascertaining the permanency of dyes.

It becomes therefore a point of some consequence to be able to ascertain whether cloth dyed of any particular colour be permanently dyed or not. The proper method of ascertaining this is by actually exposing such cloth to the sun and air; because as these are the agents to which it is to be exposed, and which have the most powerful action, it is clear, that if it withstand them, the colour must be considered as permanent. But this is a tedious process. Berthollet proposed exposing such cloth to the action of oxy-muriatic acid; those colours that withstand it being considered as permanent. This method answers in many cases: but it is not always to be depended on; for it destroys some permanent colours very speedily, and does not alter others which are very fading *. But we shall have occasion to resume this subject afterwards.

* Bancroft, i. 49.

397 Division of colours.

Dyers divide colours into two classes; namely, *simple* and *compound*. The simple colours are those which cannot

Dyeing in General. cannot be produced by the mixture of other colours. They are in number four.

1. Blue, 3. Red,
2. Yellow, 4. Black.

Some add a fifth, *brown*; but it may be produced by combining two others.

The compound colours are those which are produced by mixing together any two simple colours in various proportions. They constitute all the colours except the four simple and their various shades.

Thus we have examined the nature of colours; but we have still to explain the method of giving permanent colours to cloth. This shall be the subject of the next chapter.

Chap. III. Of Dyeing in General.

From the theory of colour laid down in the last chapter, it follows, that permanent alterations in the colour of cloth can only be induced two ways; either by producing a chemical change in the cloth, or by covering its fibres with some substance which possesses the wished-for colour. Recourse can seldom or never be had to the first method, because it is hardly possible to produce a chemical change in the fibres of cloth without spoiling its texture and rendering it useless. The dyer, therefore, when he wishes to give a new colour to cloth, has always recourse to the second method.

398 Dye-stuffs

1. The substances employed for this purpose are called *colouring matters*, or *dye stuffs*. They are for the most part extracted from *animal and vegetable substances*, and have usually the colour which they are intended to give to the cloth. Thus a blue colour is given to cloth by covering its fibres with indigo, a blue powder extracted from a shrub; a red colour, by the colouring matter extracted by water from an insect called *cochineal*, or from the root of a plant called *madder*.

399 Do not reflect light.

2. Mr Delaval has published a very interesting set of experiments on colouring matters in the second volume of the Manchester Memoirs. He has proved, by a very numerous set of experiments, that they are all transparent, and that they do not *reflect* any light, but only transmit it: For every colouring matter which he tried, even when dissolved in a liquid, and forming a transparent coloured solution, when seen merely by reflected light, was black, whatever was the colour of the matter; but when seen by transmitted light, it appeared of its natural colour *. This discovery, which Mr Delaval has established very completely, and to which, as far at least as dye stuffs are concerned, there are but few exceptions, is of very great importance to the art of dyeing, and explains several particulars which would otherwise be unintelligible.

* *Manch. Mem.* ii. 131.

Since the particles of the colouring matter with which cloth, when dyed, is covered, are transparent, it follows, that all the light reflected from dyed cloth must be reflected, not by the dye stuff itself, but by the fibres of the cloth below the dye stuff. The colour therefore does not depend upon the dye alone, but also upon the previous colour of the cloth. If the cloth be *black*, it that we cannot dye it any colour; because as no light in that case is reflected, none can be transmitted, whatever dye stuff we employ. If the cloth were red, or blue, or yellow, we could not dye it any colour except black; because as only red, or blue, or yellow rays were reflected, no other could be transmitted (x). Hence the importance of a fine white colour when cloth is to receive bright dyes: it then reflects all the rays in abundance; and therefore any colour may be given, by covering it with a dye stuff which transmits only some particular rays.

400 They must be combined with the cloth.

3. If the colouring matters were merely spread over the surface of the fibre of cloth by the dyer, the colours produced might be very bright, but they could not be permanent; because the colouring matter would be very soon rubbed off, and would totally disappear whenever the cloth was washed, or even barely exposed to the weather. The colouring matter, then, however perfect a colour it possesses, is of no value, unless it also adheres so firmly to the cloth, that none of the substances usually applied to cloth in order to clean it, &c. can displace it. Now this can only happen when there is a strong *affinity* between the colouring matter and the cloth, and when they are actually combined together in consequence of that affinity.

401 Can only be applied in a state of solution.

4. Dyeing, then, is merely a chemical process, and consists in combining a certain colouring matter with the fibres of cloth. This process can in no instance be performed, unless the dye stuff be first reduced to its integrant particles; for the attraction of aggregation between the particles of dye stuffs is too great to be overcome by the affinity between them and cloth, unless they could be brought within much smaller distances than is possible, while they both remain in a solid form. It is necessary, therefore, previously to dissolve the colouring matter in some liquid or other, which has a weaker affinity for it than the cloth has. When the cloth is dipped into this solution, the colouring matter, reduced by this contrivance to a liquid state, is brought within the attracting distance; the cloth therefore acts upon it, and by its stronger affinity takes it from the solvent, and fixes it upon itself. By this contrivance, too, the equality of the colour is in some measure secured, as every part of the cloth has an opportunity of attracting to itself the proper proportion of colouring particles.

The facility with which cloth imbibes a dye, depends upon two things, namely, the affinity between the cloth and the dye stuff, and the affinity between the dye stuff and its solvent. It is directly as the former, and inversely as the latter. It is of importance to preserve a due proportion between these two affinities, as upon that proportion much of the accuracy of dyeing depends. If the affinity between the colouring matter and the cloth be too great, compared with the affinity between the colouring matter and the solvent, the cloth will take the dye too rapidly, and it will be scarce possible to prevent its colour from being unequal. On the other hand, if the affinity between the colouring matter and the solvent be too great, compared with that

(x) These remarks hold only on the supposition, that the *whole* of the surface is of the given colour, which in many instances is not the case.

that between the colouring matter and the cloth, the cloth will either not take the colour at all, or it will take it very flowly and very faintly.

Wool has the ftrongeft affinity for almoft all colouring matters, filk the next ftrongeft, cotton a confiderably weaker affinity, and linen the weakeft affinity of all. Therefore, in order to dye cotton or linen, the dye ftuff fho in many cafes be diffolved in a fubftance for which it has a weaker affinity than for the folvent employed in the dyeing of wool or filk. Thus we may ufe oxyd of iron diffolved in fulphuric acid, in order to dye wool; but for cotton and linen, it is better to diffolve it in acetous acid.

402 Nature of mordants.

5. Were it poffible to procure a fufficient number of colouring matters having a ftrong affinity for cloth, to anfwer all the purpofes of dyeing, that art would be exceedingly fimple and eafy. But this is by no means the cafe: if we except indigo, the dyer is fcarcely poffeffed of a dye ftuff which yields of itfelf a good colour fufficiently permanent to deferve the name of a dye.

This difficulty, which at firft fight appears infurmountable, has been obviated by a very ingenious contrivance. Some fubftance is pitched upon which has a ftrong affinity both for the cloth and the colouring matter. This fubftance is previoufly combined with the cloth, which is then dipped into the folution containing the dye ftuff. The dye ftuff combines with the intermediate fubftance; which, being firmly combined with the cloth, fecures the permanence of the dye. Subftances employed for this purpofe are denominated *mordants* (Y).

The moft important part of dyeing is undoubtedly the proper choice and the proper application of mordants, as upon them the permanency of almoft every dye depends. Every thing which has been faid refpecting the application of colouring matters, applies equally to the application of mordants. They muft be previoufly diffolved in fome liquid, which has a weaker affinity for them than the cloth has to which they are to be applied; and the cloth muft be dipped, or even fteeped, in this folution, in order to faturate itfelf with the mordant.

Almoft the only fubftances ufed as mordants are, earths, metallic oxyds, tan, and oil

403 Earthy mordants.

6. Of earthy mordants, by far the moft important and moft generally ufed is alumina. It was ufed as a mordant in very early ages, and feems indeed to have been the very firft fubftance employed for that purpofe. Alumina has a very ftrong affinity for wool and for filk; but its affinity for cotton and linen is a good deal weaker.

It is ufed as a mordant in two ftates; either in the ftate of alum, in which it is combined with fulphuric acid and a little potafs; or in the ftate of acetite of alumina, in which it is combined with acetous acid.

Alum was employed as a mordant very early. The ancients, indeed, do not feem to have been generally acquainted with pure alum, they ufed it in that ftate of impurity in which it is found native; of courfe it was ufed in dyeing long before the nature of its ingredients was underftood, and therefore long before the part which it acts was fufpected. Indeed, it is but a very fhort time fince the office which mordants perform was fufpected: the firft perfon that hit upon it was Mr Keir; he gave an account of the real ufe of mordants in his tranflation of Macquer's Dictionary, publifhed in 1771 *.

* Macquer, p. 215.

Alum, when ufed as a mordant, is diffolved in water, and very frequently a quantity of tartar is diffolved along with it. Into this folution the cloth is put and kept in it till it has abforbed as much alumina as is neceffary. It is then taken out, and for the moft part wafhed and dried. It is now a good deal heavier than it was before, owing to the alumina which has combined with it. The tartar ferves two purpofes: the potafs which it contains combines with the fulphuric acid of the alum, and thus prevents that very corrofive fubftance from injuring the texture of the cloth, which otherwife might happen; the tartarous acid, on the other hand, combines with part of the alumina, and forms a tartrite of alumina, which is more eafily decompofed by the cloth than alum.

Acetite of alumina has been introduced into dyeing fince the commencement of the 18th century; and, like many other very important improvements, we are indebted for it to the ignorance of the calico printers, who firft introduced it. As they did not underftand the nature nor ufe of the mordants which they employed, they were accuftomed to mix with their alum an immenfe farrago of fubftances, a great proportion of which were injurious inftead of being of fervice. Some one or other had mixed with alum acetite of lead: the good effects of this mixture would be foon perceived; the quantity of acetite was gradually increafed, and the other ingredients omitted *. This mordant is now prepared, by pouring acetite of lead into a folution of alum: a double decompofition takes place, the fulphuric acid combines with the lead, and the compound precipitates in the form of an infoluble powder; while the alumina combines with the acetous acid, and remains diffolved in the liquid. This mordant is employed for cotton and linen, which have a weaker affinity than wool for alumina. It anfwers much better than alum, the cloth is more eafily faturated with alumina, and takes, in confequence, both a richer and a more permanent colour.

* Bancroft, p. 176.

Befides alumina, *lime* is fometimes ufed as a mordant. Cloth has a ftrong enough affinity for it; but in general it does not anfwer fo well, as it does not give fo good a colour. When ufed, it is either in the ftate of lime-water or of fulphat of lime diffolved in water.

404 Metallic mordants.

7. Almoft all the metallic oxyds have an affinity for cloth; but only two of them are extenfively ufed as mordants, namely, the oxyds of tin and of iron.

The oxyd of tin was firft introduced into dyeing by Kufter (Z), a German chemift, who brought the fecret to London in 1543. This period forms an era in the hiftory of dyeing. The oxyd of tin has enabled the moderns

(Y) This term, impofed by the French dyers before the action of mordants was underftood, fignifies *biters* or *corroders*. Thefe bodies were fuppofed to act merely by corroding the *cloth*. Mr Henry of Manchefter has propofed to fubftitute the word *bafis* for *mordant*; but that word is too general to anfwer the purpofe well.

(Z) Mr Delaval has fuppofed, that the Tyrians were acquainted with the ufe of tin in dyeing, and Mr Henry

Dyeing in General.

moderns greatly to surpass the ancients in the fineness of their colours: by means of it alone, *scarlet*, the brightest of all colours, is produced. The method of producing the celebrated purple dye of the ancients is understood at present, and the shell fish which yield the dye stuff are found abundantly on the coasts of Britain and France; but no person thinks now of putting the ancient mode in practice, because infinitely more beautiful colours can be produced at a smaller price. Much of this superiority is owing to the employment of the oxyd of tin.

Tin, as Proust has proved, is capable of two degrees of oxydation: The first oxyd is composed of 0.70 parts of tin, and 0.30 of oxygen; the second, or white oxyd of 0.60 parts of tin, and 0.40 of oxygen *. The first oxyd absorbs oxygen with very great facility even from the air, and is rapidly converted into white oxyd. This fact makes it certain, that it is the white oxyd of tin alone which is the real mordant: even if the other oxyd were applied to cloth, as it probably often is, it must soon be converted into white oxyd, by absorbing oxygen from the atmosphere.

* Ann. de Chim. xxviii 213.

Tin is used as a mordant in three states; dissolved in nitro-muriatic acid, in acetous acid, and in a mixture of sulphuric and muriatic acids. Nitro-muriat of tin is the common mordant employed by dyers. They prepare it by dissolving tin in diluted nitric acid, to which a certain proportion of muriat of soda, or of ammonia, is added. Part of the nitric acid decomposes these salts, combines with their base, and sets the muriatic acid at liberty. They prepared it at first with nitric acid alone; but that mode was very defective; because the nitric acid very readily converts tin to white oxyd, and then is incapable of dissolving it. The consequence of which was, the precipitation of the whole of the tin. To remedy this defect, common salt, or sal ammoniac, was very soon added; muriatic acid having the property of dissolving white oxyd of tin very readily. A considerable saving of nitric acid might be obtained, by employing as much sulphuric acid as is just sufficient to saturate the base of the common salt, or sal ammoniac, employed.

When the nitro-muriat of tin is to be used as a mordant, it is dissolved in a large quantity of water, and the cloth is dipped in the solution, and allowed to remain till sufficiently saturated. It is then taken out, and washed and dried. Tartar is usually dissolved in the water along with the nitro-muriat. The consequence of this is a double decomposition; the nitro-muriatic acid combines with the potass of the tartar, while the tartarous acid dissolves the oxyd of tin. When tartar is used, therefore, in any considerable quantity, the mordant is not a nitro-muriat, but a tartrite of tin.

Mr Haussman, to whom the art of dyeing lies under numerous obligations, has proposed to substitute acetite of tin for nitro-muriat as a mordant for cotton and linen. It may be prepared by mixing together acetite of lead and nitro-muriat of tin. This mordant is preferable for these stuffs; because it is much more easily decomposed than the nitro muriat †.

† Ann de Chim. xxx.

Dr Bancroft has proposed to substitute a solution of tin in a mixture of sulphuric and muriatic acid, instead of nitro-muriat of tin, as a mordant for wool. This mordant, he informs us, is much cheaper, and equally efficacious. It may be prepared by dissolving somewhat less than one part of tin in two parts of sulphuric and three of muriatic acid, at the degree of concentration at which they are commonly sold in this country ‡. This mordant, like the others, must be dissolved in a sufficient quantity of water, in order to be used

‡ Bancroft, 293.

Iron, like tin, is capable of two degrees of oxydation; but the green oxyd absorbs oxygen so readily from the atmosphere, that it is very soon converted into the red oxyd. It is only this last oxyd which is really used as a mordant in dyeing. The green oxyd is indeed sometimes applied to cloth; but it very soon absorbs oxygen, and is converted into the red oxyd. This oxyd has a very strong affinity for all kinds of cloth. The permanency of the iron spots on linen and cotton is a sufficient proof of this. As a mordant, it is used in two states; in that of sulphat of iron, and acetite of iron. The first is commonly used for wool. The salt is dissolved in water, and the cloth dipped in it. It may be used also for cotton; but in most cases acetite of iron is preferred. It is prepared by dissolving iron, or its oxyd, in vinegar, sour beer, &c. and the longer it is kept, the more is it preferred. The reason is, that this mordant succeeds best when the iron is in the state of red oxyd. It would be better then to oxydate the iron, or convert it into rust, before using it; which might easily be done, by keeping it for some time in a moist place, and sprinkling it occasionally with water. Of late, pyrolignous acid has been introduced instead of acetous. It is obtained by distilling wood or tar.

405 Tan.

8. Tan, which has been already described in the first part of this article, has a very strong affinity for cloth, and for several colouring matters. It is therefore very frequently employed as a mordant. An infusion of *nut galls*, or of *sumach* (A), or any other substance containing tan, is made in water, and the cloth is dipped in this infusion, and allowed to remain till it has absorbed a sufficient quantity of tan. Silk is capable of absorbing a very great proportion of tan, and by that means acquires a very great increase of weight. Manufacturers sometimes employ this method of increasing the weight of silk §.

§ Berthollet, ii. 10.

Tan is often employed also, along with other mordants, in order to produce a compound mordant. Oil is also used for the same purpose in the dyeing of cotton and linen. The mordants, with which tan most frequently is combined, are alumina and oxyd of iron.

406 Other mordants.

Besides these mordants, there are several other substances frequently used as auxiliaries, either to facilitate the combination of the mordant with the cloth, or to alter

ry has declared himself of the same opinion. But his reasoning, as Dr Bancroft has shewn, proceeds upon a mistake. He supposes that tin is *necessary* for the production of red colours.

(A) Sumach is the *rhus coriaria*; a shrub which is cultivated in the southern parts of Europe. Its shoots are dried, and afterwards ground to powder; in which state they are sold to the dyer and tanner.

Dyeing in General.

alter the shade of colour. The chief of these are, *tartar, acetite of lead, common salt, sal ammoniac, sulphat* or *acetite of copper*, &c.

407 Mordants affect the colour.

9. Mordants not [illegible] render the dye permanent, but have also conside[illegible] influence on the colour produced. The same co[illegible] matter produces very different dyes, according as the mordant is changed. Suppose, for instance, that the colouring matter be cochineal; if we use the aluminous mordant, the cloth will acquire a crimson co[illegible]our; but the oxyd of iron produces with it a black. These changes, indeed, might naturally have been expected: for since the colour of a dye stuff depends upon its affinity for light, every new combination into which it enters, having a tendency to alter these affinities, will naturally give it a new colour. Now, in all cases, the colouring matter and mordant combine together: the colour of the cloth, then, must be that which the particles of the dye and of the mordant, when thus combined together, exhibit. Indeed some mordants may be considered in the light of colouring matters also, as they always communicate a particular colour to cloth. Thus, iron communicates a brown colour, and iron and tan together constitute a black dye.
